Lighting and Continuity of Service

In spite of the great development within the last few years of devices for the protection of electrical apparatus against lightning and the vast improvement in the insulation of transmission lines, this source of disturbance still remains one of the most serious threats against continuity of service in our large overhead systems. In perfecting remedies, or preventatives, it is highly desirable to know the cause and nature of the attack of lightning on the line, for it is on the transmission line rather than in the station, that interruptions to service usually occur.

Lightning *may* as a theoretical matter affect a transmission line either by electrostatic induction; that is, by the release of a bound charge that has been gradually drawn onto the line, or by direct stroke from the atmosphere which may be a heavy and conspicuous stroke or a minor, almost unnoticed flash. As a practical matter, especially when considering the installation of one or more ground wires over a transmission line, it is important to know which sort of action is dominating. Mr. Peek has pointed out that under certain conditions of cloud discharge we may expect a voltage to appear on a transmission line from the release of a bound charge sufficiently high to flash over even a 220-kv. insulator string. Of this there can be little doubt. On the other hand, some considerations may be raised tending to indicate that the line will in all probability actually be subject to direct strokes, *usually of a minor magnitude.* This may be reasoned as follows:

It can hardly be doubted that on all occasions when a person notes a flash and thunderclap substantially simultaneously, (and this happens to the average individual several times a season), this means a lightning flash within one or two hundred feet, since sound travels about 1000 ft. per second. Yet it may be years before any notable lightning damage occurs in any one village or town. This clearly means that most discharges are of very limited energy or severity and find some path to ground without leaving any trace, presumably, usually down tree trunks. There is further ample direct evidence that strokes of minor severity do actually occur. It would seem to follow, then, that there is every reason to suppose that transmission lines, extending for many miles and being twenty to fifty feet in the air and usually free of the protection of trees, will be actually struck occasionally by these low-power strokes, which, while of low power so far as the ability to do conspicuous damage is concerned, are of sufficiently high voltage to flash over insulators.

This view is strongly supported by the evidence of the record of lightning disturbances on the Taylors Falls line* where many insulators were shattered without power on the line, and some poles were splintered, a condition which could hardly be caused by any charges induced on line conductors.

Considering the use of overhead ground wires as a means of protection, we have the following considerations to indicate some material practicable limitations. in the effectiveness of overhead ground wires. Consider a transmission line with ground wire protection just the moment before the discharge of the cloud by a lightning stroke. A considerable bound charge has been drawn to the surface of all the conductors and of the ground wires but the potentials are normal. The instant the cloud is discharged, these bound charges raise the potential of all the wires, conductors and ground wires alike to appropriate voltages which may be very high. So far, the presence of the ground wire is no relief to the voltage on the conductor. But the charge on the ground wire is free to run to earth through the tower, which it does; and *when the potential of the ground wire has fallen toward earth potential* sufficiently, it establishes a static capacity to the line conductors, and this tends to reduce the potential produced by the original bound charge. This might be of very material benefit, except that in all probability, (at least with long span construction), the time required to empty the charge on the ground wire through the tower into the ground through whatever ground resistance may exist, is enough to give the charges on the conductors time to flash over, if they are at sufficiently high voltage to do so.

Of course, the presence of the ground wire tends to reduce the original bound charge on the conductors, since the flux from the ground wire must traverse much of the same path as the flux from the conductors, but the numerical relations are such that at least with six conductors and one ground wire, the effect of the seventh wire must be almost negligible.

However, broadly speaking, from the point of view of absolute continuity of service, since it must be admitted that occasional failures due to one cause or

*Reference. Three papers. A. I. E. E. TRANSACTIONS, Vol. XXVII, Part 1, 1908, By J. F. Vaughan, pp. 397, N. J. Neall, pp. 421, P. H. Thomas, pp. 755. A review of these three papers treating this remarkable set of records will be well worth while to a person interested in the attack of lightning on transmission lines.

another must occur on any line, the use of independent lines, double circuit or single circuit as may be most suitable, running by separate routes would seem to be the only way of getting continuous service.

PERCY H. THOMAS

Some Leaders of the A. I. E. E.

Lewis Buckley Stillwell, the twenty-second president of the American Institute of Electrical Engineers, was born in Scranton, Penn., March 12, 1863. He prepared for college at the Scranton High School; matriculated at Wesleyan University in the class of 1886; transferred to Lehigh University at the end of his sophomore year and completed the course in Electrical Engineering at that institution in 1885, following this by special work in mechanical engineering during the next academic year.

In October, 1886, he entered the employ of the Westinghouse Electric Company at Pittsburgh, and before the end of that year became Assistant Electrician of the company, which position he retained for about five years. During this period, he was actively associated with George Westinghouse, O. B. Shallenberger, William Stanley, Albert Schmid, Nikola Tesla, Charles F. Scott and others, in the rapid development of the alternating current system.

In 1889 and 1890, he was sent to Europe as technical adviser to the British Westinghouse Company and traveled extensively in Great Britain and on the continent, investigating the development of alternating current and other electric systems.

In 1890, while in London, he first met Mr. Edward D. Adams, President of the Cataract Construction Co., and Dr. Coleman Sellers, its Chief Engineer, who were investigating the problem of power development and distribution at Niagara Falls, and from that time until the adoption of the polyphase system and award of the initial Niagara contract to his company, his attention was closely concentrated upon the development of electrical machinery for power transmission.

As Electrical Engineer of the Westinghouse Company, he installed the first three 5000-horse power units at Niagara.

Resigning from the Westinghouse Company and occepting appointment as Electrical Director of the Niagara Falls Power Co., he removed his residence to NiagaraFalls, *and* devoted three years to the extension and completion of power plant No. 1, with local distribution and transmission to Buffalo. During this period, he assumed responsibility for the operation of the plant as well as for the electrical engineering incident to its increase from the original three 5000-horse power units to eleven units.

While at Niagara, he invented and patented the first time-limit circuit-breaker and the diagrammatic switchboard control, these inventions together with the induction regulator, patented in 1888, being among the most important inventions upon which the successful transmission and distribution of alternating-current power has since depended.

In 1899, while still at Niagara, he was appointed by the Manhattan Railway Company Consulting Electrical Engineer, and in that capacity had charge of the electrification of the elevated railways in Manhattan and the Bronx. For something over a year, he divided his time between Niagara Falls and New York City, and, in September, 1900, the first power house unit at Niagara having been completed, and the commercial success of transmission to Buffalo having been demonstrated, tendered his resignation as Electrical Director of the Niagara Companies and established his office as Consulting Engineer in New York.

In 1900, he was appointed Electrical Director of the Rapid Transit Subway Construction Co., and during the next eight years directed the electrification of the New York subways.

In addition to the electrification of the elevated and subway lines in New York, some of his more important professional engagements included consulting engineer for the following:

Consulting Engineer, Hudson Companies, in charge of electrical, mechanical and rolling stock equipment, 1905-1913. Member, Erie Railroad Electric Commission, 1906; United Railways & Electric Co., Baltimore; Interborough Rapid Transit Company; N. Y., New Haven & Hartford R. R. Co., (Hoosac Tunnel Electrification); N. Y., Westchester & Boston Railway Co.; Lehigh Navigation Electric Co., N.Y.; Municipal Railway Corporation; N. Y. State Bridge & Tunnel Commission; and N. J. Interstate Bridge & Tunnel Commission. He was also a Member of the Board of Economics & Engineering, National Association of Owners of Railroad Securities, 1921-1922.

As Consulting Engineer to the Lehigh Navigation Electric Company, in cooperation with his associates, M. G. Starrett, John Van Vleck and the late H. S Putnam, he designed and supervised the construction of the initial 45,000-kw. power plant at Hauto, Penn., with its distribution system—the first large power plant erected in America at the "mouth of the mine."

During the war, he served as a member of the National Research Council.

Mr. Stillwell is a Fellow of the American Institute of Electrical Engineers, Past-President of the American Institute of Consulting Engineers (two terms), member of the National Academy of Sciences, the American Society of Civil Engineers and of the British Institution of Electrical Engineers.

He is a Life Trustee of Princeton University, and for three years served as a member of the Board of Directors of the United States Chamber of Commerce—the only man elected to that body to represent the engineering profession.

Theory of the Autovalve Arrester

BY JOSEPH SLEPIAN[1]

Member, A. I. E. E.

***Synopsis.**—The advantage of valve type arresters for high-voltage, power-system protection is briefly discussed. The theory of the autovalve arrester is given.*

I. Induction and Regulation of Surges

In the last few years, considerable light has been shed on the manner of induction of high voltage on power systems by lightning,[2] and some estimates of the magnitudes involved have been made. Charges on clouds produce electrostatic fields extending down to the ground, which induce charges on power lines. The vertical gradient at the earth's surface due to these fields has been estimated[3] to be of the order of 100 kv. per ft. When the inducing charges on the clouds disappear suddenly by a lightning discharge, the induced charges on the power lines produce voltages to ground equal to the height of the lines multiplied by the inducing gradient, and, therefore, of the order of hundreds of kilovolts. The induced charges may be a few miles in extent.[4]

The power line becomes then a source of voltage, so high as to be dangerous to connected machines, and the very important question arises when considering the possibility of relief by lightning arresters as to what is the regulation of this source of voltage. It is now well recognized[5] that voltage due to a free charge of this type on a power line regulates like a generator having an internal resistance of a few hundred ohms. Hence the voltage can be quickly materially reduced if, and only if, sufficient current is drawn from the line. An arrester will be effective, if, and only if, it draws nearly two amperes per kilovolt of induced surge[6]. An arrester then must be able to discharge hundreds of amperes with only a moderate rise of voltage.

II. Energetics of Surge Dissipation

The large current which must pass through an arrester if it is to be really effective introduces great difficulties in the design of arresters of the arc-resistance type for higher voltage circuits. This is not due to the energy of the surge itself, which is only moderate in amount because of its short duration, but to the energy supplied by the normal working voltage, which lasts throughout the whole arcing period, and may be from one-half cycle to several seconds. For example, a surge 1.86 mi. long, will discharge for only 1/100,000 sec. If an arrester connected to a line, the normal voltage of which to ground is 10,000 volts, discharges 900 amperes from this surge and reduces the voltage thereby to 30,000 volts, the energy involved will be only 30,000 by 900 by 1/100,000, or 280 watt-seconds. On the other hand, if the normal line voltage discharges 300 amperes for one half cycle, or 0.0083 second, the energy will be 10,000 by 300 by 0.0083 or 24,900 watt-seconds, or more than 90 times the energy due to the surge alone.

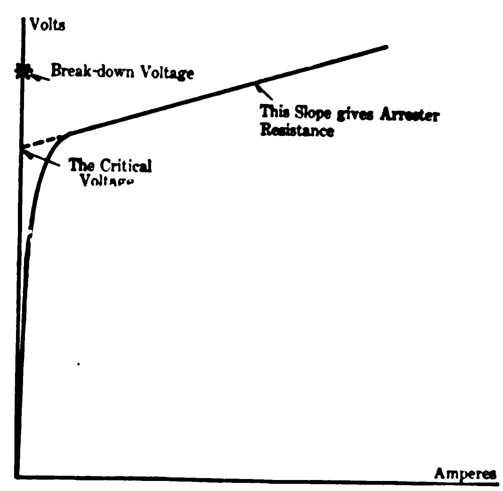

Fig. 1—The Valve Characteristic

Valve type arresters, being built up of elements having the characteristic shown in Fig. 1, are not subject to the disadvantage of disposing of this large draft of energy from the normal voltage. With the passing of the surge, and the restoring of normal voltage, the discharge ceases. It is, therefore, entirely practical to construct valve type arresters with adequate discharge capacity for even the highest voltages.

Some illuminating calculations made for an arrester set at the center of a freed charge as shown in Fig. 2 are given in the curves of Fig. 3. The initial surge voltage is taken as 250 kv. The normal voltage to

ground is taken to be 8660 volts, and the line surge impedance, 400 ohms. The heavy line curves show the reduction in voltage for varying resistance in an arrester of the arc type and one of the valve type with critical voltage, 10,000 volts. Evidently suitable protection is not obtained until the arrester resistance is less than 50 ohms.

The light lines show the energy dissipated in the arrester. In order to get the curve for the valve type well into the picture, it is necessary to consider a surge 400 mi. long; the more reasonable surge length, 4 mi. would be barely visible on the scale chosen.

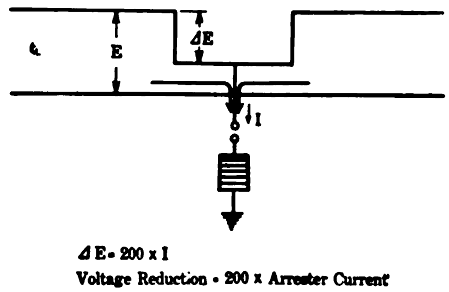

Fig. 2—Basis of Calculation of Fig. 3

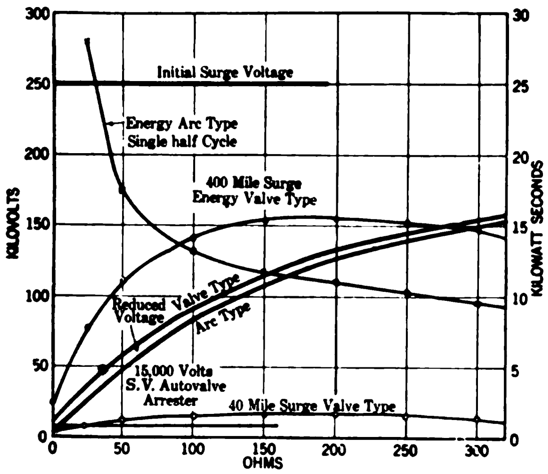

Fig. 3—Energetics of Surge Dissipation

The energy relations illustrated in Fig. 3 have proven determining factors. The only practical arresters with adequate discharge capacity for high-voltage lines are the valve type arresters.

III. Modern Valve Types

The so-called valve characteristic, shown in Fig. 1, has been frequently discussed, and the terminology indicated in the figure is generally used. Conducting systems having this characteristic are numerous in nature. However, in most of these systems the critical voltage is too low (as in contacts or electrolytic polarization cells) or the current which may be carried is too small, (as in thermionic or low-pressure gas tubes), to be useful for lightning arresters for power lines. So far the only systems which have been found to possess the valve characteristic to a necessary degree have been certain films which are made conducting by application of sufficient voltage, but which are subject to constant repair action, requiring the continued application of the high voltage for the maintenance of the conductivity and in which the original resistivity is restored when the voltage is reduced. Three practically used arresters have been developed utilizing films of this type.

The Electrolytic Arrester. The film in this arrester consists of a layer of gas-laden, aluminum oxide, which forms on an aluminum anode in a suitable electrolyte. Application of a few hundred volts breaks this film down, but the flow of current brings about a repairing electrolytic action.

The Oxide Film Arrester. In this arrester, the film is initially a layer of varnish, which, in use, is gradually replaced by litharge, PbO. The repairing action lies in the thermal effect of the current upon lead peroxide, which reduces it to litharge at the points of breakdown of the film.

The Autovalve Arrester. Here the film is a thin layer

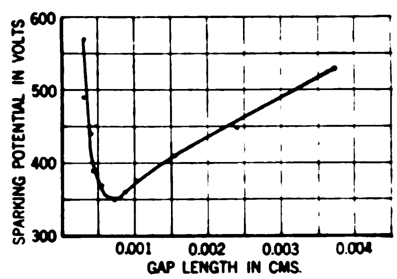

Fig. 4—Sparking Potential for Short Air-Gaps

of air next to a cold cathode which is the seat of the cathode drop in a glow discharge. With the application of sufficient voltage, this air film becomes highly ionized, but the discharge of these ions into the electrodes and recombination quickly restore the normal resistivity when the voltage is reduced.

IV. The Breakdown of Air Between Parallel Plane Electrodes

Since the active element in the autovalve arrester is air, any explanation of the arrester's design and functioning must include a discussion of the properties of air with respect to electrical breakdown and resulting conductivity. Fig. 4 shows the relation between breakdown voltage and distance between parallel plane electrodes. A striking feature of this curve is the minimum at electrode separation of 0.001 cm., so that shorter separation than this requires increased voltage for breakdown. This remarkable fact is readily explained by the current theory of ionization by collision[7].

7. J. J. Thomson, "Conduction of Electricity in Gases," p. 381 J. S. Townsend, "Electricity in Gases," Chap. VIII and IX.

The existence of a minimum breakdown potential of about 350 volts for short gaps may seem contradictory to experience. For example, a widely used type of telephone protector consisting of two small carbon blocks separated by 0.002 in. will usually break down at 200 volts, or sometimes even less. In this case, however, the breakdown is due to the lining up of carbon dust particles in the intense electric field so that a conducting bridge which starts an arc is formed. If precautions are taken to prevent contacts taking place in this or any other manner, the existence of a minimum breakdown voltage may be shown experimentally.

In the autovalve arrester, as will be explained later, it is necessary to use gaps between resistance material electrodes with a breakdown voltage of little more than 350 volts. The curve of Fig. 4 indicates that an electrode separation of 0.0003 in. is necessary for this. At first sight, so minute an electrode separation would appear impracticable in a commercial arrester.

This difficulty was overcome in the early experimental autovalve arresters by merely placing the resistance electrode disks in contact. Due to the resistivity of the electrode material, the gap would not be short-circuited at the contacts. At the same time,

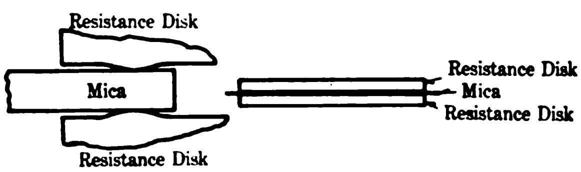

Fig. 5—The Autovalve Gap

in the neighborhood of each contact, there would be points at which the electrode separation was 0.0003 in., and there, breakdown at 350 volts would occur.

A better solution now used was found later and consists in using a mica spacer, 0.003 to 0.005 in. thick, placed directly between the disks. Fig. 5 shows the standard autovalve element (right) and section at the mica spacer, highly magnified (left). The mica, having a dielectric constant of six to seven, distorts the electrostatic field, very much as if it were conducting. Thus there is a concentration of electrostatic stress at the corners of the mica. Due to inherent variations in the nature of the surface of the resistance disk and its contact with the mica spacer, the total voltage applied is not expended symmetrically between the two disks and the edges of the mica, but at some points nearby, all the voltage appears between one resistance disk and the adjacent mica edge, and at other points between the other resistance disk and adjacent edge. Hence, when a little more than 350 volts is applied, these highly stressed points break down and precipitate the discharge of the whole gap. Numerous tests have shown that in commercial autovalve arresters, the breakdown of the column of disks is less than 400 volts per gap.

This expedient of using the electrostatic influence of the mica spacer to precipitate the discharge at low voltage is not practically useful if metal electrodes are used. The discharge must start at the mica, and if it is permitted to concentrate at its point of origin, as with metal electrodes, the mica is quickly destroyed. In the autovalve arrester relatively high resistivity electrodes are used, which limit the intensity of the discharge next to the mica. Hence, thousands of discharges may be sent through it with no deterioration of the mica.

V. Electric Discharges in Air

Arc Discharge. The breakdown of a gap is due to the ionization produced by the high electrostatic gradient.

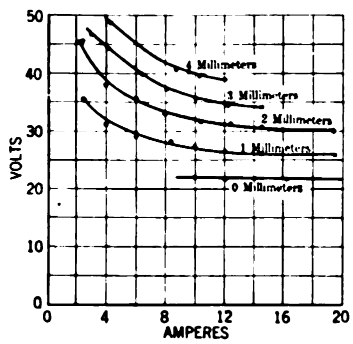

Fig. 6—Arc Characteristics for Copper

If the gap is to remain conducting for the duration of a discharge, this ionization must somehow be maintained. If the cathode remains cold the ionization is effected by the field becoming so distorted that with carbon electrodes approximately 350 volts are impressed across a layer of air 0.001 cm. thick next to the cathode. The discharge then takes the form of a glow. If, however, the cathode becomes sufficiently hot for thermionic emission, much less voltage need be expended at the cathode and the discharge takes the form of an arc.

In the arc discharge the voltage expended at the

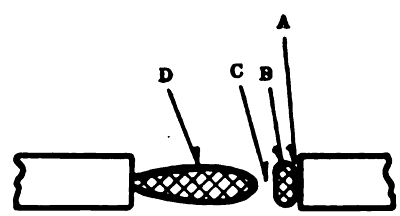

Fig. 7—The Glow Discharge (magnified)

cathode must be sufficiently great to maintain the cathode at a temperature sufficiently high for thermionic emission, and also must be sufficiently great, and concentrated on a sufficiently small space next to the cathode, so that the electrons liberated thermionically will ionize by collision. Twenty volts is sufficient for both these purposes for most electrode materials.

In addition to the voltage expended at the cathode some must be expended in carrying current in the remainder of the discharge. This additional voltage is found to vary inversely as the current strength, so that characteristics such as shown in Fig. 6 are obtained.

It is now clear why an arc discharge is not suitable for giving the valve characteristic to a gap. Aside from the melting or burning of the cathode due to its necessary high temperature the voltage of the arc discharge is too low, (about 20 volts for short gaps) in comparison with the lowest reliable gap breakdown of about 350 volts.

Glow Discharge. When the cathode is too cold for thermionic emission the glow form of discharge takes place in which the ionization is primarily produced by ionization through collision due to high gradient in a film of air about 0.001 cm. thick next to the cathode. The voltage expended in this film is about 350 volts for carbon electrodes. Fig. 7 shows on a magnified scale the appearance of such a glow between copper electrodes. This was obtained by reducing the current to a few milliamperes by means of a high series resistance. When the current is so small, the heating of the cathode is insufficient for an arc, and so the glow discharge may be maintained indefinitely. *A*, the cathode dark space, is the 0.0003-in. film which is kept broken down by the high gradient due to the 300 volts (cathode drop for copper) across it; *B*, the cathode glow is a highly ionized blue region, about 0.005 in. thick. *C*, the Faraday dark space, is also highly conducting, and is about 0.010 in. thick. *D*, the pink positive column, extends to the anode.

So long as the cathode is not completely covered by the discharge, the cathode drop and the cathode current density are approximately independent of current, the cathode glow simply increasing or decreasing in area as the current is varied. The cathode drop and current density do vary with the nature of the cathode; for carbon, the cathode drop and current density are respectively about 350 volts, and 10 amperes per cm^2.

When the cathode is completely covered by glow, further increase of current must of course increase the current density. An increase of current density causes a moderate increase in the cathode drop. Extrapolation of a theoretical formula shows that an increase in current density of 25 amperes per sq. cm. increases the cathode drop by 37½ volts.

The conductivity of the blue glow and the Faraday dark space is so great that little voltage is consumed in these parts. In the pink column, however, the resistivity is greater, and for small currents, the gradient in it may amount to over 5000 volts per cm. However, this gradient decreases, as the current increases.

Volt-ampere characteristics of a glow between copper electrodes are shown in Fig. 8. The longer gap lengths show a falling characteristic due to the properties of the pink positive column. For the 0.1 mm. gap, the positive column is completely eliminated and so, a flat characteristic is obtained.

Transition from Glow to Arc Following Sparkover. At the moment a spark-gap is broken down by high voltage, the electrodes and, in particular, the cathode are, of course, cold. It follows, then, that the discharge must begin as a glow. After a short but finite time, the energy input at the cathode, due to the glow, heats some spot to such a degree that thermionic emission begins there. The cathode drop then falls to about 20 volts and the current concentrates at the point to sufficient degree to maintain the point hot. For a definite time, then, immediately following a sparkover, the discharge is in the form of a glow.

Heating of Autovalve Disk. It would seem, then, that if the time taken between the sparkover of a gap and the transition from the resulting glow into an arc is long compared to the duration of a surge, it should be very easy to make a lightning arrester which would only discharge in glow form. It is easy to get an estimate of the time involved. The formula given on page 98 of "Mathematical Theory of Heat Conduction,"

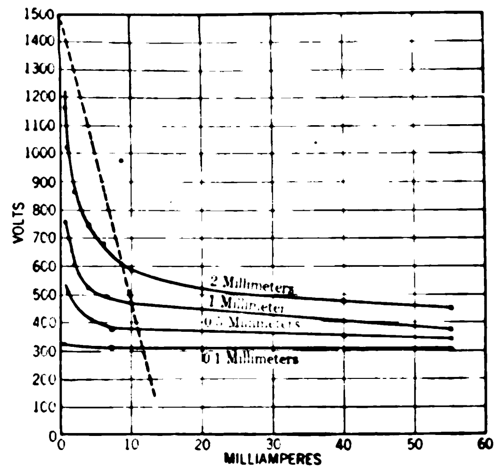

Fig. 8—Glow Characteristics for Copper

Ingersoll and Zobel, Ginn & Co., may be readily transformed into

$$T = \frac{W}{4.18 \sqrt{k\,c\,\delta}}$$

where k, c and δ are heat conductivity, heat capacity and density, respectively of the material making up an infinite solid; W is the power input per unit area on an infinite plane surface in that solid, and T is temperature rise at that surface. Units are deg. cent., small calories, grams, centimeters and watts.

For the resistance material electrodes used in the autovalve arrester, $c = 0.185$ cal. per gr., $k = 0.016$ cal. per cm^2. per deg. cent. per cm^3. $\delta = 2.0$ gr. per cm^3. For a glow discharge at normal current density we have approximately 10 amperes per cm^2. at 350 volts, giving $W = 3500$. Using these numerical values, we get the curves shown in Fig. 9. Remembering that each one-thousandth of a second corresponds to 186 miles of surge, it is evident that the heating of the electrode surface is so slow that in any surge of practical length the temperature rise will be only a few degrees; hence the discharge will still be in the glow form when the surge has ended, and if the normal line voltage per

disk is less than glow voltage, the discharge will stop when the surge voltage disappears.

Current Concentration at Inhomogeneities. So far, it would appear from the formula for the surface temperature rise under a glow that the most desirable materials for electrodes would be those having the highest thermal conductivity and capacity. Metals, then would seem to be particularly suitable, and one would expect to find them superior to the resistance material used in autovalve arresters. However, when put to test contrary results are obtained. With metal electrodes, a heavy discharge only ten microseconds long, will usually end as an arc, whereas, with autovalve arrester disks, it will still be a glow for a discharge 100 times as long. Some as yet unconsidered factor is playing a part here. This factor is the great current concentration in the glow which takes place at any points of the metal surface which happen to have a lower cathode drop than the rest of the metal surface.

It has been mentioned before that the cathode drop

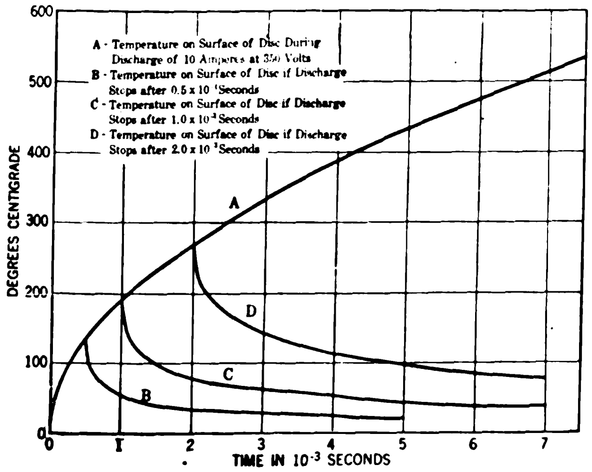

Fig. 9—Temperature Rise of Resistance Material Cathode

in a glow discharge is a function of the material making up the cathode, being 350 volts for carbon, 300 volts for copper, 250 volts for iron, etc. However, like other properties of surfaces, these cathode drops are not absolute constants of the material, but vary somewhat depending upon the state of the surface. Films of absorbed gas or moisture change the cathode drop by a small amount. Dust particles or adhering impurities of any kind may lower the cathode drop enormously. The alkali metals and their oxides are particularly effective in this respect, and may lower the cathode drop to less than 150 volts.

Now imagine on a cathode carrying a glow discharge a point at which the cathode drop is a few volts less than that of the rest of the surface. It is evident that instead of a uniform current distribution over the cathode surface at the moderate density of ten amperes per cm²., there will be concentration of current at the point of low cathode drop. This point will heat up very much faster than is indicated by Fig. 9, and the transition from glow to arc will take place in a much shorter time.

Another effect which is even more important for very short gaps in hastening the transition from glow to arc, is the lining up of minute conducting dust particles, under the intense electrostatic field. In the cathode dark space, the electric gradient is of the order of 350,000 volts per cm. The mechanical force on conducting particles in such fields is relatively enormous, and there is a tendency for these particles to form into chains almost instantly. In very short gaps, five mils or less, these chains bridge the electrodes and start arcs by the current concentration in them with resulting rise in temperature.

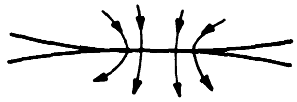

Fig. 10—Current Flow at a Contact

Temperature of a Contact. The effects of surface inhomogeneities and conducting bridges in causing premature heating of some cathode surface point and striking of an arc is combated in the autovalve arrester by giving the electrode material sufficient resistivity. We may say that if at any point less voltage is consumed in the discharge or gap space than at other points, then this difference of voltage will be expended on the resistance of the path offered to current immediately behind this point in the electrode material. Conditions are then very similar to those which take place at a

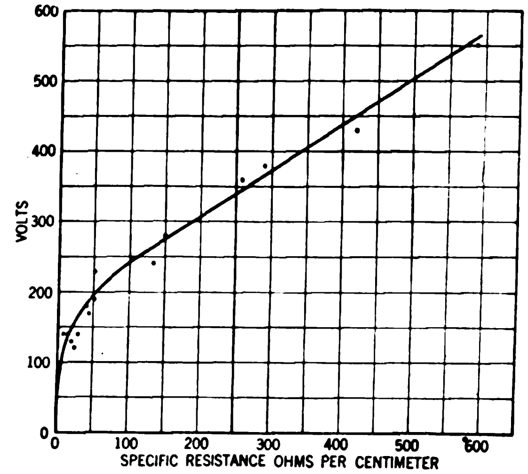

Fig. 11—Voltage to Draw on Arc by Contact

point of contact between electrodes as illustrated diagrammatically in Fig. 10, the arrows indicating the lines of flow of current. It is not difficult to calculate the approximate temperature rise at such a contact, if the contact area is assumed circular. It is

$$T = \frac{E^2}{33\,k\,\rho}$$

where, E is the voltage on the contact, and

k and ρ are the thermal conductivity and electrical resistivity, respectively, of the electrode material. Because of the very small thermal capacity of the

contact, this temperature rise is almost instantaneous. If copper electrodes were used with $k = 1.0$ and $\zeta = 10^{-6}$, a surface inhomogeneity or conducting bridge which would throw 10 volts onto the electrode material at a point would give a temperature rise of

$$T = \frac{100}{33 \times 1 \times 10^{-6}} = 3 \times 10^{6} \text{ deg. cent.,}$$

so that an arc would form instantly. Autovalve electrodes on the other hand with $k = 0.016$ and $\rho = 20$ give

$$T = \frac{100}{33 \times 0.016 \times 20} = 9.4 \text{ deg. cent.,}$$

or a practically negligible increase in the tendency to strike an arc.

Experiments on Arc Drawing at a Contact. The considerations given above show that the voltage necessary to start an arc by contact, increases with the resistivity of the electrode material. The results of experiments confirming this are shown in Fig. 11.

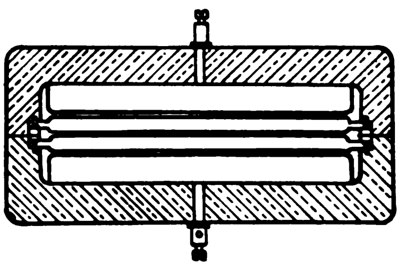

Fig. 12—The Thomas Arrester

The parabolic relation found between voltage and resistivity is predicted by the formula,

$$T = \frac{E^2}{33\, k\, \rho}$$

Design of Autovalve Arrester. The three essential parameters in the autovalve arrester element which determine its electrical performance, are gap length, electrode resistivity, and electrode area. A desirable characteristic is a discharge voltage only little less than the breakdown voltage, and this with a minimum of resistivity in the electrode material so that impractically large area will not be necessary for adequate discharge capacity.

From Fig. 8 it would appear that if the current density is sufficiently limited, a discharge voltage nearly equal to the breakdown voltage may be obtained. Thus the valve characteristic may be obtained for any gap length if only electrodes of sufficiently high resistivity are used. It is very interesting that this principle was understood and described seventeen years ago by P. H. Thomas in his U. S. Patent No. 882,218. Fig. 12 shows his proposed arrester. Quoting from his patent, "It is an essential characteristic of my invention that there shall be an opportunity for a large number of independent static discharges between the discharge plates and that each discharge path shall have such resistance that the dynamo current cannot follow the static discharge."

However, it is only by using very short gaps with a few hundred volts breakdown, that resistivity sufficiently low for a practical arrester may be used. To see this, consider again the curves of Fig. 8 for glow discharge between copper electrodes. Suppose that by using mica spacers or otherwise, a 2-mm. gap could be broken down by 1500 volts. Then the current and voltage of the discharge would be determined by the intersection of the 2-mm. glow curve, and the straight line drawn from 1500 volts on the voltage axis, with a slope equal to the resistance of the circuit. The line shown in the figure corresponds to a resistance of 102,500 ohms, and with this resistance, the discharge voltage is only 600 volts. If the discharge voltage is to be raised up to 20 per cent less than 1500 volts, that is 1200 volts, the line must be swung around until it corresponds to a resistance of 440,000 ohms. At its point of intersection with the 2-mm. glow curve the current will now be one milliampere. Taking 10 amperes per cm². as the current density in the glow this gives 0.001 cm². as the area. The resistance in an electrode up to such an area is given by $\frac{0.261}{a}\rho$ where ρ is the resistivity of the material, a is the radius of the area, in this case 0.0056 cm. Thus, $\rho \times 46.6 = 440{,}000$ or $\rho = 9400$ ohms per cm³. This is prohibitively large. If, however, the gap length and breakdown voltage are lessened, the resistance necessary to keep the discharge voltage nearly equal to the breakdown voltage decreases, and when 0.1-mm. gap with 350-volt breakdown is reached, no resistance is necessary for keeping up the discharge voltage.

For a practical arrester, then, it is necessary to use a gap so short that its glow volt ampere curve is substantially flat. This will occur if the glow has no positive column and from the dimensions given in connection with Fig. 18, this means a gap length not over 0.015 inch. In the commercial autovalve arrester, gap length of not over 0.005 inch is used to ensure breakdown at little more than 350 volts.

With gap lengths less than 0.015 inch the resistivity of the electrode material must be made only high enough to take care of surface inhomogeneities and the partial contacts due to bridging particles. These are not calculable, and the permissible low limit resistivity must be determined by test. The low limit for resistivity in commercial autovalve arresters at present is 20 ohms per cm³., giving a total resistance of only a fraction of an ohm per disk.

The gap length and resistivity being thus given, the area of the electrodes will determine the discharge rate of the arrester. In the *S V* type of autovalve arrester the area has been chosen to give a discharge rate equal to that of the electrolytic arrester.

Carrying Capacity of 60-Cycle Busses for Heavy Currents

BY TITUS G. LE CLAIR[1]

Associate, A. I. E. E.

Synopsis.—*Up to the present time it has seldom been necessary to design busses for carrying capacity above 2000 or 3000 amperes. Within the last few years we have passed this mark, and we shall soon be required to design busses for very much larger capacities.*

For simple geometrical designs there are formulas from which we may calculate the capacities of large busses. These simple designs cannot be easily mounted, and for this reason we must resort to styles which are easier to construct. These types cannot be calculated readily by the mathematics available to the ordinary engineer. This paper is presented with the idea of giving a ready reference for determining bus capacities without involved calculations.

Curves are given showing the carrying capacity of a few types which are proposed as standards, and, in addition, a few curves compiled from tests showing the distribution of current in busses to show the necessity of this type of design. By a little careful study of these curves, the average designer may quickly choose the type of bus which will best meet his requirements for carrying capacity and allowable space. All busses are designed on the basis of 30 deg. cent. temperature rise, and their ratings may be proportionately increased if the conditions warrant a 40 deg. temperature rise.

As the usefulness of electric power becomes more and more widespread and its uses more diversified, large blocks of power are frequently required in a small space. This is especially true in factories where there may be a great many machines on a small floor area with individual motor-drive, or for electric furnace work. In consequence, we find it necessary to supply large blocks of power at low voltage, with correspondingly heavy currents.

As the transmission system grows in size the energy of short circuit on the high-tension system is so great that the cost of protective apparatus, as well as the expense of insulating for high voltage, requires that all power be supplied from large, well protected transformer banks in fire-proof vaults. This means that very heavy currents must be brought out from the transformer bank to the distribution switchboard or to the furnace through a single low-tension bus. Due to this rapid development it has become necessary within the last few years to design busses far beyond the old limits of 2000- or 3000-ampere capacity, with the time not far in the future when we shall need to carry 10,000 amperes or more on a single low-tension bus.

Theory

In any d-c. circuit, be the conductor solid, laminated or stranded, the current divides in all parts in proportion to the resistance, which means that with a conductor of homogeneous material, the current is practically the same in all parts. The same condition does not hold true, however, for alternating current. In addition to the resistance drop, an alternating current introduces an alternating flux surrounding any element of the conductor. This alternating flux generates a voltage which tends to oppose the flow of current in the conductor element. When we consider a large conductor, it is obvious that the lines of force caused by an element in the outer part surround the entire conductor, but, for a central element, some of the flux does not cut the outer element. The result is that the effective impedance of an element in the central part of the copper is higher than in the outer edge, thereby forcing most of the current to the outer surface, producing the so-called skin effect. In very large conductors this can be carried so far as to have the current in the center of the bus very nearly in the opposite direction to the current in the outer part of the bus, as well as being smaller in magnitude.

When the phases are placed close together there is, in addition to the skin effect, a voltage induced by the flux from an opposite phase which is not uniform over the entire conductor and forces current toward the near side. This is called the proximity effect. Both the skin effect[2] and proximity effect[3] can be calculated for cylindrical or tubular conductors from formulas developed by H. B. Dwight.

Unfortunately, it does not often pay, due to the difficulty of mounting and of making connections, as a practical problem to use a circular conductor for very large bus work. Former practise has been to build the bus of laminated copper bars for the required capacity. For a bus of this shape, it is impracticable, if not utterly impossible, to calculate the distribution of current in order to obtain the losses and temperature rise on alternating current circuits. To further complicate the problem nearly all high capacity busses are three-phase and not single-phase, which makes it more difficult.

Tests

Due to the demand for large increases in bus capacity and the impossibility of making calculations, we have just completed a series of tests to determine, if possible, an efficient and practicable type of bus construction for very high currents.

3. *Skin effect and Proximity Effect in Tubular Conductors*, H. B. Dwight, JOURNAL A. I. E. E., Vol. XLI, p. 189.

In order to make these tests applicable to heavy currents and three-phase circuits, a three-phase bus, 20 ft. long was set up and connected in the circuit between the transformer and three of the rings of a 3900-kw., 230-volt, rotary converter. (See Fig. 1.) This converter could be operated in parallel with another machine on the d-c. side and permitted a ready control of the current up to quite high values. Practically all tests were run with constant current to determine the ultimate temperature rise of the various types of bus construction.

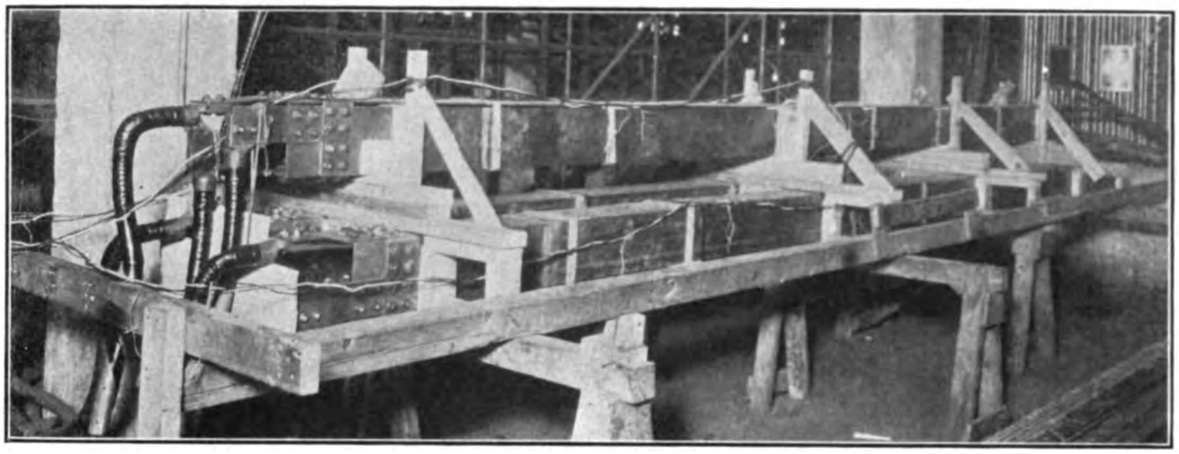

FIG. 1—TEST BUS

Consisting of four 8-in. by ¼-in. copper bars per phase, arranged in rectangular form. Phases on corners of an equilateral triangle, 17-in. sides.

Temperature measurements were made by means of thermocouples connected to the centers of the various bars in this 20-ft. section. A number of checks were made during the progress of the test with temperature measurements at points other than the center of the bus to be sure that no contact resistance or other variables were affecting the results. Impedance voltage drop was measured by means of straight leads perpendicular to the bus, carried far enough away to be out of the influence of the magnetic circuit.

In addition to these measurements, the current in various parts of individual conductors was also determined by a method similar to that described by C. F. Wagner.[4] The leads described running parallel to the bars, were No. 24 enameled wire. In order to be positive that there was no space between the wire and the bus surface and no sag, this wire was cemented to the surface of the copper with asbestos cement. To eliminate end effects, only the central 15 ft. of bus were used. In the lower right-hand corner of Fig. 1 may be seen a four-inch bar with five leads cemented on.

We have found a number of things which enter into the construction of a bus that are not constant for all circuits. For example, the current distribution will be very different on single-phase from that on three-phase circuits. Also, there is an extremely great difference between isolated-phase and group-phase busses due to proximity effect.

The majority of engineers are not particularly interested in the exact distribution of current in various parts of the bus. The primary question which enters the designer's mind is rather how much copper he must use and how he may best use it. A concrete example of the distribution of current will, however, clarify ideas of the results of skin effect and proximity effect and help a great deal in deciding for a particular case what form should be used. In Fig. 2 is shown a three-phase bus,

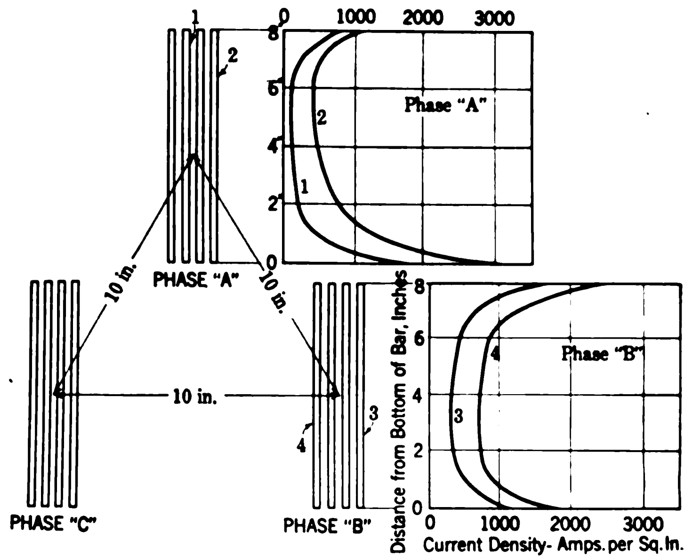

FIG. 2—CURRENT DISTRIBUTION IN A THREE-PHASE BUS

Consisting of four 8-in. by ¼-in. copper bars per phase, at 4000 amperes per phase.

each phase consisting of four 8-in. by ¼-in. bars per phase with phases set in an equilateral triangle on ten-inch centers. It will be noted that the current in A phase bus is practically all in the very bottom edge of the bars, and the usefulness of the upper half of the bar is more in the nature of a radiator than a conductor. For this

4. "Current Distribution in Multi-conductor, Single-Phase Busses," C. F. Wagner, *Electrical World*, March 18, 1922.

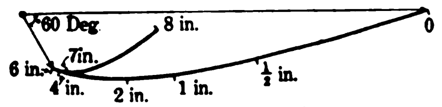

Fig. 3—Polar Diagram of Current Distribution in Outer Surface of 8-In. by ¼-In. Bar

Figures refer to distances from bottom edge of bar The surface considered is the same as Curve 2 in Fig. 2.

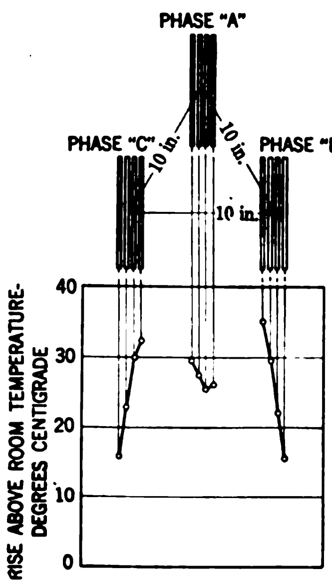

Fig. 4—Temperature Rise on a Three-Phase Bus

reason a bus of similar construction, except made of four-inch bars in the same layout, that is, four bars wide and two bars high, would not be nearly so effective because the upper set of bars would not carry much

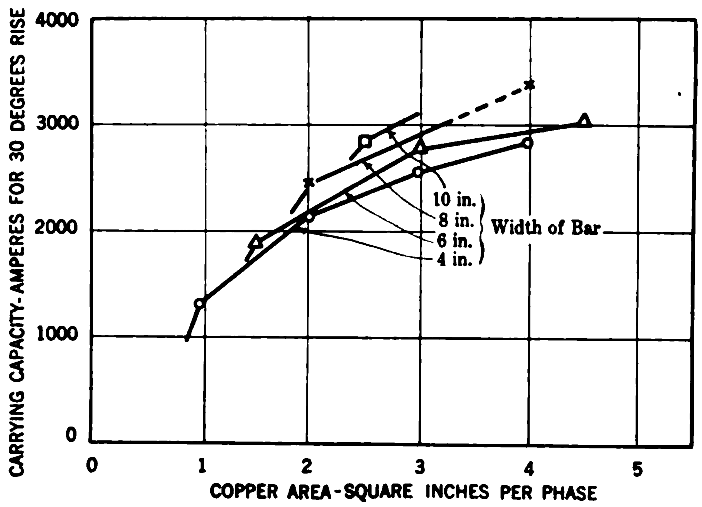

Fig. 5—Electric Power Club Standards

Ratings of laminated busses on grouped phases up to 3000 amperes at 60 cycles. Centers on a straight line with 8 in. between phases; ¼-in. spacing between laminations.

current, and in addition would have poor heat connection to the lower bars. Hence, they would not serve as good radiators.

It may also be interesting to note in Fig. 3 the relation of the phase angle of current in various parts of the bar.

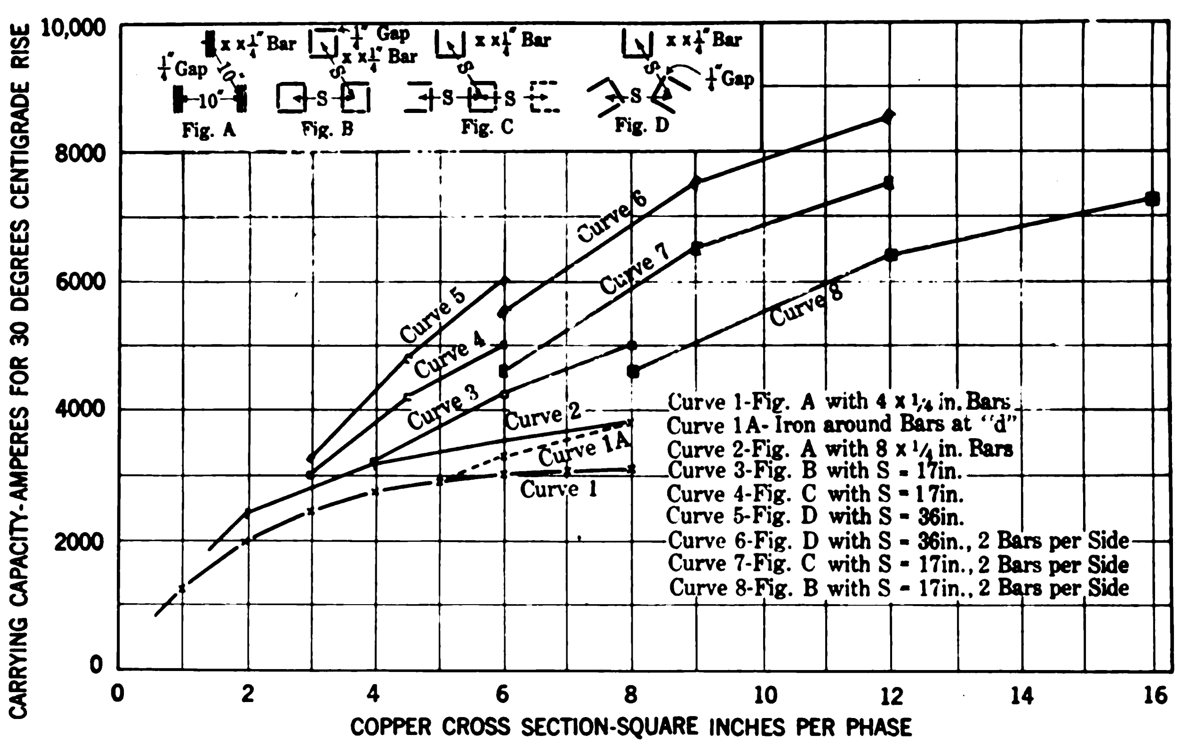

Fig. 6—Ratings of Busses on Grouped Phases Above 3000 Amperes at 60 Cycles

All bars are ¼ in. thick by 4 in., 6 in. or 8 in. wide. For instance, the center point on Curve 6 represents six bars of 6-in. by ¼-in. copper and the upper point on the same curve means six bars of 8-in. by ¼-in. copper.

It will be seen that the current at the minimum point lags 60 deg. behind that in the lower edge and that the point of minimum current is 6 in. instead of 4 in. from the bottom of the bar. As we go nearer to the center of the bus, the current lags further behind that in the outer edge of the outer conductor until we find the current at the center is very nearly 180 deg. out of phase. As a striking example, in a bus consisting of four bars

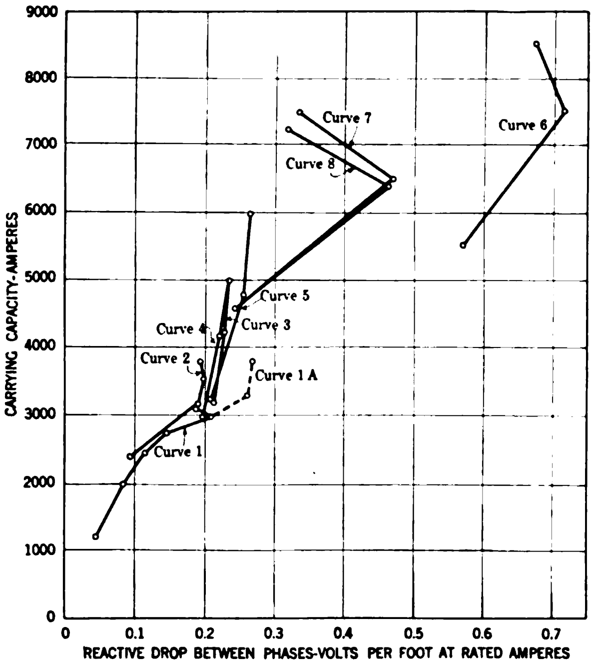

FIG. 7—REACTIVE VOLTAGE DROP ON THREE-PHASE BUSSES

Curve numbers and points refer to corresponding curve numbers and points for busses shown in Fig. 6. With phases arranged with centers on the same straight line, the average drop will be about 25 per cent higher and the drop in the two outer phases will be higher than that in the center phase.

laid on the sides of a rectangle, the addition of a fifth bar in the center actually increased the losses and temperature rise for the same current. In Mr. Wagner's article,[4] for single-phase busses he draws the curve from the outer edge to the center of the bar, and assumes that the same condition holds from the center to the opposite edge of a bar. This is perfectly true in some cases but not at all true in others, and the electrical center, or the point of minimum current in a bar, may not be the physical center.

If we now look at Fig. 4 to get the temperature rises of the various bars and consider that the temperature rise is proportional to the square of the current, we get a somewhat erroneous impression, due to the fact that while the central bars may be carrying some current, this is not a measure of their effectiveness, because as stated before the current in the central bar may be sufficiently out of phase to be of little or no value.

For moderate currents the important item in the design of a bus is the matter of ventilation. When we come to consider very heavy currents, this matter of ventilation is of minor importance, since ventilation is useless if all the current is carried in a small portion of the bus. The prime consideration, then, is to put the copper where it will be most useful.

BUS CAPACITIES

There are very few data available at this time on the carrying capacity of busses for heavy current. For example, some operating companies have for many years used the standard of 1000 amperes per square inch of copper section. This gives ample copper for busses up to 2000 amperes, but beyond this point the rule no longer holds. For isolated phases, the General Electric

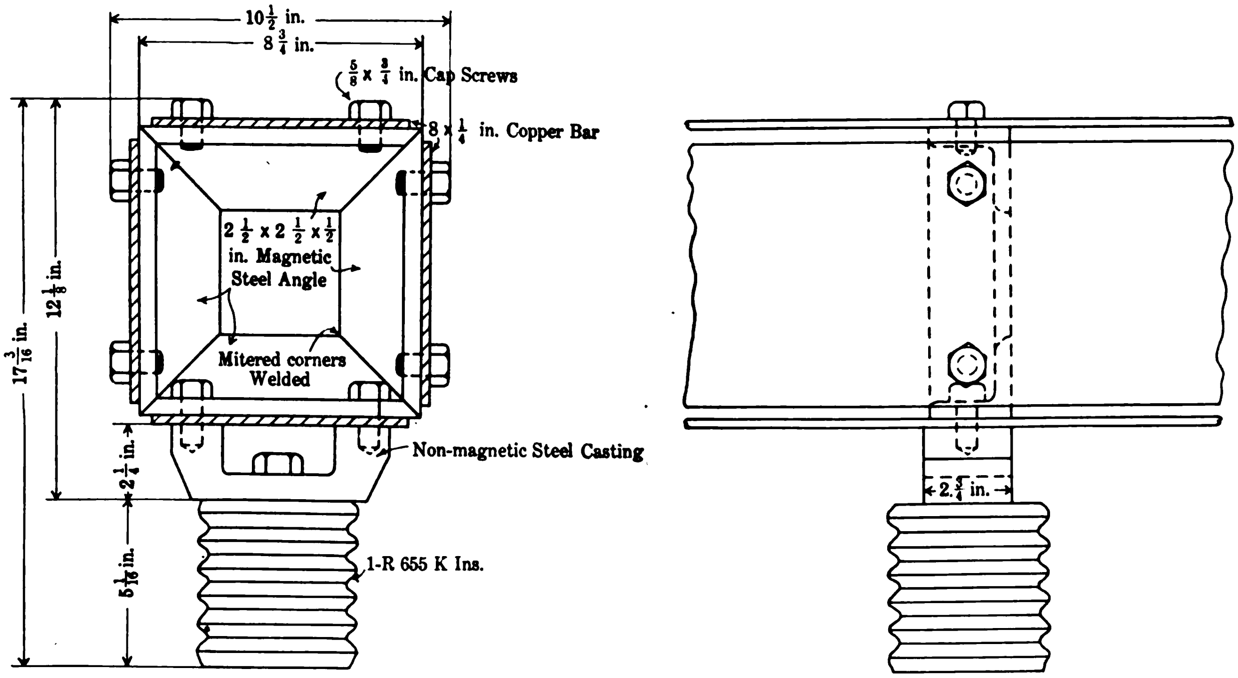

FIG. 8—FORM OF BUS SUPPORT FOR RECTANGULAR BUSSES REQUIRING DRILLING OF COPPER ON JOB. NO CLAMPS REQUIRED

Company has worked out a system of busses[5] which is not at all difficult to mount and is very satisfactory for currents up to 7400 amperes at 60 cycles. Due to the proximity effect as shown in the test data, it is obvious that this type of bus construction would be of little value for group phases on very close centers since the current would all be thrown into one corner of the bus and would cause it to run very hot. The Electric Power Club has given as a standard Fig. 5, which is for group phases up to 3000 amperes. Beyond this point we have compiled from our test data the curves in Fig. 6 for special types of bus construction. The curves do not, of course, give all the data required for any particular installation, but they give the points necessary for determining what should be used.

In Fig. 6, Curve 7 gives the rating of C on 17-in. centers. If the phases are separated further, the ratings of these busses will be raised somewhat but not so high as Curve 6. Curve 6 gives the rating of D on 36-in. centers, and the rating of this bus would be lower on the closer centers but not so low as Curve 7. In Curve 8 the rating may be very materially increased by one or both of two methods, either by a wider opening of the corners of the rectangle, or by further separating the phases. If both these things are done, we may obtain a bus of perhaps higher carrying capacity than that given in Curve 6. When the space limitations or the allowable reactive drop does not demand that phases be on the corners of an equilateral triangle, the dotted arrangement shown in C is practically equivalent in carrying capacity to that of D.

5. *General Electric Bulletin No. 87000-D*, Sept. 1924, p. 26.

Up to about 3000 amperes the reactance of the bus is not of very great importance, but beyond this point and especially for low voltages it becomes quite a serious item. For instance, on a bus carrying 6000 amperes at 230 volts and only 30 ft. long, it may be readily seen from Fig. 7 that the reactive drop may be from 3 per cent to 8 per cent of line voltage. This, in addition to the reactance of feeders, may cause a very poor voltage regulation at low power factors unless care is used in the selection of the bus.

Another important point in the matter of reactance is that it is frequently necessary to parallel transformer banks of different sizes or with different lengths of copper from the banks to the point of paralleling. For large transformers the bus reactance is considerable compared to the transformer reactance and up to the point of paralleling, the bus reactance may be considered a part of the transformer reactance so far as division of load is concerned. This effect is especially noticeable where transformer banks of different capacities are paralleled, because the percentage reactance per foot is very much higher for large than for small busses. Sometimes it even becomes necessary to install a reactance in series with the smaller transformer bank to prevent overheating of one bank when the other is not fully loaded.

In Curve 1-A, Fig. 6, is shown the carrying capacity of a laminated bus, balanced with magnetic steel, as proposed by Mr. Wagner. It is true that the addition of this magnetic steel does increase the carrying capacity. However, the amount of iron to be added must be determined by the cut-and-try method for any in-

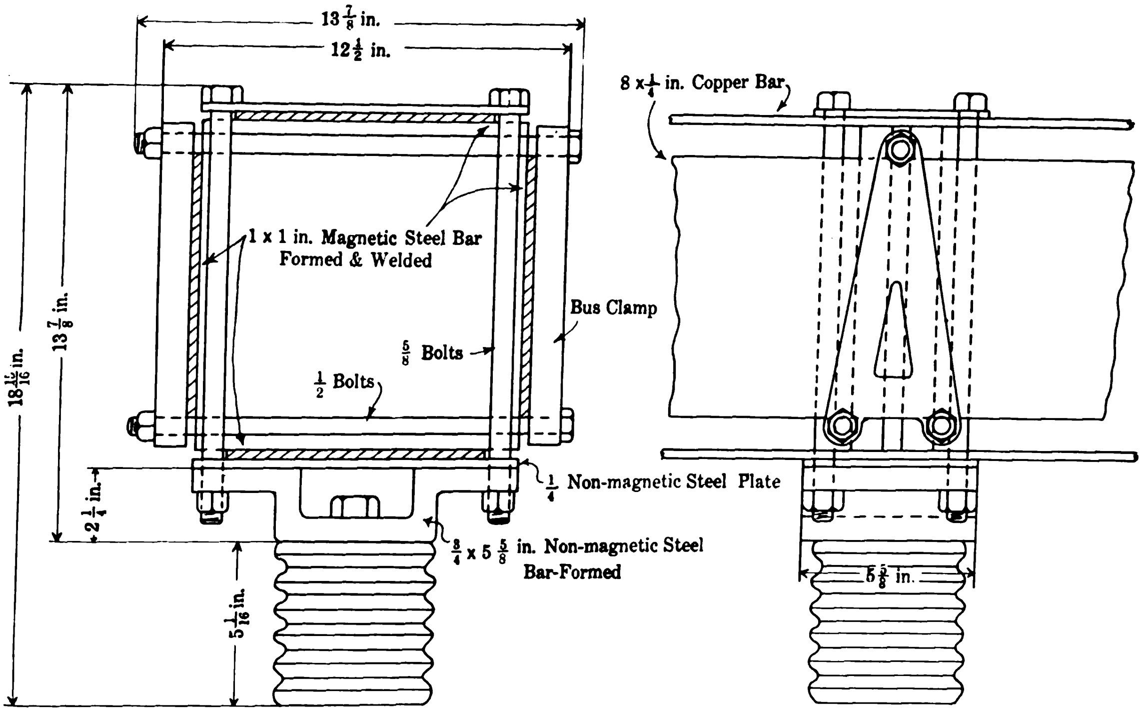

FIG. 9—FORM OF BUS SUPPORT FOR RECTANGULAR BUSSES REQUIRING NO JOB DRILLING OF COPPER

stallation and the cost of adding this balancing becomes prohibitive, especially when the class of labor usually employed knows nothing of what is to be done.

The principal objection to the use of a rectangular form of bus is the same as one of the objections to the tubular form of bus; that is, the difficulty of mounting. However, a little careful consideration will show that the rectangular bus is not particularly difficult to mount since flat clamps may be used which are very similar to those used for an ordinary laminated bus.

The manner of making taps is little more difficult than with the ordinary laminated bus because all the copper surfaces are flat. Especially is this true if the corners of the rectangle are left open, making room to handle bolts inside. The necessary bracing between phases may be attached to the clamps in practically the same way as is done with laminated busses. We have added two preliminary sketches of supports, (Figs. 8 and 9). The type which is cheapest to use depends a good deal upon the type of labor employed. Where skilled and experienced labor is used on the job, Fig. 8 requires less material and would probably be cheapest to install. Where the labor is not particularly skilled or fast, or where labor costs are high, Fig. 9, although it requires more material, takes very little time to mount and would not be as expensive per ampere of current carried as the clamp now used for laminated busses. Neither one of these supports is particularly difficult to handle, nor is it particularly difficult to make taps to this bus since there is room for strap copper or lug connections on the surface of every bar. When these supports are used on the form of bus shown in Fig. 6c, the bar nearest the support may be omitted without changing the method of mounting.

In presenting this paper we have hoped to give a ready reference through which engineers may choose the type of bus best adapted for their needs without any involved calculations which they have neither time nor inclination to make. In conclusion, let us state that although the Electric Power Club Standards call for the maximum of 30 deg. cent. temperature rise and the busses given are designed on this basis, nevertheless, a number of years' experience has shown that a 40-deg. temperature rise gives no trouble due to oxidation when reasonably good connections are made. Especially is this true when the ambient temperature is nearer to 25 deg. than to 40 deg. cent.

Motor Band Losses

BY T. SPOONER[1]

Member, A. I. E. E.

Synopsis.*—It is shown that railway motor band losses are of appreciable magnitude, sometimes sufficiently large to be detrimental to the cooling of the machine. By tests of a small machine checked against those of a large one, the band losses are found to vary according to the 1.7 power of the frequency and from the 1.35 to the 1.8 power of the induction, depending on the width and type of band. These losses are shown to be due chiefly to the change in the radial component of the flux as the band passes by the pole tip. For average bands, about 15 per cent of the losses (hysteresis and eddy) are due to the tangential flux in the bands. A typical set of curves is shown for calculating band losses.*

* * * * *

IN most types of rotating electrical apparatus, the rotor windings are held in position by some sort of slot wedge. However, in the case of d-c. railway motors, it is almost universal practise, (in this country at least), to hold the rotor windings in the slot by means of wire bands. These bands, when over the core material, are placed in shallow slots in the core. They are from ½ in. to ¾ in. wide and are spaced approximately three in. apart. Much wider bands are often used over the end windings but in this paper we shall be concerned only with the bands over the core.

It is often assumed that the band losses are so small as to be negligible; and even if they are not negligible, the heat is readily dissipated, since the bands are on the surface of the rotor. As a matter of fact, band losses are sometimes of quite considerable magnitude and they occur adjacent to the windings, thus preventing loss of heat from the windings and teeth, even though they do not actually transfer heat to these parts. Moreover, the band losses may materially heat the cooling air in the air-gap, thus making it much less effective.

To be presented at the Midwinter Convention of the A. I. E. E., New York, N. Y., February 8-11, 1926.

BAND CONSTRUCTION

There are many kinds of band construction and band materials in use, but here we shall deal with only three or four common types. The steel banding wire for the experiments to be described had a diameter of either 0.0453 in. or 0.0641 in., and a resistivity of about 18.5 microhm-centimeters. The bands were wound on a 0.0125-in. soft iron, tinned strip which, in turn, was insulated from the core by means of a strip of asbestos tape. In order to reduce the band losses, in some cases each band was divided into two sections, each section having its own strip and the two sections insulated from each other. The wires of each band or

section were held together by clips of 0.0125-in. soft iron about ½ in. wide, spaced approximately every three inches. The wires were wound on the armature under considerable tension and the wires, strips and clips were soldered together. The solder was of pure tin, having a resistivity of about 13 microhm-centimeters.

Factors Affecting the Band Losses

The problem of band losses is much more complicated than is evident from a first inspection. So far as the phenomena have been analyzed, the following factors enter into the problem:

a. Width of bands
b. Width of teeth at air-gap
c. Size of band wires
d. Amount of solder used
e. Dimensions of tinned strips and clips
f. Normal resistivity of wire, solder and tinned strips
g. Temperature of bands
h. Frequency
i. Induction
   1. Tooth (radial)
   2. Band (tangential)
j. Field form
k. Air-gap
l. Depth of band groove

If the bands are not insulated from the core, the losses due to the bands may be anywhere from the insulated values to many hundred per cent higher, the values depending on the intimacy of contact between the bands and laminations. The following discussion assumes perfect insulation from the teeth.

There are several types of band loss for a given total armature flux which may be classified as follows:

1. Eddy-current losses in band wires, solder and tinned strip, due to radial flux.
2. Eddy-current losses in band wires, solder and tinned strip due to tangential flux.
3. Normal hysteresis loss in band wires and strip due to tangential flux.
4. Additional hysteresis losses due to displaced hysteresis loops.
5. Additional armature tooth loss (eddy-current) due to the damping out of flux by the bands in the region of the pole tips, thus producing flux across laminations which may result in extra eddy losses.

The eddy-current losses which occur in the bands themselves, due to item 1, (radial flux), are by far the most important, as can be shown by a few simple calculations from data available. The induced voltage in the bands has much the same wave form as given by the familiar case of an exploring coil surrounding a tooth and connected to an oscillograph. It has, in general, two large positive humps, followed by two large negative humps, with many intervening ripples. The large humps are produced when the tooth passes a pole tip and their shape and magnitude are a function of the shape of the pole tips.

The tangential fluxes passing from one pole tip to the next, through the bands, are usually of much higher flux density than the radial fluxes, but due to the small thickness of the bands, the eddy-current losses are small. However, the hysteresis losses correspond to the tangential flux; namely, the maximum induction.

The bands are subjected to an elliptical field and we shall assume that the hysteresis loss is the same as would be produced by the maximum tangential induction acting under alternating flux conditions. This tangential flux is a maximum in the position just before the band passes under the pole tip. It is lower at a position midway between the poles and zero at the center of the pole. This decrease in flux at the mid-point between the poles produces a minor hysteresis loop. Since this loop is greatly displaced from the normal position, there results appreciable increase in the hysteresis losses.

Due to the eddy currents in the bands, caused by the radial flux and the consequent damping out of the flux through the bands, the air-gap flux must tend to pass around the bands, giving decreased relative induction in that portion of the tooth under the bands. These fluxes tend to become uniform again under the bands, thus producing a flux component at right angles to the plane of laminations which may produce appreciable eddy-current losses.

Test Apparatus

The test results to be described were obtained chiefly on a typical small four-pole railway motor direct-coupled to a d-c. shunt motor. Two armatures were provided with the following dimensions:

	Armature A.	Armature B.
Diameter	9 in.	9 in.
Length	7 "	7 "
Number of slots (open)	31	16
Slot width at air-gap	0.370 in.	0.635 in.
Slot pitch at air-gap	0.911 "	1.77 "
Slot depth	1.00 "	1.50 "

The armatures had three band grooves 0.125 in. deep and 0.75 in. wide. The motor was provided with two sets of poles, one normal and the other chamfered 1/16 in. at each tip. The bands consisted of fourteen turns each of 0.0453 in. wire or eight turns each of 0.0641 in. wire. Both single and double bands were used for the larger size of wire. In the case of the double bands, each section had four turns.

Test Methods

Tests were made with three air-gaps; namely, 0.1 in., 0.2 in. and 0.3 in. and three speeds; 600, 1200 and 1800 rev. per min., corresponding to 20, 40 and 60 cycles respectively. Chamfered poles were used with 0.0452 in. and 0.0641 in. bands and 0.1 in. air-gap only.

The d-c. drive motor was supplied by a storage battery. No-load losses were determined with the bare armature for the various air-gaps and for various field excitations. The armature flux-per-pole was determined for various excitations by means of an exploring coil and d-c. voltmeter connected through a synchronous contactor. Corresponding maximum armature tooth inductions were determined ballistically by means of a tooth exploring coil and a ballistic galvanometer. Also the r. m. s. tooth voltages were determined by means of the tooth exploring coil and a Paul dynamometer type voltmeter which had a very small frequency error. From a previous investigation, data were available for the actual tooth-voltage wave forms as obtained by oscillograph.

In order to determine the tangential inductions in the bands the exploring coil was wound on the center band between two teeth. The motor field was reversed and the band inductions obtained ballistically. This was done for various field strengths for the position opposite the center point between the poles and for the position of maximum tangential induction, namely, with the exploring coil a little beyond the tip of the pole. Also a curve was obtained for one field strength and the various air-gaps between tangential band induction and armature position for a rotation of 90 electrical degrees.

Test Results

While the test results are referred to the average tooth-top induction, since this factor probably correlates best with the band losses, it should be remembered that the actual radial band inductions are considerably less and sometimes only about one-half the values corresponding to the average tooth top induction, due to the greater reluctance produced by the band grooves.

Fig. 1 shows some typical curves for tangential band inductions, which inductions are chiefly responsible for the hysteresis losses. The radial flux is, of course, approximately proportional to the tooth-top inductions and has nearly the shape of the field form. Fig. 2 shows some typical band-loss data for armature A, with the armature core, tooth and pole-face losses included for comparison. It will be noted that in one case the tinned strip was omitted from under the band wires.

Fig. 3, plotted on double log paper, shows band-loss calculation curves for a 0.0461-in. insulated band, eight wires wide. This method of plotting makes a very convenient form in which to have the results, since the losses vary approximately exponentially with frequency and induction. From theoretical and somewhat meager test considerations the band losses apparently vary about as the square of the band width. If desired, another curve could be added to Fig. 3, giving a factor to take care of the width.

It was found that the band losses varied only slightly with air-gap for a given armature flux, due probably to the fact that with larger air-gaps, though the radial flux increased, the rate of flux change became less, thus giving a relatively smaller induced band voltage. Also pole chamfering had only a small effect due to the fact that while the maximum individual voltages were less, the maximum tooth inductions were greater for the same total pole flux.

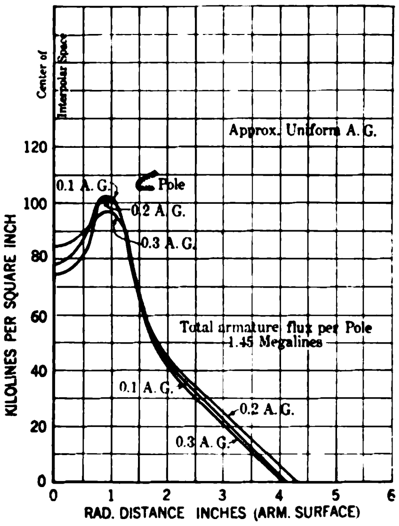

Fig. 1—Tangential Band Inductions—0.0641 Bands

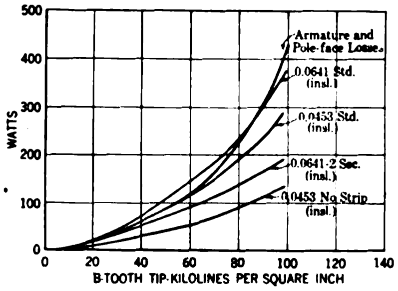

Fig. 2—Band Losses for D-C. Railway-Motor Armature "A" 0.2 Air Gap—1200 Rev. per Min.

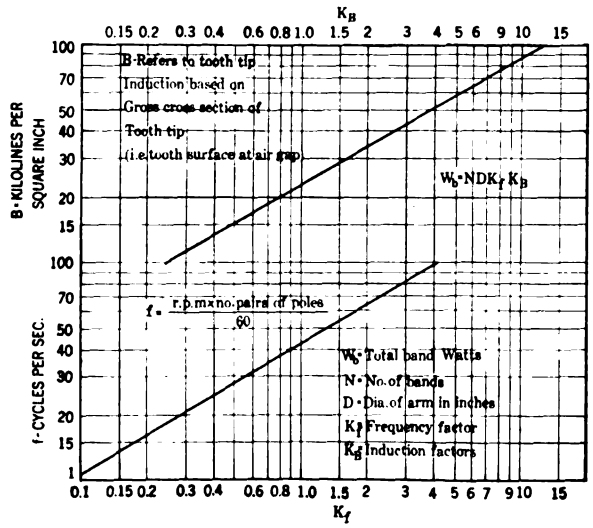

Fig. 3—Band Losses for D-C. Railway-Motor Armature 8-0.0453 in. Diameter Wires— One Sec. Strip

The following table gives the band loss coefficients, tooth-induction and frequency exponents for the *A* armature.

TABLE I
BAND LOSS COEFFICIENTS AND EXPONENTS
Coefficients are for 1200 rev. per min. (40 cycles), 80 kilolines tooth tip induction, and 0.1 in. air-gap.

Band (Diameter of wires-in.)	Coefficient	Exponents Frequency	Tooth Induction	Remarks
0.0453 in.	71	1.71	1.52	No strip
0.0453 in.	230	1.71	1.63	Strip
0.0641 in.	238	1.67	1.73	Strip—one sec.
0.0641 in.	188	1.85	1.87	Strip—ch. poles
0.0641 in.	180	1.68	1.34	Strip—two sec.

The coefficients are the total losses due to the presence of the bands for the specified conditions. There is some variation in exponents and coefficients for various air-gaps and frequencies. The values given are the mean results for the exponents. Tests on a much larger machine gave approximately the same results.

In order to show the relation between the various band losses, the hysteresis losses due to the tangential fluxes were calculated for certain conditions as follows: 0.0641 in. bands (one section), 60 cycles, 80 kilolines/sq. in. tooth-top induction and 0.2 in. air-gap.

Tangential eddy current loss	= 43	watts
Hysteresis loss	= 23	watts
Sum	= 66	watts
Actual test loss	= 470	watts.

This indicates that for these conditions 85 per cent of the loss is due to the radial flux.

It would normally be assumed that wider teeth would produce higher band losses. Tests obtained with the *B* armature, however, having only 16 as against 31 teeth and correspondingly wider tooth tops, gave approximately the same band losses. By means of a ballistic exploration of the tooth-top inductions over the leading and trailing portions of the teeth as they passed by the pole tips, it was found that most of the change in flux as a point on the tooth top passed the pole tip occurred over a distance equal to less than one-half the tangential width of the tooth top for the *B* armature. This means that for these particular poles a tooth top width of from 0.5 to 1 inch or over will give approximately the same band losses. For still narrower teeth there might be considerable difference.

Some tests made on the experimental and other machines show that if the bands are not insulated from the core, very much larger losses than normal will occur. The armature laminations are short circuited on the shaft and the bands touching the laminations at the periphery complete an electrical circuit, which may make a very good path for induced currents. It was found possible to produce losses of several kilowatts in the small 7 x 9 armature by this means. It is possible to apply uninsulated bands without producing these extra losses but only in the case that the slot windings are so thick radially that the bands do not touch the core. In practise, this procedure is not possible and there is a general tendency toward the use of insulating materials even though most of the band tension is carried by the coils.

Discussion of Results and Conclusions

The eddy currents in the bands due to the radial flux which are chiefly responsible for the band losses are undoubtedly of sufficient magnitude to appreciably hinder the change of flux as the band passes under the pole tip. This is analogous to skin effect. It will be noted that at low and moderate inductions, the two-section bands have nearly as much loss as the wide single-section bands, although theoretically the losses for the former should be ¼. This is probably due partly to the fact that the losses for the wide bands are reduced by skin effect at the lower inductions. At the higher inductions, the magnetizing forces become so great that the damping effect of the eddies becomes less important and relatively more radial flux passes through the wide bands, thus giving a higher induction exponent for the wide bands than for the narrow. Again due to these damping currents, flux may pass around the bands under certain conditions, thus altering the eddy-current losses in the teeth by producing flux components at right angles to the tooth laminations. This is purely speculative. These induction exponents are lower than would be expected. It may be that heating of the bands has much to do with it.

The frequency exponents are less than two, due, undoubtedly, partly at least, to the skin effect in the bands.

It has been impracticable so far to derive a theoretical mathematical formula for calculating the band losses caused by the radial component of flux. This is an interesting problem for anyone mathematically inclined. The chief difficulty, even without assuming any damping effects, is to determine the most probable path of the eddy currents in the bands.

Considerable reduction in band losses may be effected by omitting the metal strip under the wires, but this gives less satisfactory construction from a mechanical standpoint. The insulation under the bands can not be dispensed with safely in all cases.

Non-magnetic band wire may be used if desired, but due to its inferior mechanical properties and slight effect on the band losses, its use is probably not justified.

A band wire and a solder of high electrical resistance would be of considerable advantage if they were otherwise suitable.

In large railway motors, the band losses may, under certain conditions, amount to two or three kilowatts and are therefore not negligible. Band temperatures up to 200 deg. cent., or more, may occur. At very high inductions the band temperature may increase so rapidly that the rate of increase of band losses with induction will sometimes decrease very considerably due to the increased resistance of the bands.

A New Edition of A. I. E. E. Standards

BY F. D. NEWBURY[1]

Fellow, A. I. E. E.

Editor's Note. The following article was prepared by Mr. Newbury in July and was first published in the September issue of *The Electric Journal.* It has been revised in some minor respects to bring it up to date and is published here in order to extend the knowledge of the new Institute Standards to a still wider circle of engineers.

THE American Institute of Electrical Engineers is now issuing a new edition of its Standards that involves a complete change in form of publication and many important changes and additions in subject matter. This is an event of importance to the electrical industry and engineers generally should become familiar with these new Standards. The purpose of this brief article is to bring the subject to the attention of engineers and point out some of the major changes that have been made.

Since the first publication of Institute Standards, more than twenty-five years ago, there have been only two other revisions that compare with the present one in scope and importance. In December, 1914, a complete revision was published which had been initiated by the extensive program of papers presented at the first Midwinter Convention in February 1913. This first revision was notable for the new material it introduced: the hot spot principle in determining limiting temperature rises; the classification of insulations according to safe temperature limits; the single 50 deg. rating without overload for rotating machines and the use of the embedded temperature detector method of measuring temperatures in large alternators. This revision definitely extended the scope of the Standards to include other types of apparatus than rotating machines and transformers, with which the earlier editions had been principally concerned.

The second major revision appeared in 1921. The Standards were completely revised in form and arrangement but only minor changes in substance and additions of new sections were made. This change in form consisted of the separation of the Standards into chapters containing general material applying to all types of machines, and apparatus, and chapters containing specific material applying to a particular type of apparatus. There were three of these general chapters; one on General Principles on which the Standards are based, a second on General Rules (applying to all types of apparatus), and a third on General Definitions. These general chapters were followed by thirteen chapters, each dealing with a specific type of apparatus or a specific branch of the electrical art, as, for example, rotating machines, transformers, control apparatus, wires and cables, etc.

It is perhaps worthy of note that two of the three major revisions (the third being the present one) have followed an extensive reorganization of the Standards Committee, itself.

The 1914 revision was carried out by the committee appointed August 1, 1913, which was considerably enlarged in order to permit the formation of subcommittees to care for various parts of the work. Six subcommittees were appointed to deal with such subjects as rating, (with particular reference to machines and transformers), telegraph and telephone standards, railway standards, nomenclature and symbols, wires and cables, and control apparatus. This was the first recognition, in the organization of the Standards Committee, of a major interest in Standards other than machines and transformers. Permanent subcommittees, each responsible for a part of its work, were a feature of the Standards Committee organization from that time to 1922. With the gradual increase in the scope of the Standards Committee's interests, the membership grew until in 1921-22 there were 37 members. The organization of the American Engineering Standards Committee and the increasing interest of other societies in standardization brought up many problems of policy and procedure. The consideration of these questions necessitated frequent meetings and an experienced membership familiar with the increasing complexity of organization relationships and the policies involved.

To meet these new conditions, the Standards Committee was completely reorganized by the Board of Directors of the Institute and the Committee appointed August 1, 1922, centers about a small executive committee which meets monthly or more frequently, if necessary. The formulation of Standards is entrusted to representative working committees. Each working committee is appointed for a specific task, and is discharged when that task is completed. Non-members of the Institute may be appointed on Working Committees.

Since this reorganization in 1922, thirty-nine working committees have been appointed and several hundred engineers have been actively connected with the preparation of Standards. But the regular business of directing the work has been in the hands of the small executive committee of from ten to 15 members. The Standards Committee consists of the Executive Committee, all the chairmen of active working committees and various Institute representatives on other standard-

1. Manager, Power Eng. Dept., Westinghouse E. & M. Co. Member Executive Committee, A. I. E. E. Standards Committee.

izing committees. This is a fluctuating membership and has included as many as fifty members. The principal function of the Standards Committee is to vote on the adoption of Standards completed by working committees. Thus, there are three elements in the complete organization: a small executive committee to direct the work, a flexible organization of working committees to formulate standards, expanding and contracting with the volume of work to be done, and a relatively large Standards Committee of experienced members to pass on a standard before it is approved. This form of organization has met the requirements successfully during the past three years, and, so far as can be seen at the present time, will continue to function successfully under conditions as they may be anticipated to develop in the future.

It was believed when the 1921 edition was approved that the new arrangement of the Standards would facilitate their use and make it possible to readily make changes and additions as they became necessary. Experience, however, soon developed certain defects in this edition that completely overshadowed these expected advantages.

The separation and amplification of the material in the chapter on General Principles gave this theoretical groundwork of the Standards an undue importance. The standard figures for total hottest spot temperature limits and the conventional allowances (the assumed temperature differences between hottest spot temperatures and observable temperatures) were applied too rigorously. The principle, for simplicity's sake, assumed a single value of conventional allowance for a given method of temperature measurement; actually this temperature difference varies with the total temperature, the kind of insulation and the type and dimensions of the construction employed. Many conflicts arose in determining limiting temperature rises; the rigid application led to one figure while practical experience led to a different figure. These experiences developed a strong sentiment in favor of making the application of the principle of hottest spot temperatures less rigid in arriving at practical working standards.

It was also found that the new arrangement of material adopted in the 1921 Edition of the Standards made the Standards actually less convenient in their every-day use. The material relating to any specific type of apparatus—and this was particularly true in the case of rotating machines and transformers was separated and the user of the Standards might have to look in three different chapters for the information he sought. A strong feeling developed that the material for each major class of machinery or apparatus should be collected in one place. Engineers interested in transformers, for example, prefer a single inclusive chapter on transformer standards rather than one chapter for certain general definitions, such as Classes of Insulation, another chapter for other general definitions of interest to transformer engineers, still another chapter for certain temperature limits and other rules of general application, and a fourth chapter for other temperature limits and other specific transformer standards.

The increasing scope of electrical standards and the increasing number of technical and commercial organizations interested in the subject has gradually developed the necessity of dividing the single book of A. I. E. E. Standards into a sufficient number of separate sections or pamphlets, so that the Standards for each major type of machinery or apparatus could be printed as a separate pamphlet that would be, as far as practicable, complete in itself, and could be revised without reference to any other Institute Standard. This separation of the complete body of Institute Standards into a number of separate publications had advantages, not only from the standpoint of time of revision, but also from the standpoint of the different organizations interested in different standards. There are a large number of organizations interested in one or more subjects dealt with in the A. I. E. E. Standards, but no other organization is interested in the whole body of A. I. E. E. Standards.

A final criticism of the 1921 Edition concerns the grouping of standards relating to rating and testing with standards and recommendations relating to safe operation under service conditions. The distinction between a standard test rating and permissible outputs under various conditions met with in service may require explanation and illustration. A standard "test rating" of a machine is based on its capacity under certain standardized test conditions. These are relatively simple and capable of exact definition as is required by their purpose. Two of the most important test conditions are cooling air temperature and altitude. The standard test conditions are intended to be the same as the corresponding conditions usually found in service, but the test conditions are few in number and limited in range while service conditions are infinite in variety and in combination, and vary widely in numerical values. Thus, according to the Institute Standards, tests to determine the test rating shall be made with the cooling air temperature between the limits of 10 deg. and 40 deg. and at an altitude between the limits of sea level and 1000 meters. These are "standard test conditions" and likewise "usual operating conditions." But users of electrical apparatus are interested in the outputs that can be taken safely from apparatus at various air temperatures and altitudes within and beyond the limits of standard test conditions and under other than normal conditions of voltage, frequency, power factor, etc. This has led to the demand for rules or recommendation for "operating recommendations" for conditions of service other than standard test conditions. As a simple example of this distinction between rating under standard test conditions and permissible output under various conditions encountered in service, consider a

motor having a "test rating' of 10 h. p. This is the usual nameplate rating. The same motor may also have the following permissible outputs under the given conditions:

8.5 h. p. at 50 deg. air temperature and 1000 meters altitude
8 h. p. at 4000 deg. meters altitude and 40 deg. air temperature
11.5 h. p. at 25 deg. air temperature and 1000 meters altitude
10 h. p. at 25 deg. air temperature and 2500 meters altitude

These numerical values are illustrative only; no official action has been taken to standardize such values.

There still exists some mixture of rules for rating and testing under standard test conditions and rules or recommendations for operation under service conditions in the new revision of the Institute Standards, but this edition has been greatly improved in this respect. A great deal of confusion has existed, and, to a degree, still exists in the rating situation because of a failure to distinguish clearly between a test rating, established for purposes of comparison between machines or equipment or between equipment and specifications, and the actual loading of machines and apparatus in service. Engineers, interested in the further development of electrical standards are working on this problem, and a Working Committee of the Standards Committee has been appointed to study the problem of formulating rules or recommendations concerning the performance of apparatus under service conditions.

In the new edition of the Standards, there will be, when it is completed, more than forty separate sections or pamphlets, each dealing with one major type of machinery or apparatus. Any combination of these sections can be supplied in a loose-leaf binder to suit the interests of any engineer. The following lists give those sections that are completed and those that are in an advanced stage of preparation:

Available Adopted Sections.

No. 1. (April 1925) General Principles upon Which Temperature Limits are Based in the Rating of Electrical Machinery.
5. (July 1925) Standards for Direct-Current Generators and Motors and Direct-Current Commutator Machines in General.
7. (July 1925) Standards for Alternators, Synchronous Motors and Synchronous Machines in General.
8. (March 1925) Standards for Synchronous Converters.
10. (July 1925) Standards for Direct-Current and Alternating-Current Fractional Horse-Power Motors.
11. (July 1925) Standards for Railway Motors.
13. (August 1925) Standards for Transformers, Induction Regulators and Reactors.
14. (March 1925) Standards for Instrument Transformers.
15. (Dec. 1924) Standards for Industrial Control Apparatus.
16. (July 1925) Standards for Railway Control and Mine Locomotive Control Apparatus.
19. (July 1925) Standards for Oil Circuit Breakers.
22. (July 1925) Standards for Disconnecting and Horn-Gap Switches.
30. (August 1925) Standards for Wires and Cables.
34. (June 1922) Standards for Telegraphy and Telephony.
36. (June 1922) Standards for Storage Batteries.
37. (July 1925) Standards for Illumination.
38. (March 1925) Standards for Electric Arc Welding Apparatus.
39. (July 1925). Standards for Electric Resistance Welding Apparatus.
41. (July 1925) Standards for Insulators.
42. (March 1924) Standard Symbols for Electrical Equipment of Buildings.

Sections in Preparation.

No. 2. Standard Definitions and Symbols.
4. Standards for the Measurement of Test Voltages in Dielectric Tests.
9. Standards for Induction Motors and Induction Machines in General.
12. Standards for Prime Mover and Generator Units.
20. Standards for Air-Circuit Breakers.
21. Standards for Lever Switches and Enclosed Lever Switches.
27. Standards for Switchboards.
28. Standards for Lightning Arresters.
29. Standards for Electric Railways.
33. Standards for Electrical Measuring Instruments.
35. Standards for Radio Communication.

(Sec. 1)—General Principles

The importance from a practical standpoint of the "General Principles upon Which the A. I. E. E. Standards Are Based" which appeared as Chapter 1 of the 1922 Edition has been very considerably reduced. The impossibility of rigidly applying the principle to many practical cases has been mentioned before. This basic material is of very considerable value to those interested in the formulation of standards but it has led to confusion when the attempt has been made to use it in working standards. In the new edition this material is included as Section 1 but it does not have the force or standing of rules for rating or testing. To quote the preface of this new section: "The limits of temperature and temperature rise given in this pamphlet are not limits for the rating or testing of electrical machinery. The pamphlet deals with the general considerations upon which rating limits are based."

The only temperature limits given in the revised Standards (with the exception of certain operating temperature limits given for traction motors) are the limiting temperature *rises* corresponding to the standard test rating. Total hottest spot temperatures for the different classes of insulation, conventional allowances, and the corresponding total observable temperatures have been completely eliminated from the sections dealing with machinery or apparatus standards.

In the A. I. E. E. Standards from the 1914 to the 1922 Editions inclusive, the Institute recognized three methods of temperature measurement and only in a few instances was one method definitely specified in a particular application. In the 1922 Edition, for example, Section 1001 states:

"The General Principles stated in Section 1000 permit the use of whichever method (of temperature measurement) is best suited to the class of machine, or part thereof to be tested, by introducing appropriate values for the limiting observable temperature by each method."

Table 200, Section 2230 indicated in many important instances temperature limits for both thermometer and resistance measurements and therefore, according to A. I. E. E. standards, either method could be required in an acceptance test unless the purchaser and manufacturer had agreed on a more definite program in some other way.

In distinction to this indefinite program regarding the application of the several recognized methods of temperature measurement in previous editions, the 1925 standards definitely specify the method (or, in some instances, the two methods) that shall be used in each case.

Some of the more important additions and changes made in the various sections are given in the concluding part of this article. To give all of the important change would be impossible within reasonable space limits and the reader is referred to the standards themselves for more complete information.

(Sec. 5)—Standards for Direct-Current Generators and Motors

(1) Limiting Temperature Rises. No changes have been made in temperature rises as specified in previous editions. The temperature rise for insulated windings is 50 deg. measured by thermometer. The unsettled situation existing in connection with the standard rating of general purpose motors is recognized by the following note appearing with the table of limiting temperature rises:

"The temperature limits on which the rating of general purpose motors is based are under discussion at the present time and no agreement has yet been reached. In order that work being done in this connection may not be influenced or impeded, the Institute refrains from taking any action at the present time towards revising its rules for this class of machinery."

(Sec. 2)—Shutting-Down Machine at End of Temperature Test. In d-c. machines it is very difficult to correct temperatures taken on the rotating part after shut-down for the decrease in temperature that occurs during shut-down. In order to more completely standardize the conditions of test a new rule has been added requiring machines to be shut-down within definite times. Up to and including 50 kw. this is one minute; up to and including 200 kw. it is two minutes and for still larger machines three minutes.

(Sec. 3)—Successful Commutation Defined. A new definition is included that recognizes normal maintenance as the criterion of successful commutation.

(Sec. 4)—Brush Friction. Conventional values of 8 watts per sq. in. of brush contact surface per 1000 ft. per min. peripheral speed for carbon and graphite brushes and 5 watts for metal graphite brushes are established for calculation of brush friction. If these values are not acceptable to either party the brush friction is to be measured as heretofore.

(Sec. 5.) Stray Load Losses. A very important change has been made by including stray load losses in the total losses from which the conventional efficiency is determined. These are calculated as one per cent of the output for all loads; *i. e.*, 1 per cent of the rating at full load and 0.05 per cent of the rating at half load. This new rule does not apply to motors of 200 h. p. at 575 rev. per min. and smaller. This new rule will operate to reduce the full load efficiency, which is as usually specified, one per cent.

(Sec. 7)—Standards for Alternators and Synchronous Motors

(1) Limiting Temperature Rises. Two tables of limiting temperature rises are given, one for steam-turbine driven alternators and a second for other synchronous machines. For both classes of machines, rises by embedded detectors (between coil sides) are 60 deg. for Class A insulation and 80 deg. for Class B insulation. The option of using higher temperature rises for Class B insulation (if such higher figures are the subject of special guarantee by the manufacturer) permitted by the 1914 to 1922 editions (inclusive) has been eliminated in this edition. For steam-turbine generators the limiting temperature rise of the rotor winding is 90 deg. by resistance for Class B insulation; and for lower speed synchronous machines the corresponding figures for field windings are 60 deg. and 80 deg. for Class A and B insulation, respectively. An important change has been made in the method of temperature measurement; all insulated field winding temperatures are now to be measured by resistance.

The detector method of measurement has been specified for turbine generators above 750 kv-a. in rating and for other machines above 1500 kv-a. These limits replace the 20-in. core length used in previous editions.

These limiting temperature rises and methods of measurement were adopted as international standards at the recent Hague meeting of the I. E. C., with the exception that the detector method was specified for use only on much larger machines.

This national and international agreement on Class B insulation temperature rises is a very important step forward and is a matter of congratulation among engineers interested in this class of machinery.

(2) Zero Power-Factor Method of Loading for Temperature Tests. This method of loading has been rapidly growing in favor during the past ten years and is now recognized as an approved method in this edition of the standards.

(3) Short Circuit Requirements. It is definitely specified that all synchronous machines shall be capable of withstanding short circuit when tested under conditions of no-load rated frequency and 110 per cent rated voltage. The higher voltage is intended to

compensate for the difference between no load and rated load flux.

(4) *Variations in Armature Current* present in synchronous motors driving air compressors or other machinery with reciprocating parts is limited to 66 per cent of rated current. This value was first adopted by the Electric Power Club and the American Society of Refrigerating Engineers and was accepted by the A. I. E. E. Committee.

(SEC. 8)—STANDARDS FOR SYNCHRONOUS CONVERTERS

(1) *Limiting Temperature Rises.* The temperature rises are unchanged, except that the 65 deg. rise previously specified for commutators of all commutating machines has been reduced to 60 deg.

(2) *Shutting-Down Converter at End of Temperature Test.* A rule similar to the one previously discussed in connection with d-c. machines is added. A single limit of three minutes for all converters is specified. A single limit is permissible on account of the relatively large size of the converters.

(3). *Successful Commutation Defined.* The same new definition is given for converters as for d-c. machines.

(4) *Power Factor Limitations.* A new requirement is added to the effect that all converters rated at unity power factor shall be capable of operating without dangerous heating at 98 per cent power factor. This is intended to provide only against unintentional departures from unity power factor.

(5) *Brush Friction.* The same conventional method of determining brush friction, as provided in the d-c. machine section, is included in the converter section.

(6) *Stray Load Losses.* Stray load losses are included in the conventional efficiency as one per cent of the output. In previous editions, the stray load losses were omitted. This change will have the result of reducing efficiencies, as previously calculated, 1 per cent at full load.

(SEC. 10)—STANDARDS FOR FRACTIONAL HORSE POWER MOTORS

In previous editions of the Standards fractional h. p. motors have not been distinguished from larger motors of the same types. The standards included in this section are essentially the same as for larger motors, except where the difference in size has led to different practise, as, for example, in the case of small motors, the input-output method of efficiency determination is the preferred method. The present situation, regarding the rating of general purpose motors, is recognized by the insertion of the same note, as quoted in the comments on the Direct-Current Machinery Section.

(SEC. 11)—STANDARDS FOR RAILWAY MOTORS

This section is of more than usual interest, because the Working Committee responsible for it has included in it some operating recommendations, but this has been done in a way that clearly distinguishes them from the rules concerning the standard test rating.

In a section headed "Service Conditions," there is a table of "limiting observable temperatures recommended for service." These temperatures are given as a guide to operating engineers in the every-day application and use of railway motors. These are total temperatures and include the cooling-air temperature. "Peak Values" corresponding to 40 deg. air temperature and "normal values" corresponding to 25 deg. air temperature are both given. This table is quoted below, so that it may be compared with the temperature rises given later for the test rating:

LIMITING OBSERVABLE TEMPERATURES RECOMMENDED FOR SERVICE

Method of Temperature Determination	Peak Values		Normal Values	
	Resistance deg. cent.	Thermometer deg. cent.	Resistance deg. cent.	Thermometer deg. cent.
Class A Insulation......	125	105	110	90
Class B Insulation......	145	120	130	105

In another part of the Railway Motor Standards are sections on Rating and Heating, referring to the test rating. *Temperature rises* are given for various parts of the motor for a one-hour rating and for continuous rating and for Class A and Class B insulations and for ventilated and totally enclosed motors. For the purpose of illustration the following temperature rises for armature and field windings are quoted:

	Type Enclosure	Method Temp. Meas.	Limiting Temperature Rise: One Hour Rating, Class A	One Hour Rating, Class B	Continuous Rating, Class A	Continuous Rating, Class B
Arm. and Fld Windings......	Ventilated	Resist	100	120	85	105
		Thermo	80	95	65	80
	Totally Enclosed	Resist	110	130	95	115
		Thermo	90	105	75	90

It will be noted that the temperature rises given for the continuous test rating on stand test are equivalent to the limiting observable temperatures recommended for service with average air temperature of 25 deg. cent.

An important change has been made in the standard test conditions regarding ventilation. In the 1922 and previous editions the test conditions included "with the motor covers arranged to secure maximum ventilation without external blower." This resulted in tests being made with "covers off." The revised standards provide that "Motors shall be tested with the covers and cooling system, if any, arranged as in service." This is a change in the direction of agreement between test conditions and "usual service conditions."

These American railway motor temperature rises for test rating were adopted at the recent Hague meeting of the International Electrotechnical Commission.

(SEC. 13)—STANDARDS FOR TRANSFORMERS, INDUCTION REGULATORS AND REACTORS

(1) *Altitude Correction.* For air-cooled oil-immersed apparatus the correction for temperature rises observed at high altitudes is 0.4 per cent for each 100 meters above 1000 meters instead of 1 per cent as in the previous editions. This change is based on recent experimental work.

(2) *Short Circuit Current of Transformers.* A new requirement is included that transformers shall be capable of withstanding, without injury, for two seconds a short circuit across the secondary terminals under specified service conditions. Exceptions are made in the case of auto-transformers, certain low reactance transformers, and transformers which are to be directly connected to other apparatus possessing inherent reactance.

(3) *Dielectric Test Voltages.* Important new material appears in the revised Standards concerning transformers with graded insulation and transformers tested by induced voltage. Transformers having windings with graded insulation and directly and permanently grounded shall be tested by induced voltage with connections so made that the ungrounded or line terminals shall receive test voltage to ground not less than 2.73 times the normal voltage developed by the winding plus 1000 volts. If this test does not also produce between terminals two times the rated voltage of the circuit plus 1000 volts, an additional test to produce this result shall be made.

When transformers are tested by inducing the required voltage in the winding, frequencies higher than normal are generally employed in order to avoid over-saturation in the core, and also, in the case of large transformers, to enable the test to be made with testing equipment of reasonable size. Recent experimental work by Montsinger at Pittsfield and Vogel at Pittsburgh has shown that the severity of the dielectric test increases with frequency in such rates that, for equal severity, the time should be reduced in the same ratio as the frequency is increased. For purposes of standardization the following times are used for the respective frequencies:

Frequency	Time in Seconds
120 and below	60
180	40
240	30
360	20
400	10

Considerable new material relating to induction regulators has been added to the Standards. Limiting temperature rises, method of loading for temperature tests, short-circuit current, efficiency and losses are included for the first time.

(SEC. 9)—STANDARDS FOR INDUCTION MOTORS
(*in preparation*)

This section is largely a collection of previously existing A. I. E. E. Standards, relating to induction machines. The definitions have been revised and new definitions have been added for the *squirrel-cage induction motor, wound rotor induction motor, induction frequency converter* and *"slip"*.

Shutting-Down Machines at End of Temperature Run. When the stopping time is limited to specified values, no correction of observed temperatures is required. These values are the same as for d-c. machines:

Up to and including 50 h. p.	1 minute
Above 50 h. p. and including 200 h. p.	2 minutes
Above 200 h. p.	3 minutes

Stray Load Losses. The 1922 Standards specified a method for measuring stray load losses in induction machines, but also stated:

"In windings consisting of relatively small conductors, these eddy-current losses are usually negligible."

The specified method of measuring these losses—with rotor removed—has seldom been used in practise, and stray load losses have usually been neglected. In the 1925 revision, the following provisions have been incorporated:

"Stray Load Losses. In induction machines, no allowance for stray load losses shall be included."

A footnote calls attention to the fact that stray-load losses may be considerable, if the primary winding contains conductors more than 3/8 in. in depth in a 60-cycle machine. Modern designs use conductors considerably smaller than this.

Rating of Elevator Motors. A new paragraph has been added which is the same as the previously existing Electric Power Club Standard.

STANDARDS FOR INDUSTRIAL CONTROL APPARATUS

In the 1922 Standards, Industrial Control Standards were grouped with switching, circuit breakers, and protective apparatus. No distinction was drawn between the different apparatus and general conditions existing in the industrial field and in the field of power supply. The separation of these diverse kinds of equipment into a number of separate sections has led to a considerable increase in material and a general improvement in these standards.

The new material in Industrial Control Standards mainly concerns limiting temperature rises, conditions and methods of making temperature tests and limitations other than heating, such as range of operating voltage for contactors, test for operation at minimum voltage, durability test and tests to determine successful operation.

This section has the distinction of being the first section to be given the status of an American Standard under the procedure of the American Engineering Standards Committee. This American Standard was sponsored jointly by the Electric Power Club and the A. I. E. E.

STANDARDS FOR OIL CIRCUIT BREAKERS

Considerable new material relating to rating of oil circuit breakers has been included. This material, while new to the A. I. E. E. Standards, is well established in the practise of the industry.

STANDARDS FOR INSULATORS

This is an entirely new specification, and is the result of painstaking work on the part of a representative group of engineers during the past three years. It is essentially a test specification and prescribes procedure, in considerable detail, for both pin- and suspension-type insulators.

STANDARDS FOR ELECTRICAL MEASURING INSTRUMENTS (*in preparation*)

This is another wholly new standard and is a good example of the cooperation that exists between the technical committees of the Institute and the Standards Committee. This section first appeared as an Institute paper by H. B. Brooks, prepared under the direction of the Technical Committee on Instruments and Measurements. A Working Committee of the Standards Committee is now putting the section in suitable form for approval—using the Brooks paper as a basis.

These are the more important changes and additions to be found in the new edition of the Institute Standards. It is confidently believed that this edition will prove a worthy successor to the long line of older editions, and that it will serve the industry in even greater measure.

ONE GENUINE METHOD OF SOLVING THE AUTOMOBILE HEADLIGHT PROBLEM

Possession of a little card, signifying that the bearer thereof has expended seventy-five cents to have his automobile headlights tested and adjusted, has not solved the problem of automobile headlight glare. On paper the theory sounds very well, but in practise there are a number of conditions which shake its security. Every road bump, every car track, every vibration constitutes one of these mitigating conditions.

It is not enough to conform to the letter of the law once or twice a month by visiting headlight-testing stations. It helps the motorist who has to look into glaring headlights not one whit, if after leaving the testing stand, a jar or a twist will leave the lights of any given car in position to blind everyone into whose range they come. No amount of legislation nor even of testing and adjusting can prevent glare from strong headlights along rolling road-beds.

Like many another panacea, the remedy has been applied to the effect rather than the cause; the fact remains that roads are not ideal in contour, and even perfect adjustment does not prevent a car coming up over a rise in the road from sending its perfectly focused rays full into the eyes of drivers approaching on the other side.

Yet there is a way to remedy the condition that is not dependent on law enforcement. It consists of illuminating the highways scientifically.

Regardless of road conditions, regardless of the condition of the apparatus of the individual cars that traverse them, scientific highway lighting will be uniform.

The idea carries with it commercial possibilities to the electrical industry, naturally, but more than that it will bring satisfaction that the problem is being solved in the best and most sensible way. The success of street lighting, where illumination has been the chief object sought rather than mere ornament, has brought forth as a by-product this vision of highway illumination potentialities. That the headlights of an automobile are practically unnecessary on well-lighted streets has suggested that highways might be made safe in the same manner.

The electrical industry is not the only one which will profit from highway illumination. Tests made recently on a stretch of highway in the East have demonstrated actually by count that without altering the highway traffic could be increased 100 per cent by having them well lighted. Practically all the trucking load upon highways is carried at night. With well-lighted highways the amount of trucking over highways can be increased 100 per cent, the experiment proved, and the highways still remain safe for traveling motorists.—*Journal of Electricity*, November 1, 1925.

KILOCYCLE-METER CONVERSION TABLE

There is increasing tendency in radio practise to use radiofrequencies in kilocycles rather than wave lengths in meters. "Kilo" means a thousand, and "cycle" means one complete alternation. The number of kilocycles (abbreviated kc.) indicates the number of thousands of times that the rapidly alternating current in the antenna, transmitting set, or receiving set repeats its flow in either direction in one second.

The bureau has just issued in chart form a "Kilocycle-Meter Conversion Table." It is Miscellaneous Publication No. 67 and replaces Letter Circular No. 123 of January 27, 1925. The table is printed on a single sheet of cardboard and can be posted in a convenient place for ready reference. (Copies may be obtained for 5 cents each from the Superintendent of Documents, Government Printing Office, Washington, D. C.)

The table gives accurate values of kilocycles corresponding to any number of meters and vice versa. The table gives values for every 10 kilocycles or meters, and is entirely reversible; that is, for example, 50 kilocycles is 5996 meters and also 50 meters is 5996 kilocycles. The range of the table is from 10 to 10,000 kc. (10,000 to 10 m) and this can be extended in either direction by changing the decimal point.

Transmission Systems with Over-Compounded Voltages

BY H. B. DWIGHT[1]

Member, A. I. E. E.

***Synopsis.**—A usual method of calculating a transmission line with transformers, in which the voltage is held constant at both ends by synchronous condensers, is to use the circle diagram method. It is often advisable to use "over-compounded" voltage instead of constant voltage; that is, to increase the voltage as the load increases. Methods of calculation are given in this paper for two cases, first with over-compounded generator voltage and constant receiver voltage, in which case the diagram is a circle, and second, with over-compounded voltage at both generator and receiver, in which case the diagram is an ellipse. Examples are given and the diagrams are shown in Fig. 2.*

A short discussion is given of the advantages and limitations of using over-compounded voltage.

* * * * *

It is a very usual practise to control the station voltages of transmission systems by automatic voltage regulators, which adjust the field currents of generators and synchronous condensers so that the desired voltages are obtained. In such cases, very great advantages are obtained in many stations by maintaining a higher voltage at a time of heavy load than at a time of light load. This may be called "over-compounded voltage," and can be easily accomplished by means of a simple arrangement with an automatic voltage regulator, which is often called line drop compensation. One of the most common methods of producing line-drop compensation is to put a few turns of winding, carrying current from series transformers, on the magnet of the relay which controls the voltage. These series ampere-turns usually amount to not more than about 25 per cent of the ampere-turns of the shunt winding, which is the main winding. Therefore, the result is that, at no load, the main winding operates the regulator so as to produce a certain voltage. With load conditions and the series winding opposing the shunt, a higher voltage is necessary before the regulator will operate; therefore, a higher voltage than at no load is maintained.

A somewhat similar arrangement to give over-compounded voltage is frequently provided with induction voltage regulators.

Advantages of Over-Compounded High-Tension Voltage

The statement is sometimes made that the voltage supplied to a certain customer or city by a transmission system should have not more than a specified amount of variation, say five per cent. Where such a statement is made, it practically always refers to "under-compounded" voltage; that is, the voltage variation is caused by the load and the voltage is low at times of heavy load. It is evident that, if a voltage of 12,000 volts or higher is under-compounded, then circuits of 2300 or 115 volts will be still more under-compounded due to the drop in the intervening transformers and lines at full load. If the higher voltage is over-compounded, then the drop in transformers and lines tends to decrease the variation in the distribution voltage instead of increase it.

It can be stated that, in general, twice as much over-compounding as under-compounding of a circuit of 12,000 volts or higher can be allowed for the same amount of inconvenience and for the same necessity of using feeder voltage regulators. In reality, the circuits which feel the disadvantage of voltage variation most are 115-volt circuits, where changes in voltage are noticeable at once in the changed brightness of lamps. Voltage variation in 2300-volt circuits is often inconvenient mainly because it causes variation in the connected 115-volt circuits. Slightly over-compounded voltage on a motor circuit is not very disadvantageous, for low voltage is most liable to occur out of working hours, when there is light load on the power system. Such an arrangement is the least troublesome, and further, is economical, for the core loss of transformers and motors is reduced during the night when they are giving what is often practically only stand-by service. Good speed and good starting torque and pull-out torque in induction motors are especially desirable when loads are heavy, and these are all helped by over-compounded voltage.

It may be said that over-compounded voltage on circuits operating at greater than 115 volts is more desirable than constant voltage or under-compounded voltage, in almost every case. This is true for practically any customer, city, or place where there are generators, synchronous condensers or induction regulators to give control of the voltage; but it is particularly true of the generating end of long transmission lines. Where there is an appreciable amount of charging current, at no load the equivalent voltage at the generator terminals must be lower than at the load end with no synchronous condensers connected, due to the reactance of the transformers and of the line. However, it would not be economical to operate the generators always at this low voltage, since this would involve greater resistance loss and a larger rating of synchronous condensers if such are used for voltage regulation. The generators at full

---

1. Mass. Inst. of Technology.

To be presented at the Midwinter Convention of the A. I. E. E., New York, N. Y., Feb. 8-11, 1926.

load should be operated at full rated voltage. It is also, in many cases, inadvisable to operate the generators at constant full rated voltage, for this produces too high a voltage at the distant end at no load, necessitating delay when starting to put the synchronous condensers on the line for even a small amount of load, or for paralleling with other lines. Unduly high voltage increases strain on the insulation and produces trouble in the generating station in handling the charging current. Accordingly, if automatic voltage regulators are used, as is generally the case with long transmission lines, they should, if possible, be adjusted for a moderate amount of over-compounding of the voltage rather than for constant voltage. It is fortunate that the over-compounding is practically proportionate to the true kilowatt load, and is not appreciably affected by the quadrature charging current.

Where there are several generators in a station often only one or two are used to carry the load in the middle of the night. At such time each generator should have less amount of compounding than it would have when the entire station is operating. However, since the over-compounding or line-drop compensation feature can be reduced or cut out by merely turning a dial on the voltage regulator, it is not difficult to do this at times when the number of generators operating in the station is changed. It is also possible to take the current for the series coils of the regulators from a current transformer carrying the total load of the entire station. This will give the same over-compounding for the station regardless of the number of generators in operation.

Most Advisable Amount of Over-Compounding

The question as to how much over-compounding of the voltage should be used in a transmission system is not so much a question of design as of operation, for the over-compounding will be limited in most cases to a comparatively small percentage by operating considerations.

Transmission lines over 100 miles long cost considerably more than the synchronous condensers used to control their voltage. Consequently, it pays to install synchronous condensers sufficient to maintain the line at nearly rated voltage in all parts when it is fully loaded. If the line current at the load end has a very low leading power factor, its resistance loss and, what is more important, its stability will usually be improved by putting part of the synchronous condensers in an intermediate substation.

The voltages to be maintained with long lines at light load and no load will depend mainly on the method considered desirable for starting up the transmission system; whether the generators are to be thrown on the line alone or on sections of it; whether the synchronous condensers are to be started and adjusted for lagging power factor before connecting on any load; or whether the generators are to be brought up from zero speed, together with the synchronous condensers.

With lines shorter than 100 miles, the cost of synchronous condensers becomes of greater relative importance, because the cost of the lines is proportionately less. The cost of condensers is usually compared with the cost of more or heavier transmission circuits.

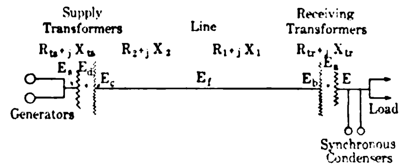

Fig. 1—Scheme of Connections of Transmission System

The question of the amount of voltage variation to be allowed on low voltage circuits depends on the standard set in different localities for different classes of load. This standard is maintained in practical operation by installing more circuits, transformers and induction feeder regulators in the lower voltage parts of the system, as well as by improving conditions in the higher voltage parts.

A certain amount of over-compounding on the higher voltage circuits will generally help to maintain the above standard. How far this can be carried is a matter on which only a small amount of data has been collected or published. An investigation on actual systems as to how much over-compounding can be used under different conditions before real practical disadvantages are encountered would be valuable.

Where there is no load to be supplied close to the generators, over-compounding up to about 25 per cent at the generators can be used. If loads are supplied directly from the generator bus-bars, a smaller amount of over-compounding must be used, the amount depending on whether the power passes once or twice through transformers before it is used by motors or lamps, and on whether the load curve of the local load throughout the day corresponds closely with the load curve of the generator load.

In conclusion, it is generally advisable to use as much over-compounding at any point as experience shows can be used without interfering with the accepted standards of good maintenance of voltage in the different low-voltage circuits of the system. A small percentage of over-compounding can be used on high-tension circuits at load points and a larger percentage, amounting in some cases to as much as 25 per cent, can be used at generating stations.

Calculation of Lines Having Over-Compounded Voltage

A very convenient method of calculating the electrical behavior of a transmission line or system provided with synchronous condensers is to draw the circle

diagram showing the reactive kv-a. required from the synchronous condensers at various loads, the step-up and step-down transformers being taken into account[2]. In the present paper, the method of calculation is extended to cover the case of over-compounded generator voltage and constant receiver voltage, for which case the diagram is a circle. An extension of the calculation is also given to cover the case of over-compounded voltage at both generator and receiver and in this case, the diagram is not circular but elliptical. Examples are given and the resulting diagrams are shown in Fig. 2.

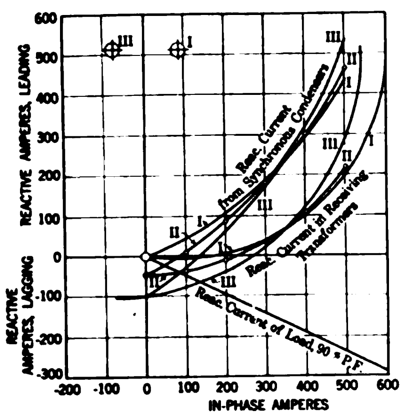

FIG. 2— I. OVER-COMPOUNDING AT GENERATOR END
II. OVER-COMPOUNDING AT BOTH ENDS
III. CONSTANT VOLTAGE AT BOTH ENDS

A solution for the case of over-compounded generator voltage and constant receiver voltage has been published using the method of the equivalent π line[3].

CALCULATION FOR LINE AND TRANSFORMERS, WITH OVER-COMPOUNDED GENERATOR VOLTAGE AND CONSTANT RECEIVER VOLTAGE

Numerical values, except for $(P + jQ)$ which always appears, are to be found for the following quantities:

Current in secondary of receiving transformers:

$$I_a = P + jQ + P_c \text{ amperes per conductor} \quad (1)$$

Voltage induced in receiving transformers:

$$E_a = E + \frac{1}{2} I_a (R_{tr} + j X_{tr}) \text{ volts to neutral} \quad (2)$$

Current in primary of receiving transformers:

$$I_b = I_a + E_a (G_{tr} + j B_{tr}) \text{ amperes per conductor} \quad (3)$$

Voltage at receiving end of transmission line:

$$E_b = E_a + \frac{1}{2} I_b (R_{tr} + j X_{tr}) \text{ volts to neutral} \quad (4)$$

2. "Electrical Characteristics of Transmission Systems," by H. B. Dwight, TRANS. A. I. E. E., Vol. 41, 1922, page 781.

3. "Regulator Settings for Long Lines," by L. F. Woodruff, *Electrical World*, August 30 and September 6, 1924.

Voltage at a point f where the conductor or spacing is changed but not where the voltage is controlled:

$$E_f = E_b \left(1 + \frac{Y_1 Z_1}{2} + \frac{Y_1^2 Z_1^2}{2 \times 3 \times 4} + \ldots\right) + I_b Z_1 \left(1 + \frac{Y_1 Z_1}{2 \times 3} + \frac{Y_1^2 Z_1^2}{2 \times 3 \times 4 \times 5} + \ldots\right)$$

volts to neutral (5)

Current at point f:

$$I_f = I_b \left(1 + \frac{Y_1 Z_1}{2} + \frac{Y_1^2 Z_1^2}{2 \times 3 \times 4} + \ldots\right) + E_b Y_1 \left(1 + \frac{Y_1 Z_1}{2 \times 3} + \frac{Y_1^2 Z_1^2}{2 \times 3 \times 4 \times 5} + \ldots\right)$$

amperes per conductor (6)

Y_1 and Z_1 are the admittance and the impedance of the line from b to f.

Voltage at supply end of transmission line:

$$E_c = E_f \left(1 + \frac{Y_2 Z_2}{2} + \frac{Y_2^2 Z_2^2}{2 \times 3 \times 4} + \ldots\right) + I_f Z_2 \left(1 + \frac{Y_2 Z_2}{2 \times 3} + \frac{Y_2^2 Z_2^2}{2 \times 3 \times 4 \times 5} + \ldots\right)$$

volts to neutral (7)

Current at supply end of transmission line:

$$I_c = I_f \left(1 + \frac{Y_2 Z_2}{2} + \frac{Y_2^2 Z_2^2}{2 \times 3 \times 4} + \ldots\right) + E_f Y_2 \left(1 + \frac{Y_2 Z_2}{2 \times 3} + \frac{Y_2^2 Z_2^2}{2 \times 3 \times 4 \times 5} + \ldots\right)$$

amperes per conductor (8)

Y_2 and Z_2 are the admittance and the impedance of the line from f to c.

Voltage induced in supply transformers:

$$E_d = E_c + \frac{1}{2} I_c (R_{ts} + j X_{ts}) \text{ volts to neutral} \quad (9)$$

Current in primary of supply transformers:

$$I_d = I_c + E_d (G_{ts} + j B_{ts}), \text{ amperes per conductor.}$$
$$= C + jD = \text{current at generator terminals.} \quad (10)$$

Voltage at generator terminals:

$$E_s = E_d + \frac{1}{2} I_d (R_{ts} + j X_{ts}) \text{ volts to neutral}$$
$$= A + jB$$
$$= E_{os} + L_s I_d \quad (11)$$

Equation for circle diagram:

$$E_{os} = E_s - L_s I_d \text{ volts to neutral}$$
$$= E' + jE'' + (P + jQ)(R' + jX') \quad (12)$$

Quantities required for above equations (referring to a three-phase system):

$P + jQ$ = Load current + reactive current from synchronous condensers. This is always

expressed by letters in the above calculation.

P_c = Current for average loss in synchronous condensers.

E = Equivalent high-tension voltage at low-tension side of receiving transformers, in volts to neutral.

R_{tr} = Equivalent high-tension resistance from line to neutral of receiver transformers.

If the resistance is given in per cent,

$$R_{tr} = \frac{\text{Per cent resistance} \times E^2}{100{,}000 \times \text{kv-a. per phase}} \qquad (13)$$

X_{tr} = Equivalent high-tension reactance from line to neutral of receiver transformers. If the reactance is given in per cent,

$$X_{tr} = \frac{\text{Per cent reactance} \times E^2}{100{,}000 \times \text{kv-a. per phase}} \qquad (14)$$

It is assumed in equations (**2**) and (**4**) that, so far as the magnetizing current is concerned, the transformer impedance is equally divided between the primary and secondary. If the division is more accurately known, the actual values of primary and secondary impedance can be used.

$G_{tr} + j\,B_{tr}$ = Admittance (equivalent high-tension) for core loss and magnetizing current of receiver transformers at average voltage. If these characteristics are given in per cent,

$$G_{tr} = \frac{\text{Per cent core loss}}{100} \times \frac{1000 \times \text{kv-a. per phase}}{E^2} \qquad (15)$$

and

$$B_{tr} = -\frac{\text{Per cent magnetizing current}}{100} \times \frac{1000 \times \text{kv-a. per phase}}{E^2} \qquad (16)$$

B_{tr} is a negative quantity.

The characteristics of the supply transformers are denoted by the letters $t\,s$ as in R_{ts}, etc.

The point f denotes a place in the transmission line where the line characteristics change due to different conductor or spacing. A constant load may be assumed for this point without changing the form of the calculation. However, it is not to be assumed that the voltage is controlled at this point, for if it were, a circle diagram would have to be calculated as far as f, and another diagram for the remainder of the transmission system. Other points g, h, etc., similar to f, can readily be included in the calculation.

$Y_1 = G_1 + j\,B_1$, the admittance of the line from b to f.

$Z_1 = R_1 + j\,X_1$, the impedance of the line from b to f.

The subscript (**2**) denotes the characteristics of the line from f to c, as in Y_2, etc.

The series in $Y\,Z$ are very convergent at commercial frequencies and can be quickly calculated. It may be noted that

$$1 + \frac{Y_1 Z_1}{2} + \frac{Y_1^2 Z_1^2}{2 \times 3 \times 4} + \ldots = \cosh \sqrt{Y_1 Z_1}$$

and

$$1 + \frac{Y_1 Z_1}{2 \times 3} + \frac{Y_1^2 Z_1^2}{2 \times 3 \times 4 \times 5} + \ldots = \frac{\sinh \sqrt{Y_1 Z_1}}{\sqrt{Y_1 Z_1}}$$

E_{os} is a quantity whose absolute value is equal to that of the equivalent high-tension voltage at the generator terminals at no load. Only the absolute value of E_{os} is made use of in the calculation in this paper. The phase of the quantity E_{os} changes as the load changes, and so E_{os} cannot be considered as a constant nor as a complete representation of the no-load voltage. The reason for this is that the automatic regulator maintains the absolute value of the voltage according to the last part of (**11**), but it has no power to alter the phase of the voltage.

L_s is a measure of the over-compounding of the voltage, or the line drop compensation. It is equal to the rise in equivalent high-tension voltage produced by one ampere of current (equivalent high tension) in phase with E_s.

Circle Diagram. Since equation (**12**) is of the same form as the equation for a constant-voltage transmission line, a circle diagram may be drawn for the transmission system with over-compounded voltage at the generator end. Since E, the load voltage, is constant, the values of current may be multiplied by

$$\frac{3\,E}{1000}$$

to give kw. and reactive kv-a. as in Reference 1. However, where the voltage is varying, it is desirable to keep account of the current and voltage rather than the kv-a., and so the circle diagram equations are given here in terms of amperes.

The center of the circle is the point (a', b') where

$$a' = -\frac{E'\,R' + E''\,X'}{R'^2 + X'^2} \text{ amperes} \qquad (17)$$

$$b' = +\frac{E'\,X' - E''\,R'}{R'^2 + X'^2} \text{ amperes} \qquad (18)$$

The radius is

$$c' = +\frac{E_{os}}{\sqrt{R'^2 + X'^2}} \text{ amperes} \qquad (19)$$

The circle shows the reactive current at the receiver end of the line plotted on values of in-phase current at the receiver end.

In order to plot the reactive current required from the synchronous condensers, first draw a straight line at angle θ below the base line, where $\cos\theta$ is the power factor, lagging, of the load. If the power factor is not the same at all loads, the line will not be straight, but will be a curve showing the reactive current of the load from no load to full load. By means of a pair of dividers add the reactive current of the load to the corresponding ordinate of the circle, thus plotting the curve of current required from the synchronous condensers. This curve is an ellipse when $\cos\theta$ is constant. (See Fig. 2).

Circle Diagram Limit of Load.

$$\text{Maximum Load} = c' + a' \text{ in-phase amperes} \qquad (20)$$

This is numerically less than c' when a' is a negative quantity, and greater than c' when a' is positive. It may be read from the circle diagram, as it is the farthest distance to the right reached by the circle. It is a useful point to locate on the diagram before drawing the circle, as is also the bottom point of the circle, $(a', b' - c')$. It assists in drawing the circle to have these two points through which the circle is to pass.

The "stability limit" of load is usually somewhat less than the circle diagram limit, and of course, in the operation of a transmission line, neither limit must be reached.

Calculated Value of Reactive Current.

A direct calculation of the reactive current is more precise than a reading from the circle diagram, and is less work than a trial and error method. The value of the reactive current in the circuit, Q, for a given in-phase current P, may be found from the following equation:

$$(b' - Q)^2 = c'^2 - (P - a')^2 \qquad (21)$$

First, find the value of the right hand side of the equation. Then take the square root and subtract b'. The reactive current required from the synchronous condensers is equal to

$$Q + P\frac{\sin\theta}{\cos\theta} \text{ amperes} \qquad (22)$$

where the in-phase current is P amperes and the lagging power factor is $\cos\theta$. It should be remembered that b' is a positive quantity and a' may be positive or negative. It is worth while checking the results of equations (**21**) and (**22**) by drawing the circle diagram and obtaining the same results graphically.

Concentric Circles. Since a' and b' which give the center, are independent of E_{o}, and since the radius c' is directly proportional to E_{o}, a number of circles corresponding to different values of E_{o} may be drawn about the same center.

Total Losses. The losses in the transmission system for a given power load are

$$\frac{3}{1000}(A\,C + B\,D - E\,P) \text{ kw.} \qquad (23)$$

P is determined by the power load. Then Q must be found from the circle diagram or equation (**21**). Then A, B, C and D can be found from equations (**10**) and (**11**), for which numerical coefficients have already been obtained.

Efficiency of the transmission system

$$\text{Efficiency} = \frac{100\,E\,P}{A\,C + B\,D} \text{ per cent} \qquad (24)$$

Kw. at supply end of system

$$\frac{3}{1000}(A\,C + B\,D) \text{ kw.} \qquad (25)$$

Kv-a. at supply end

$$\frac{3\,E_s\sqrt{C^2 + D^2}}{1000} \text{ kv-a.} \qquad (26)$$

Power factor at supply end

$$\frac{100\,(A\,C + B\,D)}{E_s\sqrt{C^2 + D^2}} \text{ per cent} \qquad (27)$$

Reactive kv-a. at supply end

$$\frac{3}{1000}(A\,D - B\,C) \text{ kv-a.} \qquad (28)$$

When this quantity is positive the reactive kv-a. and the power factor are leading, and when it is negative they are lagging.

Over-Compounded Voltage at Both Supply and Receiver Ends of System

The receiver voltage can be over-compounded when there are synchronous condensers, by using exactly the same kind of apparatus as that used to provide over-compounded voltage at the supply end. The diagram in this case is not a circle, but an ellipse, and so values of Q for different values of P are found by calculation.

If L_r is the rise in equivalent high-tension voltage at the receiver end produced by one ampere of current (equivalent high-tension) in phase with E, then

$$E_s = E - L_r\,P - j\,L_r\,Q$$

as in eq. (**12**). The phase of E_s in the above expression changes as the load changes. Its absolute value is equal to that of the equivalent high-tension voltage at the receiver end at no load. P is in phase with E.

The absolute value of E_s is equal to

$$E - L_r\,P + \frac{(L_r\,Q)^2}{2\,(E - L_r\,P)} \qquad (29)$$

$L_r\,P$ is usually less than 25 per cent of E for any load that the line is to carry. If $L_r\,Q$ is 20 per cent of rated voltage, the third term of (**29**) is less than three per cent of E. It is therefore seen that the quadrature current Q has very little effect on the voltage, and the over-compounding of the voltage or the line-drop compensation is practically proportional to the in-phase current or the true kilowatt load.

In the calculations in this paper the third term of (**29**) is neglected, and we write

$$E = E_o + L_r P \qquad (\mathbf{30})$$

Now evaluate expressions (**1**) to (**12**). The quantity $(P + j\,Q)$ will not be a factor as it was in the previous case, but P and Q will now have different numerical coefficients. The final expression as given by (**12**) is

$$E_{os} = E_s - L_s I_d$$

If a numerical value is assigned to P, this becomes an equation in complex quantities involving Q. E_{os}^2 is equal to the square of the real part of the right hand side plus the square of the imaginary part. This is equivalent to multiplying each side of the equation by its conjugate, that is, by a complex quantity equal to itself except that the sign of the imaginary part is changed. The result is an ordinary quadratic equation in Q, of the form

$$a\,Q^2 + b\,Q + c = 0.$$

Q is given by

$$Q = \frac{-\,b - \sqrt{b^2 - 4\,a\,c}}{2\,a}$$

The minus sign of the radical is to be used so as to give the normal working part of the curve, corresponding to the lower part of the circle diagram for constant receiver voltage.

Example I

Draw the circle diagram for the following line and transformers, with constant receiver equivalent high-tension voltage 200,000 volts between conductors, no-load equivalent high-tension voltage 183,000 volts between conductors at generators, and 220,000 volts at generators with in-phase current of 355 amperes.

Length of line = 200 miles.
Frequency = 60 cycles.

$$R + j\,X = 23.2 + j\,160 \text{ ohms.}$$
$$Y = +\,j\,0.00106 \text{ mho}$$

$$1 + \frac{YZ}{2^2} + \ldots = 0.91637 + j\,0.01195$$

$$1 + \frac{YZ}{2.3} + \ldots = 0.97197 + j\,0.00403$$

$$P_c = 8.66 \text{ amperes}$$
$$R_{tr} + j\,X_{tr} = 1.33 + j\,24.0 \text{ ohms.}$$
$$G_{tr} + j\,B_{tr} = 0.000{,}022{,}5 - j\,0.000{,}187{,}5 \text{ mho}$$
$$R_{ts} + j\,X_{ts} = 1.61 + j\,29.0 \text{ ohms.}$$
$$G_{ts} + j\,B_{ts} = 0.000{,}018{,}6 - j\,0.000{,}155{,}0 \text{ mho.}$$

The calculation is the same as for Example I, Reference 2, as far as the equation,

$$E_s = 107{,}050 + j\,3340 + (P + j\,Q)\ (23.9 + j\,204.4)$$

Then, the absolute value of $E_{os} = 105{,}850$ volts to neutral.

$$L_s = \frac{127020 - 105850}{355} = 59.8$$

$$E_{os} = 106{,}310 - j\,1610 + (P + j\,Q)\ (-\,31.3 + j\,203.6)$$
$$= E' + j\,E'' + (P + j\,Q)\ (R' + j\,X')$$

The center of the circle is the point (a', b') where

$$a' = +\,86.2 \text{ amperes}$$

and

$$b' = +\,509.2 \text{ amperes}$$

The radius of the circle is

$$c' = +\,513.8 \text{ amperes.}$$

See Curve I, Figure 2.

Example II

Draw the diagram for the same line and transformers as in Example I, with the same over-compounding of the voltage at the generator end, and with over-compounding at the load end from 182,000 volts at no load to 200,000 volts at 346 in-phase amperes.

$$L_r = \frac{115{,}470 - 105{,}000}{346} = 30.2$$

$$E = 105{,}000 + 30.2\,P$$
$$I_a = P + j\,Q + 8.7$$
$$E_a = 105{,}000 + j\,100 + P\,(30.9 + j\,12.0) + j\,Q\,(0.674 + j\,12.0)$$
$$I_b = P\,(1.003 - j\,0.006) + j\,Q\,(1.002 + j\,0.0002) + 11.1 - j\,19.7$$
$$E_b = 105{,}240 + j\,220 + P\,(31.6 + j\,24.0) + j\,Q\,(1.3 + j\,24.0)$$
$$E_c = 99{,}740 + j\,2760 + P\,(51.5 + j\,178.4) + j\,Q\,(22.8 + j\,178.0)$$
$$I_c = P\,(0.894 + j\,0.039) + j\,Q\,(0.894 + j\,0.013) + 9.7 + j\,90.5$$
$$E_d = 98440 + j\,2970 + P\,(51.6 + j\,191.4) + j\,Q\,(23.3 + j\,191.0)$$
$$I_d = P\,(0.925 + j\,0.035) + j\,Q\,(0.924 + j\,0.013) + 12.04 + j\,75.2$$
$$E_s = 97360 + j\,3200 + P\,(51.8 + j\,204.8) + j\,Q\,(23.8 + j\,204.4)$$
$$E_{os} = 96640 - 3.4\,P - 203.6\,Q - j(1300 - 202.7\,P + 31.4\,Q)$$

In calculating the point on the curve for $P = 300$,

$$E_{os} = 95620 - 203.60\,Q + j\,(59510 - 31.4\,Q)$$

Absolute value of $E_{os} = 105{,}850$.

Dividing by 100 and then squaring the real part and the imaginary part,

$$4.244\,Q^2 - 4267\,Q + 148{,}000 = 0$$

$$Q = \frac{4267 - 3961}{8.488}$$

$$= +\,36.0 \text{ amperes.}$$

This is plotted on Curve II in Fig. 2.

Example III

Draw the circle diagram for the same line and transformers as in Example I, except that there is to be constant voltage at both ends. This is the same as Example I, Reference 2, except that the results are expressed in amperes. The result is Curve III, Figure 2 of this paper.

Properties of the Single Conductor

New Fundamental Relations

BY CARL HERING[1]

Fellow, A. I. E. E.

Synopsis.—*The properties of a unit length of single, straight conductor, far removed from all other circuits, are investigated to endeavor to find whether such a unit is a basic, fundamental one, on which deductions and a method of mathematical treatment could be based, as was advocated by Ampere, to supplement (not to replace) the Maxwell system based on a complete circuit, and to test the correctness of some of the postulates now in common use, based on the latter system. By several new, simple, and direct proofs based only on a few well-established and accepted relations, chiefly the internal stresses in a conductor, but excluding infinities, self-inductances, induction, and any postulates, a constant is deduced for the energy stored by a current in such a unit length, which seems to be one of the most fundamental, basic constants in electrodynamics, from which many useful deductions can be made, some of which are given. This energy of the flowing current corresponds to the* $m\,v^2/2$ *energy of moving masses.*

Some of the results differ from those which have been in use; explanations are offered of the cause of these differences, and it is shown how the results may be brought into agreement, involving some changes in our previous conceptions. It is shown that with flux lines a distinction ought to be made which is analogous to that which distinguishes the wattless ampere from the one in phase, or between a true resistance and an impedance; it is shown why what might be called wattless flux, ought to be recognized. It is shown that self-inductance is used in two senses which may sometimes lead to different results, and that a distinction should therefore be made between them somewhat analogous to that between resistance and impedance or reactance. This it is believed would clear up the ambiguity now existing in that term. It is believed that some of these results could not have been obtained from the Maxwell complete circuit system, which rather leads one away from them.

* * * * *

INTRODUCTORY

IN science, as in engineering and mathematics, it is always desirable to have two independent methods of getting a result; they not only afford a very desirable check on the result and on each other, but each one often has advantages over the other in the different fields for which it is best adapted. For the analytical treatment of electric currents and circuits, the "complete circuit" system of Maxwell has been taught universally and exclusively and for so many years that the strong though wrong belief has arisen among many that it is the only possible one, and that every case must be treated from that and only from that standpoint. In some cases this has not only misled us but has sometimes even led us away from useful facts and relations.

There is a second and older system, the one advocated by that great mathematical physicist Ampere, which is based on the single conductor, and which has many advantages over the other in specific fields for which it is better adapted. Neither system should be used to completely replace the other; they should be used to supplement each other, each in its own field. An electron may start from rest, move to another point and come to rest again there, as in a bolt of lightning; while moving, it is a current and generates a magnetic field in which energy is stored, quite analogous to the $m\,v^2/2$ energy stored in a moving body. The "complete-circuit" system is a misfit in such a case and involves complications which are burdensome and confusing to the student, while the single-conductor system applies directly.

On the other hand the complete-circuit system lends itself well to integrations around a completed path. It has served its purpose well and is very useful, and in most of the usual circuits it is quite reliable. But in a search for the true, basic, fundamentals, there is no such a thing as a fundamental or unit or limiting circuit; the nearest approach to one is a circular circuit in the form of a tore or torus whose centerline radius is equal to the radius of the wire, like a doughnut with an infinitely small hole through it. This is the shortest circuit which can be made with a wire of given diameter, hence is at least a limit, but for various reasons this is not satisfactory as an ultimate fundamental.

The writer has therefore concluded that the only real fundamental is a unit length of a long straight, single, conductor, far removed from all others, as this embodies absolute ultimata; it is the form which is most free from all external influences, and besides the current, it involves the least number of variables, in fact only one, the radius of the wire, and even that one falls out in some cases, as will be shown below, for relatively to the infinite free space around it for the magnetic flux, the small finite radius of the wire becomes negligible.

The purpose of the present paper is to examine analytically the properties of such a unit length of this fundamental conductor, without involving infinities, the limitations of complete circuit mathematics, self-inductances, induction, postulates, or any but well established relations, and to deduce from these properties any useful relations and constants that may exist.

To do so by considering a straight line as a special case of a circle of infinite radius, is unsatisfactory, as it introduces that dangerous quantity, infinity, with its serious pitfalls into which many otherwise able men

Abridgment of a paper to be presented at the Midwinter Convention of the A. I. E. E., New York, N. Y., February 8-11, 1926. Complete copies available to members upon request.

have fallen[2]. In a French book by Fleury dealing with infinity he says: "Infinity has no other property than that of being impossible. Any calculation based upon absolute infinity, or upon any function whatever of absolute infinity, is itself absurd." The writer agrees with him in this, in part. When the results of two methods fail to agree, "look for the infinity" he says, and you will probably find the error.

When absolute infinity occurs, as it does, in mathematical deductions, there are two ways in which it can be safely applied in practise. The first one applies (as Fleury admits), when it is possible to assume that the quantity is simply so large (though finite) that others which depend on it may safely be taken as the same as they would be if it were infinitely large; this is often the case. For instance, in starting a current in circuits containing some small inductance, a few seconds is generally quite safely taken to be the equivalent of the eternity required theoretically for the current to reach its final value even in very accurate tests; the currents in even sensitive tests made in New York do not appreciably affect simultaneous researches made in Philadelphia, the 90-mile distance being practically infinite. Our atmosphere should extend theoretically to infinity, according to the laws of gases, yet beyond the relatively short distance of 50-60 miles there is not enough left to consider; the moon, sun, planets and stars encounter no friction in our atmosphere, even though it should extend theoretically to infinity.

The second one applies when some *property* of an infinite quantity can be found which is finite and therefore can be practically applied; thus the 760-mm. pressure of our atmosphere is finite, though according to the theory of gases, the atmosphere must extend to infinity; or similarly, the radial magnetic pressure on the surface of a single straight conductor, by the flux surrounding it, is known to be finite, although the flux, like the atmosphere, should extend theoretically to infinity. It will be shown later that under certain conditions the flux energy is also finite, though the flux is infinite.

One of the pitfalls in dealing with infinities obtained mathematically is that sometimes the real result is that the quantity is merely indeterminate and not infinite; this may arise when a factor has been suppressed or dropped because it is unity, but it is physically still present.

By treating the circle as a special case of a straight line, instead of the reverse, infinities and their pitfalls are avoided, which is another reason for preferring to start with the straight line as the fundamental.

The Single Conductor

In dealing with the single straight conductor as the fundamental, the real underlying condition (besides the straightness of a reasonable length) is not that it must be infinitely long, but merely that the unit length is assumed be so far removed from all other currents, or magnets, that they will have no appreciable effect on it; such currents include its own return circuit. Hence in a complete circuit in the form of a large square the sides may be made so large that a unit length *l*, Fig. 1, in the middle of a side, is no longer affected by the return current in the opposite side *L*.

The only three effects which neighboring currents can have on the unit length *l*, are attraction, repulsion and induction, which decrease as the square of the distance, and although they may also increase as the length *L* increases, yet the action of both combined is always a *decreasing* function, hence a distance may always be reached at which the effects are small enough to be neglected, as is always done when two or more independent tests with complete circuits are made at different places at the same time, even though with great accuracy.

Hence such a square can always be conceived in which the field at its center may safely be taken as

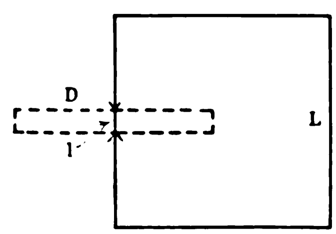

Fig. 1

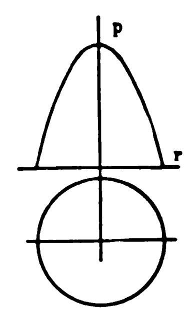

Fig. 2

zero, and therefore a unit length *l* in the middle of a side is practically as free from the effects of neighboring currents, as though it were a single conductor, and the flux and flux energy inherent with it are practically those in the disk-shaped space *D* between two parallel planes one unit apart, just as they are in a single conductor. Such a unit length *l* may therefore be taken to represent a unit length of a single conductor to any degree of accuracy desired by merely making the square large enough. Such a square circuit is therefore a connecting link between a unit length of a single, straight, conductor and a complete circuit; and the condition of infinite length, so often used in order to degenerate the single conductor to the realm of impossibilities, is no longer justifiable; some of the pitfalls of infinity are thereby avoided.

Maxwell himself determined (Art. 478) the now classic law for the flux density around a single conductor, with such a closed circuit; Northrup's determination of the internal pressures in a single conductor produced by the flux, is not based on the condition of infinite length, but as he says, merely on freedom from the effects of neighboring currents, and the accuracy of his expression was checked experimentally in a

2. This was well brought out in a discussion by Dr. C. O. Mailloux, Trans. A. I. E. E., Vol. 42, 1923, p. 328, Col. 2, par. 4, to p. 329, Col. 2, par. 2.

closed circuit. Ampere's able analytical researches with the single conductor were no doubt based on the same conditions; so is the generally accepted $i^2/4$ energy of the flux in the interior of a conductor. Many other like cases could be cited, showing that the infinite length is not a necessary condition. The same condition of freedom from all external influences is assumed in all accurate electrical tests, hence it is not an unreasonable or impossible condition.

Energy

Energy is the one physical quantity which is common to all physical phenomena and processes, and its absolute unit, the erg, applies to them all; hence it is the best and in fact the only connecting link between all the different groups of physical phenomena. Forces may be electromotive, magnetomotive, or ponderomotive (tending to move masses), each of which is physically different from the other, and their units are different and are not directly convertible. Moreover some forces are vector quantities, have components and resultants, can be generated or annulled and follow different laws, while energy is always a constant quantity no matter what form it may be in and its laws are common to all its forms. Energy is therefore the best physical quantity to use as a fundamental and the best connecting link between different physical phenomena.

Zero Resistance

In searching for fundamentals the number of factors or variables should of course be the least possible. At absolute zero of temperature the resistance of pure metals is eliminated, as it is zero; a current once started, as by induction, will therefore continue (theoretically) to flow forever, just as a body set into motion will continue to move when it meets with no resistance. Zero resistance will be assumed in the present discussion.

In the electric case this stored energy, which was stored while the current was started, is represented entirely by what seem to be stresses or strains of the ambient ether, which are called magnetism, hence it is magnetic energy and seems to be very closely analogous to the mechanical stresses or strains in compressed or stretched elastic rubber, and is static or potential in its nature. This stored energy of a current is closely analogous to the $m\,v^2/2$ energy stored in a moving body. When any of this stored energy, at zero resistance, is released, as by doing external work, the current also decreases, as shown in a paper by the writer,[3] and when it has all been released the current will become zero.

Such a condition of zero resistance simplifies greatly the considerations and conception of some electrical phenomena involving flux and energy, as there is then no external source of energy to mask the conditions when some of the stored energy has been released, as is the case when a "constant current" is specified in stating the laws, as it usually is, in which case the released energy is at once restored again, and there is also a continuous flow of energy. At zero resistance and with no connected source, the variables are reduced to their minimum, hence they are the best conditions for studying the fundamentals. The permeability is, of course, assumed to be unity, in all such fundamentals.

Unit Relations

The very basis of the absolute or c.g.s. system is to make as many as possible of the numerical relations between different fundamental physical quantities, unit relations, that is, the coefficient is unity, in which, however, the factor 2 often resulting from integrations, and π which cannot be avoided, must be included. If therefore, in the search for new fundamentals and relations between them, the latter turn out to be unit relations, the presumption is strong that they are correct, though it is not necessarily an absolute proof. A number of the relations deduced below will be seen to be unit relations.

The Fundamental Constant

One of the most basic fundamental quantities in electrodynamics therefore seems to be the energy represented by, or inherent with, or stored in, a unit length of single, straight conductor by a given steady current, under the most basic conditions; if this quantity leads to unit relations its fundamental character is confirmed.

Determination of this Constant. The problem which the writer endeavored to solve therefore was to determine this basic fundamental constant and to do so by a method which does not involve any physical quantities other than energy, mechanical forces, and currents, hence excluding completely that ambiguous quantity called self-inductance, and the theory of linkages (perhaps still incompletely proved) in the case of self-produced flux, both of which are so often relied upon absolutely in such energy calculations; nor does it involve any infinities or "postulates"[4] and it is moreover very direct and simple; there should, therefore, be no difficulty in either confirming it or pointing out precisely the error in it, if there is one. This energy should of course be the same no matter by which process it has been determined; if not, an explanation must be looked for and it ought to be possible to find it, especially if it lies in this simple proof. Fleury's advice in such cases is to "look for the infinity." While this method is new and different from the orthodox ones, it involves no new or unproven laws.

The method is based on the recently discovered and now well-known fact that when a current passes through a conductor internal stresses and strains in the form of radial pressures and longitudinal tensile stresses are produced, quite analogous to those in a magnetic field;

3. Trans. A. I. E. E. Vol. 42, 1923, p. 325.

4. A postulate is defined in the dictionary as "a proposition accepted *without proof;* something that must be *assumed* in order to account for something else." (Italics are the author's.)

but as the former act directly to tend to move the material of the conductor, they produce truly ponderomotive forces (tending to move masses), as is readily shown when the conductors are liquid and the current is large enough, as they increase with the square of the current, like most other electromagnetic forces. Being true mechanical forces they can be correctly specified and measured in dynes. Hence by letting these known mechanical forces act through known distances, the corresponding amounts of energy may be determined. Unfortunately neither Ampere nor Maxwell had the advantage of any knowledge of these internal stresses.

Internal Stresses

Many years ago the writer noticed these stresses when large currents were passed through liquid conductors in electric furnaces; the forces were sometimes strong enough to completely rupture the circuit by crushing it radially or tearing it longitudinally, and as this always occurred in one place by depressing the liquid where the cross section of the open channel happened to be least, the phenomenon was colloquially called the "pinch effect" by which term it is now generally known. These forces are now used very effectively in hundreds of electric furnaces for lifting and circulating the liquid metal.

Later, Dr. E. F. Northrup, to whom the writer had described this peculiar phenomenon, developed the mathematical formula for the quantitative value of these pressures, in a very able paper.[5] He based it on the attraction of the filamentary conductors for each other, and also on the radial force acting on each filamentary conductor due to its being in the magnetic field inside of the conductor; both methods gave the same result. It is important to note that it was also confirmed by him later experimentally to a high degree of accuracy (using, of course, a complete circuit), showing that the pressures were true, mechanical ones, and that their units in the formula are in dynes per sq. cm. This formula or law may therefore be safely accepted as quantitatively correct, reliable and accurate. The present writer showed later that in the c. g. s. system this law is a *unit relation* for the pressure at the center of a round conductor which, though it may not be a proof, is always strongly confirmatory of correctness. This easily remembered relation is $p = i^2 / S$ in which S is the section.

Northrup's general law for the radial pressure p in dynes per square centimeter at any point in the interior of a round conductor of radius R at a radial distance r from the center, and carrying a current i, is $p = i^2 (R^2 - r^2) \div \pi R^4$, the now well-known "pinch" pressure formula; all the quantities are in c. g. s. units. This gives the *mechanical* stresses or strains in the form of radial pressures in any part of the cross section of a round conductor, produced by a current flowing through it. The curve of these pressures is a parabola, Fig. 2; hence for the whole section the curved surface of the loci is a paraboloid of revolution. This mechanical pressure is zero at the circumference, a maximum at the center, and the mean over the whole section can readily be shown to be half of the maximum; the formula also shows that this radial pressure is independent of the length of the conductor. This formula is based on the condition that, as Northrup himself states it, the conductor is a part of a very long straight conductor of circular section "very far separated from its return conductor," hence is not limited to the impossible infinitely long conductor.

5. *Physical Review*, June 1907, p. 474.

Proofs

There are several proofs of this constant, $i^2/2$ ergs per cm. all of which lead to the same result and therefore confirm each other. They are rigid, being free from approximations, dropped factors, infinities, inductance, self-inductances, or mere postulates. One is based on the radial pressures, one on the longitudinal force, and other shorter ones based on what some may consider allowable assumptions. The energy referred to is that which is required to start a steady current; it is constant while the current is flowing, and is set free again when the current stops; it is quite independent of the energy which may be transmitted while the current is flowing; it is quite analogous to the vis viva or the $m\,v^2/2$ energy in a moving body, like that required to bring the cable itself up to its normal speed in a cable transmission. By the first method, based on the radial pressures, it is measured as it is set free, while the current decreases to zero; it involves only two of Maxwell's undisputed laws. By the second method, based on the longitudinal force, it is measured as it is being stored by a constant current in an increased length of the conductor; it involves only the Northrup and the so-called Kelvin laws. In both, the conductor is assumed to be a liquid, and the energy is measured by the mechanical work done by this energy.

Radial Pressure Method. A steady current is assumed to have been started by an external source, in a circuit of zero resistance, hence would continue to flow without a connected source until all its vis viva or stored energy has been consumed by transformation into some other form of energy. This stored energy is quite analogous to the $m\,v^2/2$ energy stored in a body moving at a constant velocity and without encountering any resistance.

An experimental proof that the energy stored in a body moving at a constant velocity is equal to that given by the well-known formula $m\,v^2/2$, might be obtained by opposing the motion of that body by a *constant* pressure or force until it comes to rest, when its energy is exhausted; then the product of this force and the distance over which it was applied before the body came to rest, would evidently be equal to this

$m\,v^2/2$ energy, thereby proving that this expression gives the correct amount, or that this amount might be determined in that way if that formula were unknown.

The present method is quite similar. Assume any given length l of such a straight, single, liquid conductor of circular section having a radius R and a current I (c. g. s. units); or it may be the whole circuit of length l, if only it is large enough that each unit length is far enough from the return circuit not to be affected by it. It is well known and could easily be shown, that such a liquid conductor will tend to shrink radially, due to the pressures produced by this stored magnetic energy.

From Maxwell's $H = 2\,I/R$ for such single conductors, and his $H^2/8\pi$ pressure formula, this radial magnetic pressure on the outside surface is easily shown to be $I^2/2\pi\,R^2$ in dynes per sq. cm.; this is the total, *resultant*, pressure; it will be explained below why this is the resultant and under what conditions Maxwell's $H^2/8\,\pi$ pressures are true mechanical pressures in dynes per sq. cm. Whatever may be the detailed explanation of the mechanism of this shrinkage, say through a radial distance d, it is true in any case that this pressure must have then acted through this distance d and has thereby done work. Let the outflow of this liquid due to this shrinkage be assumed to be opposed by a constant mechanical pressure on the liquid (analogously to the constant pressure referred to above opposing a moving body), as for instance by making the liquid which is ejected by this shrinkage raise a weight, as it does in hundreds of electrical furnaces in daily use.[6] This opposing constant outflow pressure is made equal to the above radial pressure.

In thus acting on the outside through the distance d this constant radial pressure has set free a known part of the energy originally stored in the flux; this is determined from the distance d and the known force, equal to this constant pressure multiplied by the mean area. Hence there is then left less flux energy and therefore of course also less current. Let this shrinkage at constant outside pressure against an equal, constant, outflow pressure, continue until the conductor has shrunk to a line, that is, to zero.

At these radial and outflow pressures, assumed to be constant and equal, it can be shown that $I^2/i^2 = R^2/r^2$ in which i and r are the current and radius after a shrinkage; for the first pressure P is $I^2/2\,\pi\,R^2$ and the pressure p after this shrinkage to a radius r is $i^2/2\,\pi\,r^2$; when these are made equal to each other the above relation follows. Hence $I/i = R/r$, that is, the currents will diminish in proportion to the radius, and therefore the current, and with it of course the energy also, will become zero, when the radius has shrunk to zero. This shows that *all* the stored energy has thus been consumed in crushing the conductor to zero. The remaining energies are proportional to the squares of the currents or radii, but this is not an essential relation in this proof.

It also follows that for any given length l of the conductor the total radial *force*, as distinguished from pressure (force = pressure $\times$ area), diminishes in proportion to the radius, that is, $F/f = R/r$ and it is therefore also zero when the radius is zero. These simple relations hold only when the outflow pressure is made numerically equal to this constant radial pressure; this outflow pressure always exists at a distance from the center equal to the outside radius divided by the square root of 2, as shown by the Northrup formula. and his experimental demonstrations show that these forces are true, mechanical forces in dynes agreeing quantitatively with Maxwell's formulas.

As the original radial pressure is $P = I^2\,2\,\pi\,R^2$ the force at first is $F = 2\,\pi\,R\,P\,l = l\,I^2/R$ in dynes, and as it diminishes in proportion to the radius, the work done by its acting radially to the center is the mean of the original and zero, hence is $l\,I^2/2\,R$, which acting through the distance R gives as the original stored energy $W = l\,I^2/2$ ergs or $I^2/2$ ergs per cm., *which is the basic, fundamental constant sought for.* This quantity was thought by our forefathers to be infinity, as deduced from the "complete circuit" system; the explanation why there is this disagreement will be given below. Attention is called to the fact that this total $i^2/2$ ergs, is just twice that long known to reside in the inside of the conductor.

The same result could be obtained by the calculus, and the liquid might then be assumed to be ejected continuously at the center where the pressure will vary from twice the radial pressure at the start, to zero at the end; the opposing outflow pressure must then be assumed to vary accordingly in order that at every moment there is equilibrium. The radial pressures will then no longer be constant but will decrease, and the current will decrease faster than in proportion to the radius. It is then analogous to stopping the movement of a body by means of a variable, instead of a constant, force.

Longitudinal Force Method. A steady current is assumed to be kept flowing in a liquid conductor of zero resistance, zero weight, and constant diameter, by a continuously applied source. Instead of allowing the mechanical stress to act radially to set free the stored

6. If necessary to picture the details (though they are immaterial and do not affect the theory involved) let the liquid be supposed to be ejected through a tube leading to a cylinder foreign to the conductor, having a piston which raises a constant weight; as the pressures in the interior of the conductor are known to be different at different distances from the center, this tube is assumed to be applied at that radial distance r from the center (namely when $r^2 = R^2/2$) at which this particular pressure exists and is constant during the shrinkage, hence it must be assumed to be moved toward the center as the conductor shrinks. When this is done, and only under those conditions, the quantitative mathematical relations become extremely simple, as will be shown. This shrinkage against an opposing pressure must of course be assumed to take place simultaneously throughout the whole of that circuit, though only a portion of it needs to be considered mathematically.

energy as before, it is now allowed to act longitudinally to lengthen the conductor of constant diameter by a specified amount, whereby the source adds to the circuit the energy stored in this added length. This added energy is calculated by letting this known longitudinal force lift a known weight through a known height while lengthening the conductor by the latter distance; the source thereby does a known amount of external work, and according to the so-called Kelvin law it then simultanously adds to the stored energy of the circuit an amount equal to the external work done. Hence the energy stored in this added length is equal to this known external work done.

The force is calculated from the pressures given by the Northrup law, which is generally recognized as correct, both relatively and quantitatively, and the pressures have been shown experimentally to be true mechanical pressures in dynes per sq. cm.; it may now be safely classed under the "classic" laws. The

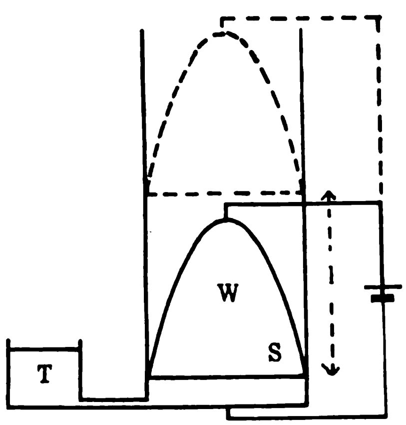

Fig. 3

Kelvin law, though not always referred to by this name, seems to be a universal law in dynamics and when properly worded, may also be safely classed under the "classic" laws. The conditions of the circuit are that only the additional length need be liquid, the parts near it must have the same diameter, the part that moves must be considered as weightless and of course it must be straight for a reasonable length and the return circuit must be far removed.

In Fig. 3, let S be conceived to represent an infinitely thin cross sectional layer of a circular, liquid, conductor of radius R. Let W be a weight, which may be shaped as a paraboloid of revolution to correspond with the pressure loci in Fig. 2, though merely to simplify the conception, as a cylindrical body of half the maximum height and the same base, would have the same weight or volume and would answer quite as well. Let a current i be conceived to be passed axially through this section, the rest of the circuit being shown diagrammatically only. Let the layer S be assumed to be connected at its circumference, where the pressure is zero, to a supply reservoir of more liquid diagrammatically represented by T; the liquid is assumed to be weightless and the supply from the outside is assumed to exert no pressure and to involve no energy.

The conductor S being a liquid the radial pressures of the Northrup formula will act equally well axially, let it be said by hydraulic action, if that is preferred; hence they will raise the weight W, the additional weightless liquid necessary to provide for the lengthening of the conductor, being supposed to be supplied from the outside under no pressure. The pressure formula will be seen to be independent of the axial length, hence these axial pressures will always remain the same as the weight is raised, that is, the total vertical lifting force is a constant, for a constant current. This axial lifting force is being used in hundreds of electrical furnaces in daily use lifting many tons per day, hence is well known and not a mere theoretical force on paper; its quantitative value is also well known.

Let the weight be lifted l cm. (Fig. 3). The surface of the loci of the pressures being a paraboloid of revolution, it can readily be shown[7] that the average pressure over the whole section is half the maximum at the axis. At the axis $r = 0$ (in the Northrup formula), hence the maximum pressure there is $p = i^2/\pi R^2$; multiplying half of this by the total area πR^2, gives $i^2/2$ as the force in dynes; that is, the total lifting force, and therefore the weight W which it will lift, is numerically equal to $i^2/2$ dynes. Having lifted it l cm. the external energy expended on the weight is: energy = force $\times$ distance = $l\, i^2/2$ or $i^2/2$ ergs per unit length. Hence according to the above mentioned Kelvin law, the stored magnetic energy of the conductor per centimeter of length, must be $i^2/2$ ergs also, the source having supplied double this energy. *This is the basic fundamental constant sought for.*

Other proofs. A given radial pressure can always be replaced by its corresponding circumferential tension. If P is the radial pressure on the outside of a conductor as given above, it can be shown that the tensional force (not pressure) in a band encircling a unit length of the conductor and producing the same radial pressure, is $P\,R$ in dynes, in which R is the radius. If a stretched, elastic band, having this tension be assumed to be developed into a straight line (equal to the circumference) and then allowed to shrink to zero length, following the law of the perfect spring, namely that the tension is proportional to its length, it can be shown that the energy set free thereby is again the same, $i^2/2$ ergs.

From the Northrup formula the pressure in dynes per sq. cm. at the center is just twice the $i^2/2\,\pi R^2$ pressure in the same units, at the periphery, from outside. As the outside pressure must also act at the center, it might be argued that the inside flux has added an equal amount, hence that the energies residing inside and

7. It is well known that the volume or weight of such a paraboloid of revolution is equal to that of a cylinder having the same base and half the height.

outside are equal, therefore the total is double the well known inside energy $i^2/4$.

At the periphery the two mechanical forces balance, as there is no tendency to movement there, according to the Northrup formula; there is no resultant there. As the forces are equal the energies should be also, as both forces must be considered relatively to the same center, hence as acting through the same distance, the radius. Again the total is twice that inside.

The very basis of the c. g. s. system is that the fundamental relations are unit relations, at least as far as possible. If it may therefore be assumed that the self-inductance (in its true, energy sense) of a unit length of the fundamental conductor, is unity, then if L in the usual expression $L\,i^2/2$ for this energy, is made unity, the energy becomes $i^2/2$. A self-inductance is stated to be physically a length, and in the c. g. s. system it is correctly measured in centimeters. Under fundamental conditions this length and the length of the conductor should be the same thing. This constant then follows directly.

Those who recognize the existence of the longitudinal force, will find that in a fundamental conductor of uniform diameter it is numerically equal to $i^2/2$ dynes, from the Northrup formula, and that in this fundamental conductor it is independent of the diameter or the length. Hence when this force acts to stretch or lengthen its conductor without doing any external work, (though generating a counter e. m. f.) the energy is being stored, just as it would be when the speed of a moving body is increased. If l is this added length, the added energy will of course be $l\,i^2/2$ ergs, which for a unit length again gives $i^2/2$.

Doubtless still more proofs could be found which are also free from the pitfalls of infinities, the ambiguous self-inductances, and the short comings of the complete circuit theories, which had misled us in the past.

Deductions from this Constant

It will be seen that this constant is independent of the diameter of the wire, and depends only on the current, both of which have long been known to be true of the flux energy residing in the interior of the conductor, $i^2/4$. For any length l the energy is $l\,i^2/2$, that is, it is directly proportional to the length. This $i^2/2$ ergs is apparently one of the most basic fundamental constants in electrodynamics, and from it interesting deductions follow.

This $i^2/2$ is the total stored energy, outside of the wire and inside. It has long been known and is easily proved, that the amount stored inside of the conductor is $i^2/4$ ergs per cm. It follows therefore that of the total, half of the energy resides in the inside and half on the outside, as one might expect nature to distribute it.

This constant also shows that the energy of the flux is finite, though the flux itself is of infinite extent, in the same sense that our atmosphere extends to infinity. It is one of those cases in which a *property* of an infinite quantity is finite and therefore affords a means of treating an infinite quantity mathematically without danger of falling into the pitfalls of mathematical infinity. Another finite property of this theoretically infinite flux is what might, in a certain sense, be called the resultant or equivalent flux, as will be described below.

Reduced to the units used in practise the general formula becomes $W = 0.00001524\ l\,I^2$ in which W is the stored energy in watt-seconds or joules, l is the length in 1000-ft. units, and I is the current in amperes. This shows how extremely small it is.

A very interesting and important deduction, showing another new unit relation, is that in the c. g. s. system each unit of current generates one unit of flux around such a conductor, in each unit of length, and independent of the diameter; it includes all the flux inside and outside. But this flux must be specifically defined, as it is a resultant, equivalent, or condensation of all the very large number of lines into which it divides itself as it spreads out into space; these resultant lines might be termed fundamental maxwells. This condensation is such that these resultant lines when combined with the magnetomotive force in common to them all, represent the true stored energy in that field. It is somewhat analogous to supposing our widely diffused atmosphere to be condensed into a thin solid or liquid layer around the earth, which has the same mass. Or these condensed lines may be imagined to be those originally generated by the current and then spread out into space according to the laws of distribution, *but without any change of energy contents*, just as the condensed atmosphere would spread out without change of mass. Such lines are a means of summing up an infinite quantity by one of its properties (energy in this case) to get something finite. They are useful in calculations of flux energy and they clear up some ambiguities, but they are sometimes distinctly different from those entering into calculations of the induction of e. m. fs. by cutting or linking. This will be further discussed below.

The proof of this equality is as follows. The energy residing in a complete circuit of flux is: ergs = maxwells × gilberts/$8\,\pi$. The magnetomotive force in gilberts around a single conductor is $4\,\pi\,i$, and as the energy per unit of length is $i^2/2$, it follows that $i^2/2 = 4\,\pi\,i\,f/8\,\pi$ in which f is the number of lines in maxwells; hence $i = f$. This unit relation is a fundamental one and applies rigidly only to the fundamental conductor, and of course, not at all to bi-filar non-inductive circuits, nor when the permeability is not unity. The "complete circuit" mathematics leads us away from it rather than toward it. It seems to mean that in the c. g. s. system current and flux are merely different physical representations of the same quantity, as far as energy is concerned, though, of course, only when the resistance energy is zero; or that magnetism

is merely an effect of current at a distance, the energy residing in the moving electrons.

For a unit length and unit radius the total radial force (not pressure) from the outside, is numerically equal to i^2 dynes, hence is another unit relation; for other radii it is inversely proportional to the radius. This force multiplied by half the radius (because it is radial) again gives the constant $i^2/2$.

The stored magnetic energy in any part of a circuit is generally calculated from the formula $L\,i^2/2$ in which L is the self-inductance of that part in centimeters. In the fundamental conductor this energy is $l\,i^2/2$ in which l is the length in centimeters. Hence in such conductors the self-inductance (in the energy sense of that term) is the same thing as the length of the circuit, that is, the distance over which the current flows; another interesting unit relation. This explains why a self-inductance is physically the same kind of a quantity as a length, a purely geometric quantity, at least under the most fundamental conditions; the permeability is of course taken to be unity in all fundamental cases. It also shows why in the c. g. s. system it is correctly expressed in centimeters, or in 10,000. kilometers for the henry. It also follows that under these fundamental conditions the self-inductance is independent of the diameter of the wire, which would seem to follow also from the long-known fact that the energy of the flux in the interior of the wire is independent of the diameter.

This stored electromagnetic energy, $l\,i^2/2$ of a current is quite analogous to the visviva or stored mass energy $m\,v^2/2$ of a moving body. In the c. g. s. system both are equal to ½ erg when all the quantities are unity, and one may write $l\,i^2 = m\,v^2$, which means that if all the electromagnetic energy stored by a current i flowing for a distance l, in such a single conductor, be converted into moving mass energy, the relation of the mass to the velocity must be such that $m\,v^2 = l\,i^2$. Thus for say 1000 amperes flowing in such a conductor, the stored electromagnetic energy in every foot, is the same as the mechanical energy stored in a weight of 0.723 or nearly ¾ lb. moving at 1 ft. per sec., or 0.181 lb. at 2 ft. per sec.; all are equal to 0.01124 foot-pounds or 152,400 ergs. This is the energy, per foot of conductor, set free when the current is stopped. For any other length of conductor this equivalent mass increases as this length.

It is of interest to note that for 1 ampere this energy stored per centimeter is equal to that of 5.10 millionths of a gram raised one centimeter, which is extremely small, and shows why the least resistance in such a conductor stops a current almost instantly after the e. m. f. ceases. Yet our forefathers claimed that this energy was infinitely large, which it seems is still being taught.

Another result which this constant, $i^2/2$, has led to, is a better understanding of the true nature of flux energy and calculations pertaining to it, as explained below.

Disagreement

When this stored magnetic energy per unit length of a single conductor is deduced by means of the mathematics of the complete circuit and by some of the older methods and postulates, or by means of self-inductance formulas (always only approximate), the result is that even for a very small current this stored energy per unit length is infinite, while $i^2/2$ is generally quite small. But as the above proofs are simple, brief, rigid, and involve nothing but well established laws, it does not seem possible to find any error in them in a long discussion since the writer's first publication of this result,[8] deduced by a similar though more involved process.

The discrepancy therefore must be looked for elsewhere. The mere fact that the result differs from our older views, cannot of course, be accepted as a proof of an error in it; if that were done in this and other cases, further progress in science would be checked.

The writer believes that this discrepancy can best be located and explained, and that the criticisms of the above proofs can best be answered, by first getting a clearer conception of the various factors and elements involved, and by endeavoring to show how and where some of our older conceptions had misled us, and which of them may be questioned and should be modified or revised if wrong. The new result, if correct, may well be used as a test of the correctness of some of the older laws and postulates.

These explanations are discussed in detail in the complete pamphlet copies of this paper; the following is merely a very brief synopsis. If in the large square circuit Fig. 4, the lengthening (in the second one of the proofs) takes place in both of two opposite sides, the only new flux will be in the parts D, D, and that in the rest of the circuit will not have been changed in the least. This answers some criticisms concerning the "rest of the circuit." If instead, such a circuit be

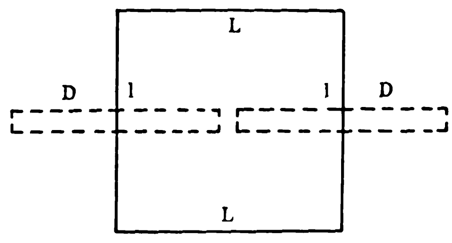

Fig. 4

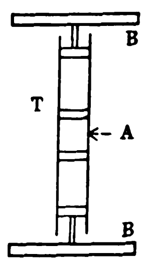

Fig. 5

forced to be shortened slightly instead of lengthened, it must set free an infinite amount of energy, according to the ideas of our forefathers; but this is evidently absurd.

Fig. 5 illustrates the same principle as that involved in lengthening a rope supporting a weight; the force in this additional past must not be added to that in the rest as it is the same force. This answers a criticism.

8. A Single Straight Conductor as a New Fundamental. *Jour. Frank. Inst.*, Feb. 1925, p. 235. In this article the first part of the paragraph forming the upper half of p. 243 contains an unfortunate arithmetical error and should be deleted.

In Fig. 6, if C is the cross section of a conductor the curve F gives the density H outside of the wire, and f that inside; at the surface they are both equal to h. The flux lines outside act by their contraction like layers of stretched rubber bands over each other; hence the radial pressure at the surface is the *resultant* of all those radially beyond; just as the 760 mm. pressure of our atmosphere is the resultant of those of all the layers above. In either case it would be wrong to add to this resultant (as by integration) the pressures of its component parts beyond; or to add the energies based on these pressures, yet this has been done by our forefathers. This is claimed to have been the chief cause of the disagreement.[9] Zero resistance should be assumed in such cases, as energies which are set free are then not continuously being restored. Although the outside and inside flux pressures balance each other at the surface where they are h, it is explained how the outer one will act when the inner mechanical pressure is reduced.

In Fig. 7 C is the section of a very thick walled rubber tube, expanded by a compressed liquid h. The stresses, strains and stored energy in this rubber wall are then closely analogous to those in a magnetic field around a conductor h. In both, the radial pressures on h are the *resultants* of all those radially beyond, which must therefore not be added to them; the energy stored in the rubber is finite, and could be measured by allowing the liquid to be ejected under pressure, as in the first of the above proofs. Flux lines exist in the space around the wire, but if the energy of the whole field has been determined from their resultant at the surface, those beyond must be considered as wattless, in the sense that their energies have already been accounted for in their resultant and must therefore not be added to it again. It is shown that the e. m. f. induced by cutting or linking of lines is independent of the energy residing in those lines, which may therefore be wattless in the above sense; hence the energies in such lines cannot be deduced from the e. m. f. induced.

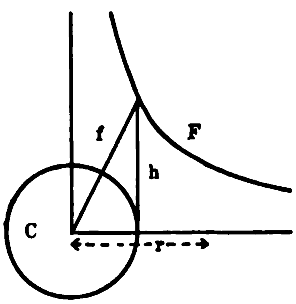

Fig. 6

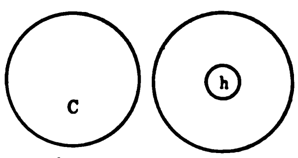

Fig. 7

It is shown that Maxwell's $H^2/8\pi$ pressures are true mechanical pressures in dynes per sq. cm. when properly interpreted. This expression seems to apply correctly only to uniform fields, hence not to those with curved lines, as in these some of the pressures are the resultants of others; or it may be applied to differentially small parts, but can then not always be added together by integration. The lack of consideration of the abutments of the forces, has led to confusion; they do not appear in calculus calculations and are often overlooked. The ether cannot act as an abutment for mechanical forces. The abutment of the encircling flux is the surface of the wire.

The propriety of using the term self-inductance in both of its two different senses (inducing e. m. fs. and determining the stored energy) is questioned. It is shown that the error of adding the energy of components to that of their resultant, enters. As all self-inductance formulas are only approximate, extrapolating them to infinity is not rational, yet it has been done. Self-inductance is generally defined as a derived quantity, flux per ampere, yet physically it is a mere geometric, independent quantity, a length, hence independent of either flux or current. That ratio may sometimes lead to errors when some of the flux should be considered as wattless just as a resistance defined as the quotient of volts divided by amperes, may lead to errors when some of the amperes are wattless. Reforms in the true meaning of the term self-inductance are recommended and reasons are given.

The error arising from adding components to their resultant, seems to be greatest for very large single turn circuits, and small for the coils used in practise; still less when iron is used, as is usual. It affects theory, especially basic fundamentals, rather than practise. Attention is called to the much discussed longitudinal force and its evident existance in this investigation; its value is given.

Conclusions

In the opinion of the writer, the above proofs, deductions, and discussion, will show that a new system of treatment of electrical problems can be based on the single, straight, conductor, as distinguished from that based on the Maxwell complete circuit; not to replace the latter system but to supplement it, and to test the correctness of parts of it. The single conductor system leads to some new and useful results and shows that we should modify some of our former conceptions; also that in flux lines there is an analogy to the wattless ampere which ought to be recognized. It also shows that the term self-inductance has been used in a dual sense and that a distinction should be made analogous to that between resistance and reactance. Some heretofore unknown and useful relations have been deduced from what is believed to be one of the most fundamental constants in electrodynamics, the value of which is determined by simple proofs. Some of the results deduced could not have been deduced from the complete circuit system, which has, in some cases, been misleading.

9. This is also discussed in an article by the writer on Magnetic Flux Energy, in the *Jour.* Frank. Inst., Dec. 1925, p. 747.

Parameters of Heating Curves of Electrical Machinery

BY VLADIMIR KARAPETOFF[1]
Fellow, A. I. E. E.

Synopsis.— *When a body is being heated by a uniform addition of a constant quantity of heat per unit time, its temperature above the ambient air (the latter being assumed to remain at a constant temperature) increases approximately according to an exponential law. The exponent is proportional to the ratio between the heat capacity of the body and the coefficient of thermal dissipation into the surrounding medium. In a paper read before the Institute's Midwinter Convention, 1925,* (JOURNAL, *Vol. 44, p. 142) Doctor A. E. Kennelly has proposed to include such a coefficient among other characteristics of an electrical machine. In the present paper it is pointed out that for thermal purposes an electrical machine cannot be considered as a single body, since the stator consists of two metal bodies (the winding and the core) between which there may be a considerable heat interchange, and that the rotor is also such a composite body. Differential equations of heat flow in a combinational body are established and solved. The stator winding is thermally determined by its heat capacity and its heat dissipation coefficient, and so is the stator core; further, there is a coefficient of mutual flow. The rotor also requires five similar coefficients. Thus, while an electrical machine could be defined by its thermal coefficients, and the temperature rise of the different parts predicted for a given operating regime, the number of required parameters is much larger than for a single body.*

• • • • •

WHEN an attempt is made to represent, analytically, the temperature rise with the time in an electrical machine at constant losses, the time-temperature curve is usually assumed to be exponential.[2] Recently, Dr. A. E. Kennelly has extended the treatment and has shown that the curve remains exponential even when the losses themselves are linear functions of the temperature.[3]

Actual heating curves sometimes differ materially from the simple exponential form. This can be shown by plotting the differences between the ultimate temperature and the instantaneous temperatures against time as abscissas, on semi-log paper. An exponential curve should give a straight line, and this is not always the case. The principal reason for this discrepancy is that the stator of a machine cannot be considered as one "chunk" of metal; it consists of two metal bodies, the winding and the core, between which there may be an appreciable difference of temperatures. The same is true of the rotor. In a transformer, three separate metal bodies at different temperatures may be distinguished.

It is the purpose of the following investigation to show that with two metal bodies at different temperatures, and with heat interchange between them through a layer of insulation, the heating curve for each consists of two exponential terms with different exponents. Thus, each part of a machine should be characterized by at least two composite thermal time constants, and these will represent an experimental heating curve much more closely than is possible with one thermal time constant and with a common curve for both the winding and the core.

Doctor Kennelly compares the transient period of temperature rise to a transient rise of current in a d-c. circuit containing a resistance r and an inductance L. In the latter case, the rise in current is also exponential and depends upon the time constant (L/r) of the circuit. However, a stator, or a rotor, is more nearly analogous to a system of two coupled electric circuits, in which the current rise is represented by two or more exponential terms, each with a different time constant[4].

With the notation given at the end of the paper[5],

$$p_1\, d\, t = \theta_1\,(s_1 - s_{12})\, d\, t + (\theta_1 - \theta_2)\, s_{12}\, d\, t + k_1\, d\, \theta_1 \quad (1)$$

$$(\theta_1 - \theta_2)\, s_{12}\, d\, t + p_2\, d\, t = \theta_2\,(s_2 - s_{12})\, d\, t + k_2\, d\, \theta_2 \quad (2)$$

These equations are similar to Doctor Kennelly's equation (**19**), and refer to the metal Parts 1 and 2 of one of the principal members of the machine respectively,— say the stator winding and the stator core. Equation (**1**) expresses the fact that the heat $p_1\, d\, t$, developed in the part 1 during an infinitesimal element of time, $d\, t$, is used up in three ways: The part $\theta_1\,(s_1 - s_{12})\, d\, t$ is communicated to the ambient air or other cooling medium; the part $(\theta_1 - \theta_2)\, s_{12}\, d\, t$ is communicated to the Part 2 of the machine, and the remainder, $k_1\, d\, \theta_1$, raises the temperature of the Part 1 by $d\, \theta_1$. Equation (**2**) has a similar meaning for Part 2, with the term $(\theta_1 - \theta_2)\, s_{12}$ considered as part of the heat input.

Dividing throughout by $d\, t$, and introducing the "deficiencies", $\delta_1 = \theta_{10} - \theta_1$ and $\delta_2 = \theta_{20} - \theta_2$, in place of the temperatures themselves, equation (**1**) becomes,

$$p_1 = (\theta_{10} - \delta_1)\,(s_1 - s_{12}) + [(\theta_{10} - \delta_1) - (\theta_{20} - \delta_2)]\, s_{12} + k_1\, d\,(\theta_{10} - \delta_1)/d\, t \quad (3)$$

1. Professor of Electrical Engineering, Cornell University, Ithaca, N. Y.

2. For a theory of such simple heating curves see, for example, V. Karapetoff, *Experimental Electrical Engineering*, First Edition, 1909, p. 442.

3. A. E. Kennelly, *The Thermal Time Constants of Dynamo-Electric Machines*, A. I. E. E. JOURNAL, 1925, Vol. 44, p. 142.

To be presented at the Midwinter Convention of the A. I. E. E., New York, N. Y., Feb. 8-11, 1926.

4. G. W. Pierce, Electric Oscillations and Electric Waves, 1920, Chap. 7.

5. This notation is made to agree, as much as possible, with that in Dr. Kennelly's paper referred to above.

After the ultimate temperatures, θ_{10} and θ_{20}, have been reached,
we have, $\delta_1 = \delta_2 = 0$, and $d\,\delta_1/d\,t = 0$. Hence, for $t = \infty$, equation (3) becomes:

$$p_1 = \theta_{10}(s_1 - s_{12}) + (\theta_{10} - \theta_{20})\,s_{12} \qquad (4)$$

By analogy, equation (2) gives,

$$p_2 = \theta_{20}(s_2 - s_{12}) + (\theta_{20} - \theta_{10})\,s_{12} \qquad (5)$$

Substituting these values of p_1 and p_2 in equation (3) and in a similar equation obtained from equation (2), after reduction we get,

$$\delta_1 s_1 - \delta_2 s_{12} + k_1\,d\,\delta_1/d\,t = 0 \qquad (6)$$

$$\delta_2 s_2 - \delta_1 s_{12} + k_2\,d\,\delta_2/d\,t = 0 \qquad (7)$$

Equations (6) and (7) are simultaneous differential equations for δ_1 and δ_2, and their solution gives the desired expressions for the heating curves of the two metal parts of the stator or the rotor. To eliminate δ_2, differentiate equation (6) with respect to t. This gives,

$$s_1\,d\,\delta_1/d\,t - s_{12}\,d\,\delta_2/d\,t + k_1\,d^2\,\delta_1/d\,t^2 = 0 \qquad (8)$$

Multiply equation (6) by s_2, equation (7) by s_{12}, equation (8) by k_2, and add the three equations together. The variable δ_2 is then eliminated, and the result is

$$k_1 k_2\,d^2\,\delta_1/d\,t^2 + (k_1 s_2 + k_2 s_1)\,d\,\delta_1/d\,t + (s_1 s_2 - s_{12}^2)\,\delta_1 = 0 \qquad (9)$$

The solution of this equation is of the form

$$\delta_1 = A_1\,\epsilon^{-t/\sigma} + B_1\,\epsilon^{-t/\tau} \qquad (10)$$

where A_1 and B_1 are the constants of integration, and σ^{-1} and τ^{-1} are the roots of the "auxiliary" quadratic equation[6]

$$k_1 k_2\,x^2 - (k_1 s_2 + k_2 s_1)\,x + (s_1 s_2 - s_{12}^2) = 0 \qquad (11)$$

Solving this equation for x, gives

$$x = m \pm \sqrt{n^2 + q_1 q_2} \qquad (12)$$

where

$$m = 0.5\,[(s_1/k_1) + (s_2/k_2)] \qquad (13)$$

$$n = 0.5\,[(s_1/k_1) - (s_2/k_2)] \qquad (14)$$

$$q_1 = s_{12}/k_1\ ;\ q_2 = s_{12}/k_2 \qquad (15)$$

Let, for the sake of abbreviation,

$$r = \sqrt{n^2 + q_1 q_2} \qquad (16)$$

so that

$$q_1 q_2 = r^2 - n^2 \qquad (16a)$$

Since the thermal time constants, σ and τ, are the reciprocals of the two values of x in equation (12), we have,

$$\sigma^{-1} = m + r \qquad (17)$$

$$\tau^{-1} = m - r \qquad (18)$$

The subscripts of the coefficients in equation (9) are symmetrical with respect to 1 and 2. Hence, an identical equation may be written for δ_2, and the exponents σ and τ are the same for both δ_1 and δ_2. Thus, the general expression for δ_2 is:

$$\delta_2 = A_2\,\epsilon^{-t/\sigma} + B_2\,\epsilon^{-t/\tau} \qquad (19)$$

Substituting in equations (10) and (19) $t = 0$, gives

$$\theta_{10} = A_1 + B_1 \qquad (20)$$

$$\theta_{20} = A_2 + B_2 \qquad (21)$$

Substituting the values of δ_1 and δ_2 from equations (10) and (19) in equation (6), and equating separately the coefficients of $\epsilon^{-t/\sigma}$ and $\epsilon^{-t/\tau}$, gives the following two necessary relationships between A_1 and A_2, and between B_1 and B_2:

$$A_1(\sigma s_1 - k_1) = s_{12}\,\sigma A_2 \qquad (22)$$

$$B_1(\tau s_1 - k_1) = s_{12}\,\tau B_2 \qquad (23)$$

A substitution of the same values of δ_1 and δ_2 in equation (7) will give no new relationships between the above constants of integration. Solving equations (20) to (23) as simultaneous equations, and using equation (16a), we get:

$$A_1 = [(r + n)\,\theta_{10} - q_1\,\theta_{20}]/2\,r \qquad (24)$$

$$B_1 = [(r - n)\,\theta_{10} + q_1\,\theta_{20}]/2\,r \qquad (24)$$

$$A_2 = [(r - n)\,\theta_{20} - q_2\,\theta_{10}]/2\,r \qquad (26)$$

$$B_2 = [(r + n)\,\theta_{20} + q_2\,\theta_{10}]/2\,r \qquad (27)$$

These values are to be used in equations (10) and (19).

As a check on the foregoing expression, let, in a limiting case, the two hot bodies be entirely independent of each other: that is, put $s_{12} = 0$. Then $q_1 = q_2 = 0$; $r = n$; $\sigma^{-1} = s_1/k_1$; $\tau^{-1} = s_2/k_2$; $B_1 = A_2 = 0$; $A_1 = \theta_{10}$; $B_2 = \theta_{20}$.

Hence, equations (10) and (19) become:

$$\delta_1 = \theta_{10}\,\epsilon^{-t\,s_1/k_1};\ \delta_2 = \theta_{20}\,\epsilon^{-t\,s_2/k_2} \qquad (28)$$

which agrees with Doctor Kennelly's results for a single hot body.

If the losses themselves are functions of temperature, so that p_1, instead of being a constant, is, for example, a linear function of δ_1, the general form of equation (3) remains unchanged, although the coefficients will have a different meaning. The same is true of p_2. Hence, the general expressions for δ_1 and δ_2 will be of the same mathematical form as equations (10) and (19), only the coefficients and their interpretation will have to be deduced anew, following the general method used above.

Practical Application of the Above Formulas

In order to apply equations (10) and (19) to a given machine, it is necessary to determine the thermal dissipation coefficients s_1 and s_2, the heat transmission coefficient s_{12}, and the thermal capacities k_1 and k_2. As a concrete example, consider the stator of a synchronous machine, and let the subscript 1 refer to the winding and the subscript 2 to the iron core. Let the machine be run at a certain load until the constant ultimate temperatures, θ_{10} and θ_{20}, have been reached

6. See any text book on differential equations, chapter on linear equations with constant coefficients.

and measured. Let the values of the copper loss, p_1, and of the core loss, p_2, be also known. Then, equations (**4**) and (**5**) contain three unknown quantities, s_1, s_2, and s_{12}. Let a heat run be made also at some different values of the losses, say p_1' and p_2', and let the final temperatures be θ_{10}' and θ_{20}'. Then two more equations, similar to equations (**4**) and (**5**), may be written, giving altogether four equations with three unknown quantities. If these quantities, determined from three of the equations, also satisfy the fourth, then all is well and an additional check has been obtained on both the theory and the measurements. In case of an unimportant discrepancy, an adjustment can be made of all or some of the quantities involved, to satisfy the four equations with a reasonable accuracy.

To determine k_1, equation (**6**) is applied to the beginning of the experimentally obtained heating curves of both the winding and the core. Namely, at $t = 0$, $\delta_1 = \theta_{10}$ and $\delta_2 = \theta_{20}$; $(d\,\delta_1/d\,t)_0$ is the slope of the curve (taken with the minus sign) of the lower portion of the heating curve where it is practically a straight line. Substituting these values in equation (**6**), we get:

$$k_1 = (\theta_{10}\, s_1 - \theta_{20}\, s_{12}) / (-\,d\,\delta_1/d\,t)_0 \qquad \textbf{(29)}$$

A similar expression for k_2 may be written from equation (**7**).

Knowing the foregoing five constants of the machine, the auxiliary quantities $m, n, q_1, q_2, r, \sigma$, and τ may be readily computed from the expressions given above. After this, the parameters A_1, B_1, A_2, B_2 may be evaluated for any desired values of ultimate temperature rise, θ_{10} and θ_{20}, and equations (**10**) and (**19**) used to predict the shapes of the heating curves of both the core and the winding for any desired interval of time.

The values of θ_{10} and θ_{20} depend upon the losses in the machine. Knowing the losses p_1 and p_2, and the coefficients s_1, s_2, s_{12}, the values of θ_{10} and θ_{20} may be determined by solving equations (**4**) and (**5**) as simultaneous equations. The result is

$$\theta_{10} = \frac{p_1\, s_2 + p_2\, s_{12}}{s_1\, s_2 - s_{12}^2} \qquad \textbf{(30)}$$

$$\theta_{20} = \frac{p_2\, s_1 + p_1\, s_{12}}{s_1\, s_2 - s_{12}^2} \qquad \textbf{(31)}$$

Thus, with the aid of the foregoing theory, knowing the ultimate temperature rise at two different loads, and the initial slope of the heating curves at one of these loads, it is possible to predict the complete shape of the heating curves under any load conditions for which the losses are known.

Instead of determining, experimentally, the ultimate temperature rise at two different loads, it is also possible to use only one set of heating curves (one for the core and one for the winding), even without reaching the ultimate temperatures. In this case the unknown thermal constants of the machine should be determined by the method of least squares, to satisfy equations (**10**) and (**19**)[7]. The computations will be considerably more involved, but a heat run is saved, and the only heat run to be performed need not be continued until the stationary conditions have been reached. With very large machines, these considerations may outweigh the tediousness of extra computations.

NOTATION

- A a constant, in deg. cent.
- B a constant, in deg. cent.
- k thermal capacity of a body, in kw-hrs. per deg. cent.
- m defined by equation (**13**), in (hours)$^{-1}$
- n defined by equation (**14**), in (hours)$^{-1}$
- p heat input, in kw.
- q defined by equation (**15**), in (hours)$^{-1}$
- r defined by equation (**16**), in (hours)$^{-1}$
- s thermal dissipation coefficient, in kw. per degree centigrade of temperature difference; this coefficient includes the heat loss to the ambient medium and that to the other part of the composite body.
- t time, in hours
- x auxiliary notation for σ^{-1} and τ^{-1}, equations (**11**) and (**12**)
- δ deficiency in temperature, that is, the difference $\theta_0 - \theta$.
- θ temperature rise, in degrees centigrade, above the ambient medium.
- θ_0 ultimate temperature rise.
- σ, τ time constants of a combination of two bodies, in hours.

NOTE 1. Where the subscripts 1 and 2 are used in the text, 1 refers to a copper winding and 2 refers to the iron core separated from it by a layer of insulation. The subscript 12 refers to the heat conductance of this insulation.

NOTE 2. The fundamental units assumed in the notation are the kilowatt, the kw-hr., the hour, and the deg. cent. However, the formulas hold true with any units, provided that these are consistent among themselves; for example, the watt, the joule, the second, and a degree of any desired thermometer scale.

Alternating Current Analysis

BY RALPH D. MERSHON
Fellow, A. I. E. E.

FOR a good many years past, I have made use of an analytic method, of solving alternating-current problems, requiring simple algebra only. Inquiry appears to indicate that it has not heretofore appeared in print, or been used by others. For most purposes, it appeals to me more than any of the usual methods. With the thought that it may make a similar appeal to others, the bases of it and a few simple applications by way of illustration are given in what follows.

Suppose we have a resistance r and a reactance x, in series; and suppose we impress upon the circuit the voltage e. The alternating voltage triangle gives us the relation:

$$e^2 = (i\,r)^2 + (i\,x)^2 \tag{1}$$

Now though equation (1) applies directly only to a circuit in which the resistance and reactance are in series, it will also apply to a circuit made up of resistances and reactances in parallel, or to a mixed circuit of resistances and reactances in any and all possible series and parallel arrangements; *provided*, the value of r in the equation is such that its effect will be the equivalent of the combined effect of the separate resistances in the mixed circuit; and *provided*, the value of x is such that its effect will be the equivalent of the combined effect of the separate reactances in the mixed circuit. That is, for any mixed circuit there are values of resistance and of reactance, respectively, which when employed in a simple series circuit will give the same results, as to current and phase, as are given by the combined action of the separate resistances and reactances of the mixed circuit.

If we multiply equation (1) by i^2 we get:

$$(e\,i)^2 = (i^2\,r)^2 + (i^2\,x)^2 \tag{2}$$

Broadly interpreted, equation (1) says that the square of the component of impressed e. m. f. in step with the current, added to the square of the component of impressed e. m. f. in quadrature to the current, gives a value equal to the square of the impressed e. m. f. While equation (2) says that the square of the "active power" added to the square of the "reactive power" gives a value equal to the square of the "apparent power." The method is based upon equation (2).

The only difference of phase there can be in the case of active power is that of 180 deg. That is, if we calculate the active power of any subcircuit[1] of a mixed circuit, it will either be in step with the active power of any other given subcircuit, or it will be directly opposed to it; *i.e.*, it will be either positive or negative with respect to it. Therefore, the active power components of the several subcircuits of a mixed circuit may be algebraically added. The same thing is true for the reactive power. The only case in which active power can be negative is that in which a component of generated e. m. f.—other than the impressed e. m. f., and opposed to the current—is included in the circuit or in one of its subcircuits. In the case of reactive power, however, the sign may be negative without an additional generated e. m. f., since we may have a negative—*i. e.*, condensive—reactance in circuit.

It follows, therefore, that we can lay down this general rule of procedure, applying to any circuit or any part thereof:

Calculate the active power of each subcircuit. Find the algebraic sum of the values of active power of the several subcircuits. This sum is the total net active power of the whole mixed circuit. Following a similar procedure relative to the reactive power, find the total net reactive power of the whole mixed circuit. The sum of the squares of these two quantities is equal to the square of the apparent power delivered to the circuit as a whole.

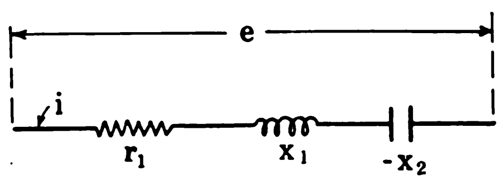

FIG. 1

By making use of this rule, alternating-current circuits may be solved by the use of simple algebra. Furthermore, only resistances and reactances, and their combinations, need be dealt with. There will be no necessity for employing their reciprocals and combinations thereof.

Applying the method to the circuit of Fig. 1, we have:

$$(e\,i)^2 = (i^2\,r_1)^2 + (i^2\,x_1 - i^2\,x_2)^2 \tag{3}$$

From this we obtain:

$$e = i\,\sqrt{r_1^2 + (x_1 - x_2)^2} \tag{4}$$

$$i = \frac{e}{\sqrt{r_1^2 + (x_1 - x_2)^2}} \tag{5}$$

The power factor is:

$$\cos\varphi = \frac{i^2\,r_1}{e\,i} = \frac{r_1}{\sqrt{r_1^2 + (x_1 - x_2)^2}} \tag{6}$$

1. The term subcircuit is used to indicate any one of the simplest branches of which the mixed circuit is made up. That is, a branch in which all the resistances and reactances are in series. When a circuit consists of one single series branch, then there is no subcircuit; or, the circuit is, itself, the subcircuit.

For Fig. 2 we have:

$$(e\,i)^2 = (i_1^2\, r_1 + i_2^2\, r_2)^2 + (i_1^2\, x_1^2 - i_1^2\, x_2 + i_2^2\, x_3 - i_2^2\, x_4)^2 \qquad (7)$$

But from (5) we know that:

$$i_1^2 = \frac{e^2}{r_1^2 + (x_1 - x_2)^2} \qquad i_2^2 = \frac{e^2}{r_2^2 + (x_3 - x_4)^2}$$

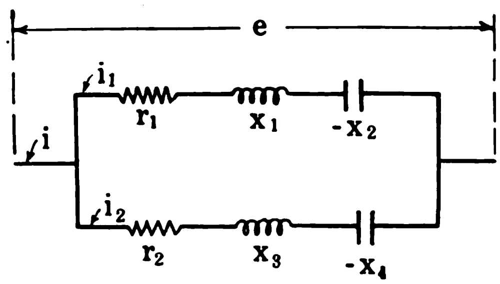

FIG. 2

Substituting these values for current in (7) and reducing

$$i_3^2 = \frac{e_3^2}{r_3^2 + x_3^2} \qquad i_4^2 = \frac{e_3^2}{r_4^2 + x_4^2}$$

We know from (8) that:

$$e_1^2 = \frac{i^2}{\left(\frac{r_1}{r_1^2 + x_1^2} + \frac{r_2}{r_2^2 + x_2^2}\right)^2 + \left(\frac{x_1}{r_1^2 + x_1^2} + \frac{x_2}{r_2^2 + x_2^2}\right)^2} = \frac{i^2}{a^2} \qquad (13)$$

$$e_3^2 = \frac{i^2}{\left(\frac{r_3}{r_3^2 + x_3^2} + \frac{r_4}{r_4^2 + x_4^2}\right)^2 + \left(\frac{x_3}{r_3^2 + x_3^2} + \frac{x_4}{r_4^2 + x_4^2}\right)^2} = \frac{i^2}{b^2} \qquad (14)$$

In which a and b are used to indicate the quantities in the denominators in order to avoid the repeated

$$i = e\sqrt{\left(\frac{r_1}{r_1^2 + (x_1 - x_2)^2} + \frac{r_2}{r_2^2 + (x_3 - x_4)^2}\right)^2 + \left(\frac{x_1 - x_2}{r_1^2 + (x_1 - x_2)^2} + \frac{x_3 - x_4}{r_2^2 + (x_3 - x_4)^2}\right)^2} \qquad (8)$$

The power factors of the whole circuit, the upper subcircuit and the lower subcircuit are, respectively:

$$\cos\varphi = \frac{i_1^2\, r_1 + i_2^2\, r_2}{e\, i} = \frac{\frac{r_1}{r_1^2 + (x_1 - x_2)^2} + \frac{r_2}{r_2^2 + (x_3 - x_4)^2}}{\sqrt{\left(\frac{r_1}{r_1^2 + (x_1 - x_2)^2} + \frac{r_2}{r_2^2 + (x_3 - x_4)^2}\right)^2 + \left(\frac{x_1 - x_2}{r_1^2 + (x_1 - x_2)^2} + \frac{x_3 - x_4}{r_2^2 + (x_3 - x_4)^2}\right)^2}} \qquad (9)$$

$$\cos\varphi_1 = \frac{i_1^2\, r_1}{e\, i_1} = \frac{r_1}{\sqrt{r_1^2 + (x_1 - x_2)^2}} \qquad (10)$$

$$\cos\varphi_2 = \frac{i_2^2\, r_2}{e\, i_2} = \frac{r_2}{\sqrt{r_2^2 + (x_3 - x_4)^2}} \qquad (11)$$

From these values of $\cos\varphi$ we may obtain the phase angles between the currents and between them and the e. m. fs.

In the preceding, a positive and a negative reactance is assumed in each subcircuit, in order to illustrate the method more clearly. A single reactance might have been employed as representing the algebraic sum of the reactances in each subcircuit, just as the single resistance represents the algebraic sum of the resistances. In Fig. 3 such an expedient has been adopted, in order to simplify operations. In the following equations, therefore, while the reactances are all shown as positive, they may be either positive or negative.

For Fig. 3 we have:

$$(e\,i)^2 = (i_1^2\, r_1 + i_2^2\, r_2 + i_3^2\, r_3 + i_4^2\, r_4)^2 + (i_1^2\, x_1 + i_2^2\, x_2 + i_3^2\, x_3 + i_4^2\, x_4)^2 \qquad (12)$$

But we know from (5) that

$$i_1^2 = \frac{e_1^2}{r_1^2 + x_1^2} \qquad i_2^2 = \frac{e_1^2}{r_2^2 + x_2^2}$$

writing of them. Substituting these values of e_1^2 and e_3^2 in the equations for currents we have:

$$i_1^2 = \frac{i^2}{(r_1^2 + x_1^2)\, a^2} \qquad (15)$$

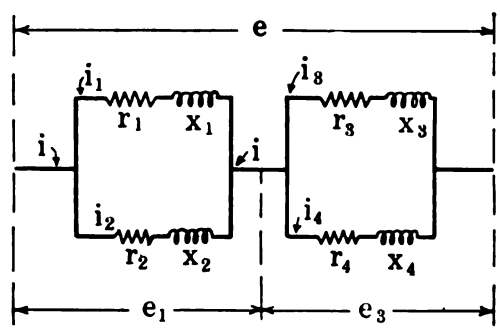

FIG. 3

$$i_2^2 = \frac{i^2}{(r_2^2 + x_2^2)\, b^2} \qquad (16)$$

$$i_3^2 = \frac{i^2}{(r_3^2 + x_3^2)\, b^2} \qquad (17)$$

$$i_4^2 = \frac{i^2}{(r_4^2 + x_4^2)\, b^2} \qquad (18)$$

Putting these values of i_1^2, i_2^2, i_3^2 and i_4^2 in (**12**) and reducing we get:

$$i = \frac{e}{\sqrt{\left(\frac{r_1}{(r_1^2+x_1^2)a^2}+\frac{r_2}{(r_2^2+x_2^2)a^2}+\frac{r_3}{(r_3^2+x_3^2)b^2}+\frac{r_4}{(r_4^2+x_4^2)b^2}\right)^2+\left(\frac{x_1}{(r_1^2+x_1^2)a^2}+\frac{x_2}{(r_2^2+x_2^2)a^2}+\frac{x_3}{(r_3^2+x_3^2)b^2}+\frac{x_4}{(r_4^2+x_4^2)b^2}\right)^2}}$$

$$= \frac{e}{c} \qquad (19)$$

Where c is used to avoid repeating the quantity under the radical.

Substituting this value of i in equations (**13**), (**14**), (**15**), (**16**), (**17**) and (**18**), we get:

$$e_1 = \frac{e}{a\,c} \qquad (20)$$

$$e_3 = \frac{e}{b\,c} \qquad (21)$$

$$i_1 = \frac{e}{a\,c\,\sqrt{r_1^2 + x_1^2}} \qquad (22)$$

$$i_2 = \frac{e}{a\,c\,\sqrt{r_2^2 + x_2^2}} \qquad (23)$$

$$i_3 = \frac{e}{b\,c\,\sqrt{r_3^2 + x_3^2}} \qquad (24)$$

$$i_4 = \frac{e}{b\,c\,\sqrt{r_4^2 + x_4^2}} \qquad (25)$$

The power factors of the circuit as a whole and of the several sub-circuits are found after the manner previously employed. From them can be obtained all the phase angles.

In Fig. 3 let:

$r_1 = 0$	$r_2 = \infty$	$r_3 = 0$	$r_4 = r_4$
$x_1 = x_1$	$x_2 = \infty$	$x_3 = -x_3$	$x_4 = x_4$

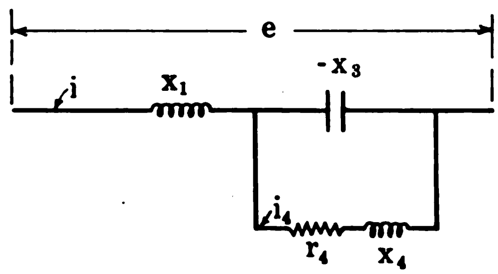

Fig. 4

Then Fig. 3 resolves itself into Fig. 4. And if these values be substituted in equation (**25**) we have:

$$i_4 = \frac{e}{\sqrt{r_4^2+x_4^2+\frac{((x_1-x_3)^2+r_4^2)\,x_1^2}{x_3^2}-\frac{2\,(r_4^2+x_4^2)\,x_1}{x_3}+2\,x_4\,x_1}} \qquad (26)$$

Now let x_3 be numerically equal to x_1. Then equation (**26**) becomes:

$$i_4 = \frac{e}{x_1} \qquad (27)$$

That is, i_4 is constant for all values of r_4 and x_4.

This is Boucherot's beautiful scheme for obtaining constant current from a constant voltage source, and vice versa. Unfortunately, it cannot be fully realized in practise, because we cannot have r_1 and r_3 equal to zero. That is, we cannot obtain a condenser and an inductance with no losses in them. However, the condition of constant current may be closely approximated over a limited range, the closeness of approximation and the extent of the range depending upon how low the losses in the condenser and the inductance, respectively, can be kept.

THE LUMINOUS FOUNTAIN OF PARIS

During a recent exposition in Paris some spectacular performances on the River Seine were carried on by means of a specially built and installed array of luminous fountains. Along each side of the Alexander Bridge a steel pipe 1 ft. in diameter with 9000 small holes was suspended, and a 200-h. p. motor pump delivered water under pressure to these two pipes. The closely spaced water jets formed a parabolic curtain on each side of the bridge. A large number of 2000-cp. floodlights, arranged under the bridge and out of sight, illuminated these two curtains brilliantly. As it was necessary to point all of these floodlights downward, their reflectors had to be watercooled to prevent overheating.

Near the bridge several floating luminous fountains were installed. These were specially designed for the purpose and entirely self-maintained. They consisted of round steel caissons of 23-ft. diameter, containing two motor pumps for the high-pressure water and three rings of floodlamps, throwing beams of light through water-tight glass panels upward upon the rising jets of water. There was room within the caisson for an attendant who changed color filters on the floodlamps. Harmonious color effects were assured by means of telephone interconnections between the fountains and to the shore.

Study of Time Lag of the Needle Gap

BY K. B. McEACHRON*
Member, A. I. E. E.

and

E. J. WADE*
Associate, A. I. E. E.

Synopsis.—*The study of high-voltage, steep-wave-front transients is difficult from the experimental standpoint because of the very short times involved. Due to the improvement which the cathode-ray oscillograph has enjoyed in recent years, a device is now available, by the use of which transients occuring in times as short as one-millionth of a second or less may be photographed. In the paper, the authors used an oscillograph developed by Dufour in France, with which a brief study was made of the time lag of needle gaps and of a needle to a plane.*

A description of the oscillograph is given including a discussion of the method of operation. The photographic film is placed inside the tube so that the electrons impinge directly on the film. The wave is drawn out along a time axis by the combined action of a sweeping motion and a perpendicular oscillating motion imparted to the electron stream by the action of proper electromagnetic fields.

Tests were made with a wave which was nearly perpendicular, reaching its maximum in about one microsecond. Such a wave was obtained by the discharge of a condenser through a suitable circuit. An oscillogram which shows the wave front used is given, and attention is directed to the 20,800 kilocycle oscillation which appears superimposed on the wave front.

The results of tests in which this wave front was applied to gaps are given and it is shown that with any given gap setting and sparking voltage that the time lags vary through wide limits. It is also shown that, for the same voltage, increased gap settings mean increased lag. The per cent overvoltage, required to keep the lag to two microseconds or less, decreases as the gap spacing increases.

* * * * *

THE STUDY OF TRANSIENTS

ONE of the most difficult and perhaps also one of the most fascinating problems which the electrical engineer of today is called upon to study is that of the transient phenomena occurring in electrical circuits. Failure of apparatus, caused by the puncture or flash-over of insulation due to overvoltages, the duration of which may be of the order of a few micro-seconds, has made desirable the use of lightning arresters which limit the voltage to safe values. Since in practise many of the steep front traveling waves are the result of the sudden releasing of a bound electrostatic charge, lightning arrester laboratories have used the discharge of a suitable condenser to simulate the actual line condition. For this purpose, and for the study of the action of insulation and gaps, impulse generators have been built which may be charged to values as high as 2,000,000 volts.

The limitations and some, at least, of the possible sources of error involved in the use of the impulse generator have been recognized by lightning-arrester engineers for some time. Three years ago the authors began to search for means of recording, on a photographic film, transient phenomena the frequency of which might be a million cycles per second or more. As a result of this search of the literature, the device described in this paper was found.

OSCILLOGRAPHS

A satisfactory oscillograph for the delineation of the volt- or current-time characteristic of a short-time transient must satisfy the following conditions:

1. The device must have no appreciable inertia and must be capable of operating at a frequency of at least one million cycles per second.
2. The device must use little energy in its operation, so that its use will not appreciably disturb the original circuit.
3. The device should be capable of registering both voltage and current simultaneously.
4. The apparatus must be so arranged that a single impulse will be sufficient for a satisfactory photographic impression.
5. The oscillograph should be as simple as possbile and have sufficient accuracy so that the results may be used with confidence.

The first point can be satisfied only by some device using the flow of electrons. When thinking of the available devices, one naturally turns to the Braun tube which has been used for many years as an oscillographic device. As originally developed, the Braun tube consisted of a cathode and an anode in an exhausted tube, together with a fluorescent screen. Unidirectional voltage from a static machine causes a flow of electrons from the cathode to the anode, some of which pass through a small hole in the anode and are deflected by magnetic or electrostatic fields produced by the phenomena being studied, The rays then pass on to the fluorescent screen where a graph is traced the coordinates of which are determined by the deflecting fields. If the phenomenon repeats itself, the graph appears as a stationary pattern, and may be recorded photographically using an exposure of several seconds.

The Braun tube has negligible inertia, and very little energy is required to cause the deflection of the cathode beam. Its speed is the speed of the electron which may be varied between quite wide limits especially if using a heated cathode as in the Western Electric tube. The upper limit of velocity is perhaps one-half that of light.

The fourth condition mentioned, that of recording a single impulse, may be satisfied by placing the photographic film inside the tube in such a way that the electron stream impinges directly on the film. This has been done by several investigators with marked success.

The literature of the Braun tube is quite extensive, and but a few of the available references are given at the end of this paper.

Abridgment of paper presented at Regional Meeting of Dist. No. 1, Swampscott, Mass., May 7-9, 1925, and at the Annual Convention of the A. I. E. E., Saratoga Springs, N. Y., June 22-26, 1925. Complete copies to members on request.

To a Frenchman, Alexander Dufour, belongs the credit for adapting the Braun tube to the study of transient phenomena. This development is characterized by means whereby a photographic film is placed inside the vacuum chamber and also an arrangement for drawing out the transient along a time axis so that the highest frequencies may be studied.

The Dufour Oscillograph

A description of this oscillograph which was used in the needle-gap lag tests is given in the following paragraphs.

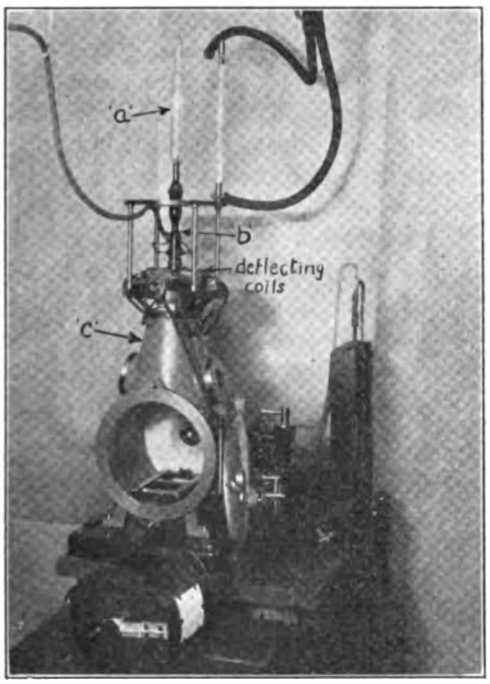

Fig. 1—Dufour Oscillograph

Referring to Fig. 1, the oscillograph consists essentially of glass tubes *a* and *b*, fitted by means of a ground joint into the bronze chamber *c*. The upper glass tube *a* carries the cathode and anode. The tube *b* has one pair of deflecting plates for electrostatic deflection of the electron stream. For magnetic deflection two sets of coils, 1—1 and 2—2 (Fig. 2), perpendicular to each other, are placed external to the tube and located slightly below the deflecting plates. The coils are arranged so that they may be rotated about the axis of the tube, thus allowing adjustment of the angle between the axes of the deflecting fields.

To operate the oscillograph expeditiously, easy means must be provided for changing films quickly. It is also necessary that a fluorescent screen be arranged so that it can be removed when making an exposure. How this is done in the Dufour oscillograph may be seen by referring again to Fig. 1. The drum, which in the illustration appears in the foreground, is provided with a film magazine which allows six films to be taken in succession. When viewing the phenomena, a fluorescent screen is turned up into position covering the opening into the interior of the drum so that the films are not exposed when using the screen. After placing the films in the drum, it is placed inside the bronze chamber and locked in position. The opening is closed by a door having a very carefully constructed joint so that the tube may be made air tight. Three cocks, turning in ground joints placed in the door, serve to operate the mechanism for changing films and moving the fluorescent screen. Two glass windows, one on either side of the bronze chamber, permit of easy view of the fluorescent screen.

Operation of the Oscillograph

For slow speed work a moving drum to take the place of the magazine drum may be used. This drum is driven by means of an external motor and magnetic clutch. A simple calculation shows that such a drum cannot be rotated at a sufficiently high velocity to draw out the oscillations so that they may be studied. To draw out a one million-cycle wave in a manner similar to that used with the ordinary Duddell oscillograph, so that two millimeters are allowed per cycle, would require a film velocity of 2000 meters (6650 feet) per second.

This problem has been solved by Dufour in a very satisfactory manner. Rather than move the film,

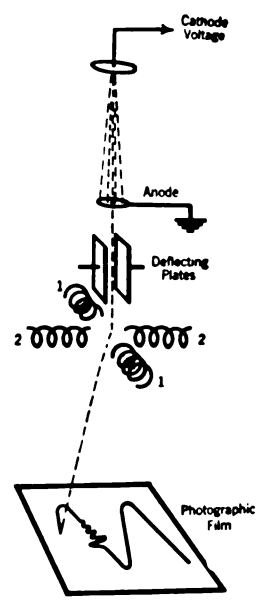

Fig. 2—Diagramatic Representation of Oscillograph Operation

the electron stream is subjected to the action of auxiliary fields which draw out the wave without the limitations of a mechanical system, as shown in Fig. 2. The method by which this is accomplished may be understood by reference to Fig. 3. In I is shown the effect of passing a transient current through coils 1—1. With the proper circuit arrangements the beam is held off the film at the top until ready for the photograph to be taken, when a transient takes place which sweeps the beam across the film holding it off the film at the

bottom. This transient current will be referred to as the sweeping current.

A source of high frequency (a vacuum tube oscillator) is connected to coils 2—2, which are mechanically spaced 90 deg. from coils 1—1. With coils 2—2 energized, the oscillator traces a straight line on the film, the amplitude usually being adjusted to utilize the entire width of the film. When coils 1—1 and 2—2 are operated together the oscillator waves are drawn out as seen in III. If the oscillator frequency is 50,000 cycles and the effective width of the film 100 mm. (3.9 in.), then the average distance corresponding to one microsecond would be 10 mm. (0.39 in.). This means that if a million-cycle wave was impressed on the deflecting plates so that the beam was deflected thereby in the same direction as by the sweeping current, it

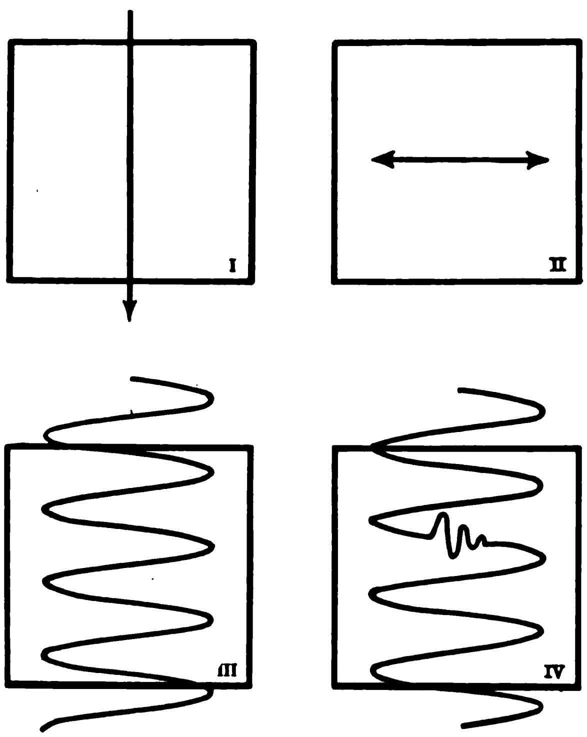

FIG. 3—METHOD OF REGISTERING TRANSIENT PHENOMENA
I. Sweeping III. Sweeping and Oscillator
II. Oscillator IV. Transient superimposed on III

would be drawn out sufficiently so that the wave form could be determined and IV shows the effect of the combination of the three fields. The oscillator wave is the zero line for the transient being studied and it is a time axis whose unit of measure is varying according to the sine law. The speed of sweeping is always a compromise between drawing out the oscillator wave and the difficulty of getting the unknown phenomena timed so as to appear on the film. With much slower speed phenomena, the sweeping field may be placed 90 deg. from that of the unknown transient, so that the time axis becomes a straight line across the film. This axis may be conveniently calibrated by superimposing a known high frequency using the oscillator coils.

Thus it is possible to get volt-time or ampere-time curves with a time axis which can be calibrated with considerable accuracy. Volt-ampere characteristics may be taken by applying to the cathode stream, fields proportional to the voltage and current and spaced 90 deg. apart.

THE CATHODE STREAM

The best registration on the film is obtained when conditions are such that a fine pencil of rays strikes the film only when required. Not only is it desirable to hold the rays off from the film before and after the transient, but the operation of the tube is much improved if the cathode voltage is applied for just sufficient time to allow the proper registration of the unknown transient.

The necessary cathode potential may be obtained by the use of either a high-voltage direct current, or a few degrees of the crest of an alternating potential The latter method may only be used with phenomena which are fast compared to the change of potential. during its registration. This method was mentioned by Dufour as being particularly adapted to the study of very short time transients, and as this method is very convenient it was adopted for use in this study of gap characteristics.

TIMING THE TRANSIENT

The spot made on the photographic film by the electron stream may travel as fast as 80 km. (50 mi.) a second across the film; and since it is not feasible to get a developed registration length of more than 10 or 12 meters (32.8 to 39.2 ft.) on the film, the transient must be initiated during the very short interval of time in which the spot is sweeping across the film.

A rotary switching device has been built which makes the necessary contacts so that voltage is applied to the cathode, the sweeping started and the unknown phenomenon so timed as to appear on the film. The oscillator is connected before voltage is applied to the cathode, and remains connected until after the exposure has been made. The arrangements are such that only the pushing of a button is required to set in operation a mechanism which makes all connections automatically.

TIME LAG OF NEEDLE GAPS

It is known that a needle gap shows considerable lag when subjected to steep wave front impulses. The brief study which is presented herewith measures definitely the lags encountered under the given conditions. The results are not complete, but do give for the first time, as far as the authors are aware, a direct measurement of lags as short as a few micro-seconds. The methods used here are being applied to the study of the problems encountered in lightning arrester practise and will yield results of great importance.

The time lag of a gap may be taken as the time elapsing until breakdown occurs during which the applied potential exceeds the low frequency spark potential. For a voltage only slightly in excess of the

low frequency spark potential the time lag may be long, while with steep wave fronts of high voltage it will be extremely short. The lag with any given gap is determined not only by the voltage at the time of spark-over, but also by the shape of the wave front used.

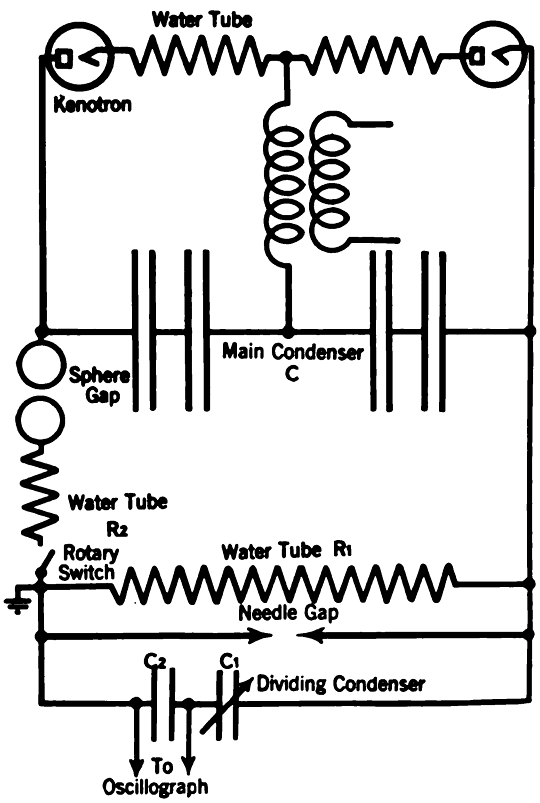

FIG. 4—CONNECTION DIAGRAM

The purpose of these tests is to find the effect of successive increments of overvoltage on the time lag. To avoid the complication of a sloping wave front, it was thought best to use as nearly rectangular a wave as could be obtained. It is impossible to produce a perfect rectangular wave but if the time required for the voltage to reach a constant value is small in comparison with the time taken by the gap under test to spark over, the error will be negligible.

TEST ARRANGEMENTS

An impulse generator, which was built for use in connection with the testing of lightning arresters, was used as a source of voltage. This generator consists of two hundred glass plates with tinfoil coatings divided into four groups connected in series, each group consisting of 50 plates in parallel, giving a capacity of 0.13 microfarads. A connection diagram is given in Fig. 4 and shows the limiting sphere-gap which determines the voltage at which discharge will take place. The water tube resistance, R_1, allows the sphere-gap to charge up properly, while R_2 is used to control the wave front as will be shown later. The dividing condensers, C_1 and C_2, were used for reducing the voltage to the proper value for the deflecting plates on the oscillograph.

The oil-immersed dividing condensers are shown in Fig. 5, together with the needle gap being tested. The capacity of C_1 at the setting used on the tests was about 20 micro-microfarads. Variable stray capacities to ground and inductive effects between the condenser and the oscillograph were eliminated by using a ground shield around the dividing condenser.

Voltage calibrations were obtained from capacity measurements, and more directly by taking oscillograms when holding a known 60-cycle voltage on the dividing condensers.

WAVE FORM

Fundamentally, the circuit shown in Fig. 4 represents the discharge of one capacity into another with small series inductance and considerable series resistance. The circuit is of course complicated by the use of series gaps, wires leading to oscillograph, etc. With such a circuit, the series resistance R_2 will increase the time required to charge the capacity of the dividing condenser and connections.

The effect of changing R_2 may be seen by referring to Fig. 6, which shows the wave fronts with three different values of resistance. The method of registration used is the same as that described in connection with Fig. 3 and consists in applying an upward sweeping motion, combined with the horizontal motion of the oscillator. Superimposed is the discharge of the condenser which is initiated by the action of the rotating switch.

On the oscillograms given in Fig. 6 will be found two sets of oscillations, the first being damped out rather quickly. This oscillation, which has a frequency of approximately 20,000 kilocycles, occurs when the rotating switch sparks and is followed by another when the limiting gap sparks. There is a certain variable time interval between the sparking of these two gaps.

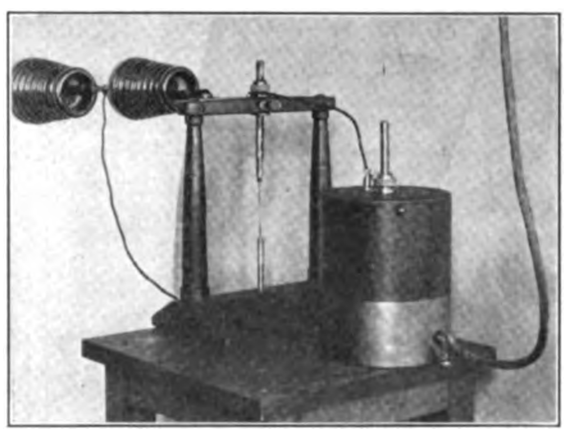

FIG. 5—DIVIDING CONDENSERS AND TEST NEEDLE-GAP

In making these tests the aim was to obtain a steep wave front but at the same time to prevent the voltage from over shooting. Film 300 (Fig. 6) shows the main

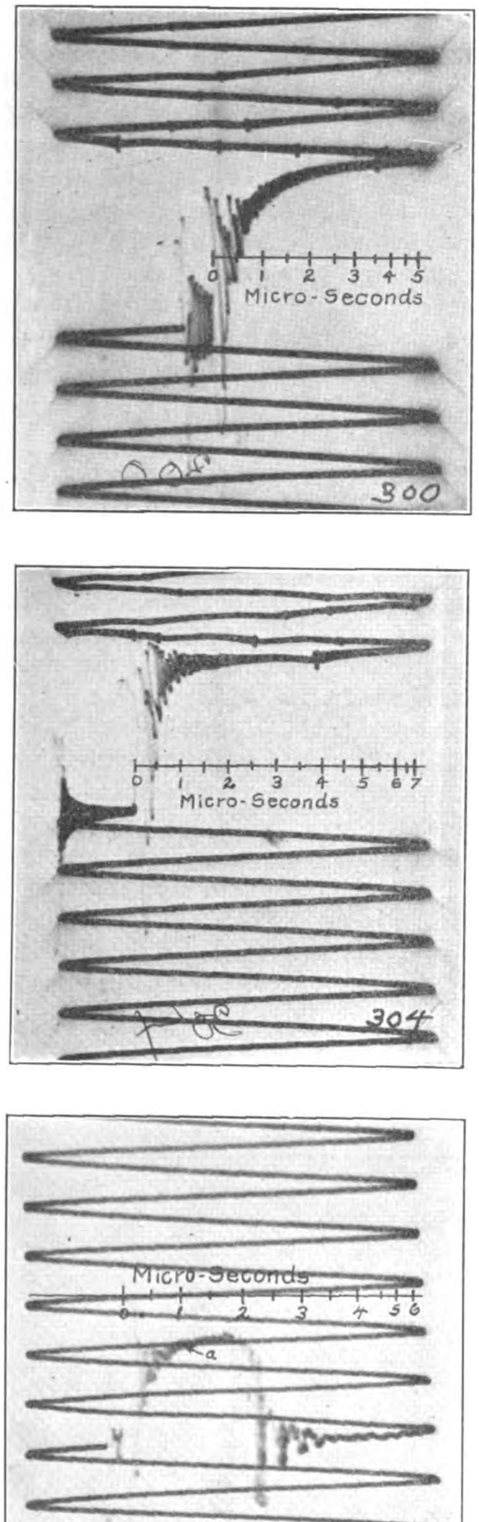

FIG. 6—OSCILLOGRAMS SHOWING THE WAVE FRONT USED ON NEEDLE GAP TESTS

transient rising to its maximum value in about 25. micro-seconds. Superimposed on this wave front are oscillations which are made up of a combination of several frequencies. Film 300, which was taken with 1100 ohms in series, shows that none of the oscillations has a voltage exceeding the maximum value of the main transient.

The series resistance was reduced to 570 ohms and film 304 taken. This film shows that the main transient rises to its maximum in about 0.4 micro-second. This resistance is too small however, as some of the crest values of the superimposed oscillation exceed the final voltage. A value of 700 ohms was chosen as being the best compromise between the steepness of wave front and the condition of overshooting. Film 593 was taken, using this series resistance, and it was found that a time of one micro-second was required for the voltage of the main transient to reach its full value (marked *a* on the film). This film is interesting as it shows the sparking of a needle-gap 0.8 micro-second after full voltage had been applied.

RESULTS OF TESTS

The time lags under most test conditions used exceeded two micro-seconds, which made the use of the oscillator undesirable except for timing purposes; therefore, nearly all results were taken with the sweeping only, as this allowed several exposures on one film. With six films and five tests per film, it was possible to get 30 tests before releasing the vacuum and changing the magazine drum. The use of the sweeping also gives a uniform time scale for the measurement of the lag.

The results of nine representative tests are given in Figs. 7A and B. As this type of oscillogram is probably new to most of the readers of this paper a brief explanation is given. The different tests are numbered in the order in which they were made. In the first test, for instance, which is at the bottom of the film, (No. 543), the cathode spot comes on the film from the left, being swept across the film at a uniform rate corresponding to 4.5 micro-seconds per mm. About 190 micro-seconds later the voltage is applied by the operation of the rotating switch. The cathode beam is deflected upward and traces a horizontal line, parallel with the zero axis, until after 140 micro-seconds the needle-gap under test breaks down and the cathode spot falls to zero and so continues, passing off the film at the right. Although the wave front in this film appears perpendicular, it is really as shown in Fig. 6, film 593.

Four needle-gap breakdowns are given in film 558, Fig. 7B, the voltage being 5 kv. with a needle gap spacing of 60 mm. This film shows a 50-kilocycle timing wave which fixes the time calibration. Fig. 7A film 543 shows the result of tests on a 15-mm. needle-gap with 22 kv. applied. These oscillograms show very nicely the steepness of the wave front compared with the time lags; and also how well the cathode ray oscillograph is adapted to the study of short time phenomena.

Results were obtained from a series of oscillograms for three different voltages and with different needle-gap spacings. Tests were also made with a needle to a plane and between needles having different degrees of sharpness. Some of the results are given in Table I.

An analysis of the results brings out certain relations which are briefly discussed.

For each voltage used, the gap setting, corresponding to infinite lag, will be slightly above the 60-cycle setting for that voltage. The per cent overvoltage above the 60-cycle spark potential necessary to obtain lags of one micro-second or less was found to decrease with increased spacing.

With spacings of 10, 40 and 65 millimeters the per cent overvoltages are 75, 40 and 29 respectively. It is, of course, to be expected that the greater the per cent of overvoltage the shorter the time lag. The results show that this is true, in general, although wide variations in time lag occur with every setting and at all voltages.

An examination of the results discloses the existence of time-lag zones, which indicates that breakdown is more likely to occur within these zones than outside. The existence of these zones is doubtful in some cases, while in others it seems well defined, as for instance at 75 kv. with a 95-mm. spacing (Table I).

In general, the tests show that dull needles give shorter time lags than sharp needles, although more tests should be made to be certain of the relationship.

Comparing the point-plane tests (Point negative), with the needle points having the same spacing the data show that the lags are of the same order of magnitude although the maximum lag with the point-plane is considerably greater than the corresponding value for the points. Tests made with the point positive show that the lag is less than two micro-seconds while with

72 mm. Needle Gap	Relative humidity 26 per cent Bar. 28.8 in. Temp. 19 deg. C.	2.4	38- 38- 43- 48- 26 43- 29- 38- 21- 48 29- 45- 29- 29- 29 29- 2- 17- 55- 60 31- 53- 41- 31- 31	Max. 60 Min. 2 Av. 35	4	48	28	20

the point negative with the same spacing and voltage an average lag of 62 micro-seconds was obtained. When the point was negative with a spacing of 13 mm. sparking occurred with approximately 50 per cent of the voltage applications. With the point positive a similar condition was obtained with a spacing of 19 mm. These results give some conception of the effect of polarity on the lag of a point-plane gap.

Conclusions

An oscillograph is now available, as represented by that made by Dufour, by the use of which single transients may be photographed, without being limited by the inertia of a mechanical system. By its use, wave forms have been photographed having measurable oscillations up to 20,000 kilocycles. The authors have worked with an oscillator frequency of 250 kilocycles which allows the registration of a frequency of 100,000 kilocycles. As the frequency increases, the problem of the characteristics of the circuit used become increasingly important and great difficulty is experienced in keeping the oscillograph circuits free from disturbances emanating from the main impulse circuit. The cathode-ray oscillograph, as used here, becomes a tool of the greatest value in the study of transient phenomena.

The lag tests, with constant voltage on the needle gaps, show that the lags vary between wide limits, the average lag increasing with increased gap settings. The limits could probably be narrowed considerably by the use of careful control of air and electrode conditions. The per cent overvoltage, required to keep the lag to two micro-seconds or less, decreases as the gap spacing increases. The lag is shown to depend on the condition of the needle, the dull needle tending to have the shorter lags.

The authors are continuing the use of the oscillograph, intending to apply it to the study of transients on transmission lines due to lightning and other causes. The breakdown of insulation and the operation of lightning arresters is also being investigated. Acknowledgment is gladly given to the work of Alexander Dufour, who constructed the oscillograph used by the authors in the work described in the paper.

Discussion at Pacific Coast Convention

220-KV. TRANSMISSION TRANSIENTS AND FLASHOVERS[1]

(Wood)

Seattle, Wash., September 15, 1925.

Percy H. Thomas: This paper appears to clear away definitely the persistent suspicions that there is some source of mysterious overpotential inherent in 220 kv. or in very long lines, that does not appear on the surface—something involving an unrecognized principle and jeopardizing reliability of service.

The subject of surges and high-voltage breakdowns has long been a *bête noir* for transmission operation. When power transmission first became of importance, one of the first serious sources of shut-down other than the ever-present lightning was the frequent short circuit of transformers in high-tension service. While this proved to be due partly to moisture and inadequate insulation, it was, nevertheless, necessary that the now well-known but then almost unknown effect of the steep-wave-front surge on windings be studied out[2] and this led to radical change in the method of insulating high-tension windings. While the theory of the propagation of surges or waves in transmission lines was academically known, nobody knew what the real effect in an actual line practically was and this led to a certain feeling of uncertainty as to what might be expected with plant extensions. This led to a series of investigations in 1902 in the middle west on a number of high-tension plants, similar in object to those reported by Mr. Wood and leading to a somewhat similar conclusion.[3] In the old investigation, the voltages were lower and the apparatus cruder but the interest was much the same.

At still a later period, with the advent of larger systems and higher voltages, still another experimental study was made, this time based largely upon the oscillographs covering the action of switching and surges in the system of the Pacific Gas & Electric Company[4] and still again with the result of disproving the existence of any new or unexpected phenomena.

Mr. Wood's work goes over the research again, taking up all possible sources of excessive surges and using perfected apparatus. This makes clear the conclusion that the explanation of mysterious surges even on 220-kv. lines must be sought among the well recognized laws of electric phenomena.

Considering, now, the detail of the paper, it may be pointed out that the results of the klydonograph appear to agree with the old fundamental rules of wave motion, e. g.: (a) When a potential is abruptly applied to a transmission line, a wave equal in crest to the applied potential passes along the line until it reaches a reflecting point when it is reflected back toward the start, reaching *double potential* at the *reflecting point*, neglecting losses. (b) When a small-capacity branch line leads from such a reflecting point, the wave starts off in the branch line at the maximum potential reached at the reflecting point and is subject to reflection at the end of the branch line with another doubling of the potential. (c). Whenever a condenser is charged

through reactance (neglecting resistance) the potential will rise to double the charging potential and only gradually settle down to equilibrium after a series of oscillations.

As Mr. Wood properly says, in considering surges in a line, the effect of distance of travel is only to weaken the surge. Other things being equal the effect of a switching operation is greatest nearby.

It is particularly gratifying to find that no abnormal *sustained* high-frequency potentials exist in the line, as these might be exceedingly troublesome.

F. W. Peek, Jr.: Mr. Wood's findings, which are quite in accord with theory, show no mysterious high voltages at sustained high frequency causing arcs of indeterminate distance. The expected highly damped switching surges occur but never of sufficient voltage to cause trouble. The cause of many arc-overs is dirt. In the tests made most of the dirt trouble was a purely mechanical one due to birds and as easily understandable as the effect of a fuse wire dropped over an insulator string. This investigation shows conclusively that there need be little fear from transient voltages originating in a grounded-neutral system.

Thus, in the part of the country where the lines of the Southern California Edison Company are located the chief cause of insulator arc-over is a weakening of the insulators by dirt or other mechanical means.

Other important points brought out are that high-voltage switching may be done without fear, and that with quick-acting relays insulator arc-overs may be cleared without interruption of service. Of course, in addition to quick-acting relays, it is important to have grading shields or rings on the insulator to direct the arc away from the string while the relays are operating.

While dirt is the principal cause of arc-over in certain parts of the country, in other parts its effect may be practically negligible and lightning may be a very serious factor.

To illustrate how well Mr. Wood's conclusions are in agreement with our laboratory investigation I would draw your attention to a recent discussion of mine[5] at the Annual Convention which shows that our conclusions are very similar to Mr. Wood's.

C. L. Fortescue: Klydonograph is derived from two Greek words which mean wave and record. It is a device for making a record of surges. The klydonograph is a very simple instrument which consists merely of an electrode which is connected to the line through a potentiometer device, and measures a voltage proportionate to the tension of the line. This electrode passes over a sensitized plate or film in contact with the insulated surface of a grounded plate. Now the oscillation passing over the line makes a record on this sensitized plate which, after development, shows a figure possessed of certain peculiarities. A figure for a positive wave in any direction is different from the figure for a negative wave, so that it is possible to tell what the polarity of the wave is. One can tell whether it is an oscillating wave and, with certain arrangements, know not only the character of the wave, but also the steepness of the wave fronts and the direction in which the wave is traveling. So, with this device, it is possible to obtain very complete information about surges.

The method of determining the amplitude of the wave consists in measuring the diameter of the figure. The diameter is very closely proportional to the actual amplitude of the wave within the range in which this measurement is useful. In other words, for the higher voltages where the surges are of some concern, the calibration is very close, within 15 per cent.

The first klydonograph consisted merely of an ordinary sensitized photographic plate rotated under the electrode and the plate had dials which would register time on the record. The complete rotation occupied one day. This, of course, was not very convenient inasmuch as the plates had to be changed every day. The present klydonograph is a much more suitable instrument. It consists of the same arrangement except that it has a roll film which goes over an insulated grounded cylinder. The roll needs to be changed only once a week and provision can be made for longer or shorter periods as desired.

Now, so far as possible, we are giving klydonograph service to those who have problems requiring investigation. We have about twenty of these seven-day instruments in operation. We have two experts whose work is devoted solely to looking after the instruments and giving this service. We have investigated quite a large number of systems in the east.

Of course, in carrying out this work we aim to do our field work as much as possible during the summer months when we have lightning, etc., so that we have been able to make only a preliminary analysis of the results. The preliminary analysis shows that in no case were there any signs of high frequency and, in fact the highest frequency we obtained was something less than 30,000 cycles per second. The duration of these surges is very brief. They don't travel very far. They very quickly become damped so the bogey of sustained high frequency does not exist. We haven't found it anywhere. Our experimental work has extended particularly over such portions of the United States in which lightning is very frequent and severe.

Lightning has proved to be the most prolific source of high voltages, but even lightning has caused nothing we need fear. The highest voltage hasn't gone beyond the possibility of insulation.

We expect to carry on this service to the best of our ability, but of course, we are limited as to men and also as to number of instruments. On a large system it is pretty hard to do with less than a dozen instruments; to carry out investigations properly, one should have more.

We expect to do some theoretical work in the winter months, analyzing results of the investigations of the previous months; and we probably shall have to do some work on cable systems during the winter. Cable systems have been very free from surges and that, of course, from theory is what we expect. We wouldn't expect to have the surges in cables due to effects outside, and surges from cables connected to outside lines don't amount to anything at all. I don't think that the trouble with cables can be attributed to outside sources. The troubles with cables are inherently inside the cables themselves; surges may come about due to the trouble in the cables, possibly.

I may state that grounded-neutral systems have been very free from surges due to short circuits and other abnormal operations.

J. H. Cox: Mr. Wood's instructive paper leaves little to be said to lay the ghost of alarming abnormal conditions on the 220-kv. lines of the Southern California Edison Company. As pointed out, the tests were sufficiently extensive to be truly representative of conditions on those lines. Since Mr. Wood's paper tells the whole story so far as his system is concerned, it seems appropriate to present information gathered more recently with the klydonograph on other lines.

During the year 1925 surge investigations have been made on quite a number and variety of systems, both open-wire and cable. The causes of abnormal voltages on transmission lines may be classed under three headings, switching, short circuits and grounds, and lightning.

Switching. For the most part the experience with surges resulting from operating activity has been much the same as that on the Southern California lines. Switching surges in general are less than two times normal in terms of crest voltage to ground. Only two types of operations caused higher surges. One of these was the opening of an idle but energized line on a 15-mi. free-neutral line and caused surges as high as 4.3 times normal. The other was synchronizing with a high-voltage switch at the end of a 150-mi. free-neutral line. These surges reached a maximum of 4.6 times normal.

5. A. I. E. E. JOURNAL, October 1925, p. 1151.

Short Circuits and Grounds. Experience with short circuits and grounds on other grounded-neutral systems has agreed with that on the Southern California Edison lines. No major surges on such lines have resulted from short circuits and grounds either accidentally and intentionally produced. Short circuits and grounds on free-neutral systems have, in general, produced high-voltage oscillations reaching a maximum of 4.5 times normal. These voltages were recorded on the two ungrounded phases in the case of a single-phase ground.

Lightning. As would be expected, lightning has thus far proven to be the best generator of high-voltage surges though in the California Edison System high voltages due to this cause were absent. No differentiation is made by this source between types of systems but it varies widely with locality. In one case a voltage of 1000 kv. to ground was recorded. Many other surges caused by lightning were recorded, ranging from 400 kv. to 700 kv. Some of these were oscillating and others unidirectional. The unidirectional surges were positive in polarity. The oscillating surges were usually recorded at times when an interruption was caused by the stroke.

R. W. Sorensen: During the past twelve years I have been much interested in these line flashovers. Some of our first theories as to the cause included mechanical means, such as spider webs, dirt, soiled insulators, etc. As a basis of the spider-web hypothesis there were found many big spider webs attached to the lines and it was supposed that these webs might become wet and cause some of the flashovers. The possibility of these flashovers being caused by birds was also considered. But, at that time, there was never sufficient conviction to warrant the expense of erecting devices to keep the birds away from the towers as has been done recently.

It is my endeavor in this discussion to encourage the idea of trying to solve our difficulties by doing simple things first, although it seems to be human nature to first apply complicated methods and later simple methods to problem solutions. One of the objects of engineering education should be to teach us, as engineers, to avoid a complicated method of attacking problems.

It must be borne in mind that, although it has not been mentioned in Mr. Wood's paper, he is dealing with a line to which are connected transformers with delta connections so that on this line there is no probability of getting effects such as arcing grounds might produce on Y-Y connections if these connections are not properly supplemented with tertiary windings connected in delta.

G. R. F. Nuttall: Perhaps it would not be out of place to mention the 220-kv. tie line between the Great Western Power Company and the San Joaquin Light & Power Company.

The design and tests on the standard towers have just been completed and Mr. J. A. Koontz, of the Great Western Power Company has taken particular care to shield all points on the towers so that no corona will form near the wires. In order to reduce eccentricity in the joints, it is better to place the bracing in the cage of the towers alternately inside and outside. This inside bracing ordinarily offers quite a sharp edge which is a point where corona might form. Therefore we have bolted a small angle to the outside brace which exposes its flat side to the wire.

Mr. Wood mentioned that they used a dynamometer in stringing their cable, I wonder if we could have information as to the type used, as the spring type is unreliable at the higher tensions.

I should like to present for discussion the question of insulation, not of the line itself but at the ends of the line. Mr. Wood's paper has given us useful information on transient voltages and 220-kv. operation and I wonder what the manufacturers' views are as to the rating of their bushings for oil switches and transformers.

In the case of the Pacific Gas & Electric Company and the Southern California Edison Company I think I am right in saying that the A. I. E. E. ruling (Sept. 1922) has not been upheld. The switch bushing ought to be tested for $2\frac{1}{4}$ times the line-to-line potential which equals 495 kv. for 220 kv. operation, and the transformers (three single-phase, auto-transformers with grounded neutral) at an induced voltage of twice line-to-line potential plus 1000 which equals 481 kv. for 240 kv. at the sending end.

L. N. Robinson: In connection with Mr. Wood's paper, the most effective cure for the flashovers seems to be the bird guards. I wish Mr. Wood would give us a description of them.

D. I. Cone: I wish to comment on a by-product result of Mr. Wood's paper. The table on the seventh page and the oscillograms, tells of the investigation of the normal residual currents of the system, which were found to be without features that would aid in the explanation of transients. This record, if supplemented by data regarding the sizes of transformers, their characteristics and connections, will be of considerable value to the Joint Committee of the National Electric Light Association and the Bell Telephone System, which is studying the distribution of such residual currents in systems of this kind. A special project committee is doing work with a view to enabling us to predict these residuals and their resulting inductive effects upon neighboring lines.

Roy Wilkins: In the discussion on Mr. Wood's paper the question is brought up regarding the insulation on the oil switches and bushings and transformers used on the 220-kv. line. The transformers and switches themselves are tested for 2.73 times the normal voltages to ground; the bushings at 2.25 times line voltage. There is before the Institute's Standards Committee at the present time the proposition to change the requirements for the potential tests on grounded transformer equipment to some such value at 2.73 times line voltage.

H. Richter (communicated after adjournment): The paper states that, on the small overhead networks, the transformers are of the type having a network protector in the same case. This form of network protection has been abandoned on the two systems where it originated, because of faulty operation and lack of real protection. Experience shows that these devices are excellent transformer protectors but cannot be relied upon for network,—that is, service protection. I am rather inclined to ascribe the excellent record of 0.7 per cent transformer burn outs mentioned on the seventh page to the lightning protection offered by the common system neutral, as emphasized on the fifth page. As these protectors are so designed that they do not protect against trouble in the primary or secondary lines, their cost of about $3 per transformer-kv-a. makes a rather high insurance rate against transformer trouble. The substitution of carbon circuit breakers tripped by reverse-power relays in the underground area of Minneapolis is in line with the latest methods of network protection where real reliability of service is demanded.

In general it may be said that the loop method of primary feed is particularly applicable to bulk loads of 300 kv-a. up and fed at the higher primary voltages of 11,000 volts and above. This is because of the high cost of spare capacity in feeders and substation apparatus, high rupture capacity, loop-sectionalizing switches, and pilot-wire control. For underground areas where transformer banks, serving miscellaneous distribution loads, range from 75 to 300 kv-a. each and are spaced on the average 500 ft. apart (but may be up to a maximum of about 1000 ft. apart) there is being installed in six large cities and planned for many others, a very simple system of a-c. distribution. This is the secondary-network system with automatic network protection that was described by A. H. Kehoe[6] and by W. R. Bullard,[7] and that has been in successful operation in New York City for almost three and a half years.

6. Underground Alternating-Current Network, by A. H. Kehoe. A. I. E. E. TRANSACTIONS, 1924, p. 844.

7. A Study of Underground Distribution Systems, by W. R. Bullard. A. I. E. E. TRANSACTIONS, 1924, p. 856.

In this network system the feeders are radial, no primary protective or sectionalizing devices being necessary. The secondary mains are spliced together to form a solid mesh which requires no junction boxes and a compact triple-pole network unit, inserted in the transformer-secondary connections to the network, protects for every type of fault that might interfere with continuity of service except failure of the prime source of power. Advantage is taken of the elimination of primary switches, cut-outs and disconnecting potheads, to employ higher primary voltages such as 13,200 volts. Thus may be saved the cost of either station step-down transformers and lower voltage switches, or even of the entire substation. By limiting the feeder capacity to 150 amperes, each feeder can carry about 3000 kv-a. and be confined to either a small or a large area depending on the load density.

The system of multiple street lighting introduced in Minneapolis is undoubtedly a step ahead both from an operating and economic point of view. However, some electric service companies object to pilot wires for control and others to mercury switches. One manufacturing company has developed a system of control by a form of carrier current over the primary feeders. This dispenses with both of these features and also the reenergizing contactors. The switching units are sturdy, comparatively simple, will not be expensive and are small enough to mount in the vase of an ornamental post. They can also be used in conjunction with a primary switch, for controlling pole-mounting constant-current transformers feeding series lamps. The sender at the station is likewise simple and substantial. Further, there are practically no losses in the switching units.

The system has had a successful trial equivalent to a year's service. It is anticipated that this method of control, together with multiple street lighting, will be the standard street-lighting system of the future.

R. J. C. Wood: There was a question asked about possible slipping of aluminum on steel with changes of temperature. I have given that matter quite a little thought and have come to the conclusion that there is no longitudinal motion between the two metals. Imagine a piece of cable, steel inside and aluminum outside; somewhere it has two ends clamped together, so that the two ends cannot move with respect to each other. If you make it sufficiently hot the aluminum expands away from the steel, but in an actual line, the tension of the cable is sufficient to stretch the steel so that the aluminum does not become loose. In actual construction, I doubt if you will find separation of the aluminum from steel. They will act together as a unit with this exception: with changes of temperature the stress passes from one to the other. The hotter the metal, the greater the stress in the steel; the colder the metal, the more stress in the aluminum.

In closing my paper: the design of the bird guards has been a matter of trial and error. We equipped a portion of the line with what is known as Mr. Barre's bird pans. The bird pans consist of a horizontal tray of metal lying on the lower member of the top crossarm, the idea being that it would form an efficient mechanical shield between the bird and the conductor. Apparently they have worked quite successfully, the only objection being that they are rather expensive, and unless they are very well anchored to the members of the tower, the ordinary vibration sets them imitating big drums, so that there has been some complaint from real estate agents trying to sell property in the immediate neighborhood.

There is another kind of bird guard which is simply an exaggerated saw-toothed, galvanized iron, the points being perhaps 1½ or 2 in. apart and with a height of some 6 in. so that it is a very acute point which is not comfortable to the bird. These were fastened along the members of the tower for a distance of approximately 5 ft. on each side of the center conductor. This line, by the way, is of horizontal construction, and similar pieces of metal were fastened to the sloping portion of the crossarm in the outer positions.

When we first put up these bird guards as mentioned in the paper, we didn't know what a clever fellow the bird was, and we put up one kind of a guard to protect the place we thought he was going to roost upon, but, driven out of there, he took the next best thing. He even goes so far as to climb into a little piece of 6-in. channel which is underneath the main crossarm, a piece only about a foot long, which is a part of the structure from which the center string of insulators is hung. When prevented from getting on the main body of the crossarm, he flew underneath and got into this little cage place, so we have had to protect that too.

Regarding the residual currents and the situation of the transformers and auto-transformers, the information Mr. Cone asked for can be given him, but it really will not be of very much use since it refers to a line which is not transposed. We have been trying ever since the line was built to find time to transpose the conductors, but we have never had time to take the line out of service and do this work. As soon as the third line is in, we expect to be able to take out the other two lines, one at a time, and transpose them. This will balance them, statically, against ground, and will reduce to a considerable degree that residual current.

THE LINE OF MAXIMUM ECONOMY[1]

(KIRSTEN AND LOEW)

SEATTLE, WASH., SEPTEMBER 16, 1925.

C. E. Carey: It seems to me that the authors have laid down a premise which at this time I would like to question, whether or not it is the fundamental premise of this paper.

I question the statement which reads: "Therefore, the basic assumption is made that for maximum economy all lines should be operated at an average voltage slightly below the critical disruptive value of the conductor used. To make the assumption more specific, 90 per cent of the critical disruptive voltage will be assumed as the correct value of the average line voltage in all cases."

When we consider an economic transmission line, we balance the annual cost against the losses, or, in other words, we strive to develop a line which gives the lowest annual operating expense per year, including interest, depreciation and losses. Why is there no voltage above the critical corona voltage which is the economical voltage? The losses due to corona enter into these annual charges as a fixed charge and therefore have a proper place in arriving at an economical voltage.

I would like to ask the two gentlemen if they have established, as a fact, that the economic line voltage is always under the critical corona voltage.

F. G. Baum: I should say the authors started out with the wrong assumption; that is, that the voltage is fixed. If you follow the theory given, in every line you would have a voltage depending on the length of the line. Can you imagine the maze of voltages we would have in the country if such a principle were followed? You can fix the voltages and then, by taking aluminum or copper lines, get exactly the same economic results. That is shown by the City of San Francisco, which put in a line recently of 150,000 volts for 150 mi. They used that old factor of 1000 volts per mile. There has been no good reason for that rule. Someone said it one time, and it was untrue then, and has been untrue ever since.

They applied Kelvin's law to the design of this line, and the work done in the paper I think is very commendable, but Dr. Kelvin didn't say what values to use for the line loss. I would like, when they get ready to build some of these lines, to supply the line losses at very much reduced figures, under the figures they give. The figures which we use in California are practically one-half the line loss per kilowatt hour that they use in this paper. That, I think, will make a material change in

the results. The cost per kilowatt-hour of line loss decreases and not increases with length of line.

A diagram similar to theirs on regulation has been in use in my office for a good many years, and a similar diagram was recently published in the *Electrical World*. The fundamental basis of it was given in May, 1900, in the A. I. E. E. JOURNAL.

E. A. Loew: I wish first to reply to Mr. Carey's question with reference to the 90 per cent corona factor. I may point out in answering that we don't care what factor is used, so long as he uses some factor, be it unity, or a little more, or a little less. Every engineer is free to choose whatever value seems best. It doesn't affect the general scheme outlined. It is difficult for me to see, however, how you are going to increase the economy of a line by increasing the voltage above the corona value, because the corona loss is proportional to the square of the overvoltage, and as the voltage is increased above the critical value the loss soon becomes excessive. We have made no test to determine whether introducing corona would yield a value for the most economical voltage, above the critical disruptive value for the conductor used. It hardly seems necessary to make such a test.

If I interpret Mr. Baum's statement correctly, he made the assertion that we predicate a voltage which is proportional to the length of the line. That is exactly what we do not do. If Mr. Baum will examine equations (**21**) and (**64**), he will find that there is no such thing involved. In equation (**64**) the length of the line is involved only as a factor in the last term of the denominator, and then only to the extent of the 6th root of $(1 \div L)$. In the numerator is involved the root-mean-square kw. transmitted over the line to the one-third power. Therefore, the amount of power that is transmitted over the line is by far the greater influence, and the length of the line has very little to do with determining either the conductor diameter or the voltage used.

In other words, if one were to transmit 100,000 kw. for example, over a single line 100 mi. long, it is quite likely that the voltage required would be higher than for 50,000 kw. transmitted over a 200-mi. line.

A statement was made relative to the assumed power loss. I wasn't very sure what the speaker had in mind, but it is true and it is stated very emphatically in the paper that any assumption as to power loss on a transmission line as a basic criterion upon which to determine the proper design of the line is more than likely to be erroneous. It so works out in these problems that we have used as illustrations, that the percentage power loss increases with the length of the line. In other words, an economic line for 100 mi. would probably have a power loss, (an average power loss) of about 4 or 5 per cent. The 200-mi. line might have 7 per cent, and the 300-mi. line probably 9½ or 10 per cent, but the loss does vary with the length of the line.

With reference to the diagram which is alleged to have appeared in 1900, I wish to state that many diagrams have appeared from time to time, among them one by Mr. Baum. The diagrams in this paper have, we believe, certain new and valuable features. We offer no apologies for the diagrams.

IMPROVEMENT IN DISTRIBUTION METHODS[1]

(HOOD)

SEATTLE, WASHINGTON, SEPTEMBER 17, 1925

R. E. Cunningham: I have particularly noted the first paragraphs of Mr. Hood's paper regarding the necessity of thoroughly grounding secondaries and I want Mr. Hood to know that I concur with him in his statements.

I believe that too many of us have been content to drive a pipe or two connected to each secondary system and call it good enough. We all know what may happen to such grounds, particularly in dry districts. I think we should arrange through local ordinances to have a ground connection made at each customer's service which would be installed at the same time the house is wired by the contractor. This should be a water-pipe ground.

Now, as to using a common neutral, Mr. Hood, no doubt, has a condition where, as he has stated, his plan has worked satisfactorily. Whether it would work under conditions obtaining in Southern California is a little doubtful. We have a long, dry season and a good ground is hard to get: in some cases it is impossible. There are very few districts where we have continuous water-piping systems and in some cases cement is used in making the joints in the pipes.

Thus far on our 4-kv., four-wire systems we have adopted the practise of grounding the primary neutral at frequent intervals, generally by the use of a driven pipe. We have not tried the plan of using the same wire for a secondary neutral.

I might say that in most cases we do not have secondary systems continuing throughout the primary circuits, so that possibly there is not the same opportunity for economy as exists with Mr. Hood. With the system as I stated, using the driven-pipe grounds connected to our neutrals, we have had a number of cases during the dry season when the phase wire has fallen and lain on the ground without kicking out the circuit breaker at the station. We are particularly concerned as to how to take care of such a hazard.

We have recently built a new substation in a district where the system was being changed over to 4-kv. four-wire and are trying out the scheme as shown in Fig. 1 herewith. Here the neutral wire is isolated from the ground except at the station and there the connection is through a current transformer, the secondary of which is connected to an ammeter and relay. This relay in turn can actuate an alarm bell. Any current in the neutral due to unbalanced load will not indicate on the ammeter or cause the relay to function, but any current returning to the station from a phase wire which might fall on the ground must flow through this current transformer.

The current transformer is provided with taps and the relay so adjusted that it will operate when one ampere flows through the ground connection. Tests have been made which show that about that amount of current would flow when a coil of bare wire connected to a phase wire was thrown into a patch of green grass at a distance of about one mile from the station. Normally adjustments are for a much higher current so as to protect against a full ground and then once each hour the operator makes a test using the one-ampere adjustment.

We hope with this device to discover cases of phase wire on the ground under such conditions as not to cause sufficient return current to trip the circuit switch.

I would like Mr. Hood's advice on our situation and also wish to inquire whether with a phase wire down he usually gets enough current through the ground on his 4-kv. circuits to release the circuit switch.

E. R. Stauffacher: The ground relay mentioned by Mr. Cunningham will ring an alarm only when a current of one ampere or more goes back to the station from the line lying on the ground, whereas, our test indicates that only 0.3 or 0.4 ampere actually flows back to the station when a line is down on a 4000-volt distribution circuit about one mile from the substation. This, or course, applies to the dry soil condition. The equipment would indicate properly and give an alarm if the wire happened to be lying in green grass or in wet soil or against a green tree. However, there is every reason to expect that it will be rather difficult to develop equipment which will indicate when a line is lying down in dry soil or on a concrete or asphalt pavement. This leads me to believe that it would probably be better practise to install numerous grounds along the distribution line in addition to the ground at the substation, and to make every effort to see that the circuit breaker tripped out in case a wire dropped to the ground, rather than attempt to develop some type of ground detector which would indicate this hazardous condition.

1. Complete paper available in pamphlet form only.

C. A. Heinze: In Los Angeles, we have made use of grounds to water pipes for some years past. Our method is to select at least three services on each secondary and ground the neutral of each service to the local water pipe on consumers' premises.

It seems that ten or fifteen years ago the water department of our city experienced considerable trouble and difficulties with electrolysis. I imagine that a number of members know the full meaning of that word when applied to water systems, and the difficulties with electric railroads. To protect itself, the water department in Los Angeles constructed mains with cemented joints, thus preventing the possibility of getting a good ground by attaching directly to the main itself. However, on a three-wire service if we can obtain permission from the consumer, we bring down the neutral, connecting it directly to the water service. For mechanical reasons sometimes we use a piece of conduit, bonding it at each end.

I am a bit surprised to learn that Mr. Hood would like to have us go back to the multiple street-lighting system. It seems to me off-hand that we would be taking a step backward. I remember quite well that years ago we all, more or less, had multiple street-lighting systems, and we gave them up for the supposedly more efficient series system. Now, I find there is a tendency to go back to the multiple system again. I don't know whether the telephone engineers have had anything to do with this or not. At the same time I can't believe that it is a step in the right direction. Mr. Hood proposes and does install a contactor for connecting each lamp to the secondary bus nearest to the location of the lamp. From his paper I gleaned that it will require twelve watts of energy to keep this contactor energized during the daylight hours, and of course, during the hours when the lamp burns, the contactor is out of circuit or de-energized.

In Los Angeles, excluding the ornamental post lamps, we have 10,000 street lights of the suspension type. Now, if the contactor were to be provided for each one of these lamps in order to operate it on a multiple system as recommended by Mr. Hood, our loss in energy, valued at one cent per kilowatt hour would amount in a year to practically $7000. I don't know what Mr. Hood's company receives for energy for street-lighting purposes in his city, but surely none of us in the West are making sufficient money on street lighting to stand a yearly loss of any such amount; in our case, amounting to $7000.

I can't see what the future holds for us if we go to a multiple system. I would like Mr. Hood to explain the reason for going to the multiple system. I have always been given to understand that the multiple lamp, toward the end of its life, greatly decreases in candle-power, while the series type tends to burn at full candle-power until it burns out. I feel that this will result in a large number of lamps being continued in service at reduced candle-power and not being replaced until they actually burn out, resulting in decreased illumination on the streets. I think we, as utilities, should strive to give the public all they are paying for and the best street lighting possible.

M. T. Crawford: I notice that the neutral return path described by Mr. Hood is apparently largely in the secondary neutral grid. I would like to ask if single-pole switches are used or three-pole switches on the outgoing feeders at the substation. It would appear that if single-pole switches were used and single-phase short circuits occurred, opening one or two switches, the neutral would be called on to carry the full-load current of the phase which remained in service, greatly increasing the duty of the neutral path, and I should think increasing the troubles that might come from using only a relatively light-capacity neutral grid.

Rather extensive use is made of fuses in the secondary main for sectionalizing in case of trouble. I would like to ask Mr. Hood what method he has for finding out when these secondary sectionalizing fuses blow. If secondary sectionalizing fuses should blow and no knowledge was had of the fact, they might stay open for some time and interfere with the proper interchange of load current.

Mr. Hood refers to the fact that the primary-neutral return current sometimes will split and take the paths of the secondary outside wires, rather than all go through the common neutral. I would like to ask if he has made any test which would determine whether or not this disturbs the voltage regulation on the secondary at such points. It would seem that it might have considerable effect on the voltage drop on the secondary bus and would affect the consumer's service.

In regard to the underground system, I would like to ask if Mr. Hood has experienced any operating difficulty in connection with the relay contacts. On the underground distribution system in Seattle where a large number of power-directional relays are installed, we have found it necessary to periodically inspect and clean the relay contacts. The gases and other substances in the subways appear in some way to cover these contacts so that they do not always function.

D. K. Blake: I find a large number of people who are strongly in favor of the common neutral and just as many who are strongly opposed to it, but the chief cause for opposition seems to be the telephone interference.

As to the multiple lighting circuit, there are a large number of eastern companies who are going into that, studying it and applying it. I was very much surprised to find in Denver that the business section was supplied with multiple circuits with cascade pilot-wire control.

Mr. Hood referred to his polyphase secondary network for the business section which is a seven-wire system. There is a somewhat different type of system used by a large southern city of about 200,000 population. They have the same idea, that is, they do not want to supply an off-standard voltage to their customers' devices so they take the secondary winding of the transformer and extend it to 133 volts, which gives 230-star volts for the motors, and of course, a seven-wire system.

As to the matter of neutrals carrying load current, you might be interested in knowing that there is one large company which makes the practise of connecting distribution transformers from one wire to the grounded cable sheath and in that way they have the cable sheath carrying a number of amperes of load current.

D. I. Cone: As already stated, the subject of distribution systems is of great interest to telephone engineers: one item in particular in Mr. Hood's paper presented today is of importance from that point of view; that is the question of the use of a common neutral for the primary and secondary ground connections and, also, the question of the multiple grounding of primary neutrals. I shall not undertake a discussion of that problem because we have attempted to cover the subject pretty thoroughly in the paper by Dr. Trueblood and myself.[2]

Mr. Heinze referred to the interest of the telephone engineers in the street-lighting problem. There is a paper by Mr. McCurdy which discusses series street-lighting systems from this point of view[3]. As to the multiple street-lighting arrangement, I think, without having had experience with it, that the multiple scheme would make coordination with the telephone plant much easier.

G. H. Smith: I would like to say a word in discussion of Mr. Hood's multiple street-lighting system. We have been living with an overhead series system in Seattle for twenty years and for the last five or six years we have been trying to find some way to dispose of it. The underground lighting

2. Power Distribution and Telephone Circuits, by H. M. Trueblood and D. I. Cone, A. I. E. E. Journal, December, 1925, page 1353.

3. Induction from Street-Lighting Circuits, by R. G. McCurdy, A. I. E. E. Journal, October, 1925, page 1088.

system in Seattle is multiple, and the lamps are low-voltage, fed by transformers in the pole bases. We are averaging about 4000 hours' life on these lamps. It is hard for us to believe that we should use a 120-volt multiple lamp for that service athough I believe that is the lamp manufacturer's recommendation. We hope before long to install an overhead multiple lighting system very similar to the one described by Mr. Hood. We have been working on it for years, and believe that it will justify itself from the standpoint of safety alone. Also, our figures seem to show that it will be fully as cheap and more reliable.

S. B. Hood: Mr. Cunningham has brought up the point as to whether the common-neutral system was suitable for California. I think probably the best way to find out would be to try it. The main thing in the common-neutral system is to have sufficient neutral copper so that the earth does not form a part of the return, not an essential part. Therefore, if the air conditions are very dry, all that is necessary is to equalize the potential between the neutral system and the earth, so I rather think that the point of safety would be just about on a par with the dryness of the earth. If the earth is absolutely dry, it is a perfect insulator, so if you maintain your neutral at earth potential at the interconnection, you never would get any appreciable difference between that neutral system and the earth, even though the earth conditions give very high resistance.

On the question of the opening of the circuit breakers in case of a fault to ground, I suppose what Mr. Cunningham meant by ground was the conductor lying on the ground. My experience has been that it doesn't make any difference what kind of a system you use, isolated-neutral or common-neutral, you cannot depend on opening a circuit breaker on contact to ground. The artificial ground connection such as a driven pipe, will not have less than 100 ohms resistance. Now, you can readily see that 8 or 10 ft. of 3¼-in. pipe, will not give a good ground. The contact resistance of a wire on the ground may be up in the thousands of ohms. So I don't think it makes any difference; you can't depend on opening the breakers through accidental contact with the earth.

Mr. Heinze brought up the question of the individual house grounds, and the difficulty of getting continuous grounds through the water main. I think that is probably common all over the country, possibly not to as great an extent as in Los Angeles, but you get the benefit of the buried pipe which forms a service pipe from the main, including the section of main in which that service pipe is tapped. So in the aggregate you have a fairly good surface of water pipe in contact with the earth, certainly much better than you could ever expect by an artificial ground. When you interconnect all of those grounds by a system neutral, you can count on pretty good protection.

I am sorry I can't agree with Mr. Heinze about the multiple system being a backward step. We think it is the greatest step forward we have ever made. I have felt for a great many years that the practise of running series circuits, which may have potentials up to 6000 volts, through alleys, and out to every street corner, networking your whole area much more highly than your primary circuits can, comes pretty near to being a crime, and there are probably more accidents to the public and to the utility's operating staff through those high-voltage series circuits, than any of the other circuits you operate. The only trouble in the past has been to get the same efficiency in transmission with the multiple system. That can be solved by utilizing the distribution transformers, and the relay control system. Our experience with the maintenance of candle-power in the lamps has been remarkably good. I have always criticized the series system on a basis that the lamps, unless you break them up, will get so dim that you can't see whether they are burning or not.

Regarding the contactor losses in the multiple system, I think you ought to get the right point of view. You must consider that the series constant-current transformer at best will have only an efficiency of about 85 per cent, whereas the contractor uses 12 watts only for initial action, and as soon as the core rises it chokes the consumption down to 8 or 9 watts. That represents less than 2 per cent on a 500-watt lamp, and in a great many cases a group of five or six lamps may be found on one contactor. You can readily see the contactor losses are almost negligible compared to the losses in the series type of transformer.

The principal advantage we found in the multiple lighting system has been the better service during storm conditions. It frequently happens during a bad storm that lamp outages on the series circuits will run 17 to 20 times as high as on the multiple. As soon as the storm starts you will see the multiple lamps winking like stars all over the city. It can readily be seen with the series system that each accident or effect of the storm which has lit the multiple lamps would have put out of business the series type of circuit.

The question of maintained candle-power is one which I think we shall have to leave to the engineers of the lamp association. We picked the series type of lamp and adopted the multiple system, believing that the series lamp was the best of the two lamps. Now, they tell us that the series lamp was a poor lamp at its best, and we should use the multiple lamp, so I don't know which is right. Experience will have to show. I think, however, that one feature in favor of the series type of lamp particularly in our large cities, is its longer life. They claim series lamps used on multiple system will give 2160 hours' life. We are getting 3000 hours on ours and better, and very well maintained candle-power. They also claim the multiple type of lamp is good for 1300 hours. My experience with the large systems is that if you get 1000 hours life out of it you are lucky.

Now, where you have cars parked along the streets all day and most of the night, when are you going to get a maintenance car up to the ornamental lamps? The men must go around before sunrise, and even then you will find many cars.

Mr. Crawford asked whether we use single-pole or three-pole switches on our feeders at the substations. Originally all our lighting feeders, before we converted to the common neutral, were the two-pole. So the only change we made was to change the original double-pole switches; the two poles were put in series giving twice the breaking capacity. Those circuits, however, were almost entirely lighting circuits and we found that the action was substantially that of a one-wire single-phase circuits. They didn't act as three-phase circuits at all. However, all our three- phase power circuits had three-pole switches, and as we cut to combination feeders, we found the single-pole switch had no advantage, due to the fact that among the other peculiar things we do, we always ground the neutrals of our three-phase power transformers. When you get a single-phase short circuit, the closed secondary delta transfers the short circuit to a very considerable extent to the other two phases, so that all three switches, would go out in the same way as though they were on a three-pole switch. For that reason, as we rebuilt our substations, we conserved substation space by putting in entirely three-pole switches. In the modern substation with automatic closing equipment, it is the fact that almost always a circuit will not lock-out but will burn the fault off.

The matter of locating blown section fuses is largely checked up by periodic inspections made just before the fall peaks. During the summer season most of the load in the interconnected districts being residential load, it doesn't make much difference whether those fuses are in or out, except in some places where the range load is heavy. We make careful inspection just prior to the fall peak, and from then until we pass the overlapping period, the spring of the year, we depend on the customer to let us know when those section fuses are out. Generally he doesn't waste much time in doing so. In other words, our transformers

will carry the load with those fuses out as well as with them in, but the regulation would be very much poorer; therefore, we almost invariably get a complaint from a customer when a section fuse is out.

We have never had any trouble with the effect on secondary regulation caused by flow of current in the neutral. There is under certain rather abnormal conditions a tendency to unbalance voltage, but you must have a very abnormal condition to bring out that effect.

Regarding Mr. Crawford's question as to relays in the underground a-c. system, our condition is possibly just a little different from what he may have in mind in that our transformer vaults are to all intents and purposes substations. We don't have the dampness and the gases found in an ordinary manhole vault. We are particularly fortunate in Minneapolis because we can put vaults under the sidewalk, and they are just as dry as the basement of a building; in fact, they are virtually the front of the basement. We use the same type of relays and equipment as used in the ordinary substation, and they are inspected periodically; in most cases once a week.

In Mr. Blake's remarks, he referred to a system in the South which used 133-volt transformers. That is the type of transformer with the 133-volt secondary tapped at the 115-volt point. We had considered that, but the objection we saw was that it made a semi-special transformer which is objectionable from the standpoint of simplicity in warehouse stock were it is necessary to stock one type of transformer for overhead distribution and another for underground. If the underground required a special type of transformer, probably that tap would be all right, but in our case we have adhered to standard equipment throughout.

THE STUDY OF IONS AND ELECTRONS FOR ELECTRICAL ENGINEERS[1]

(RYAN)

SEATTLE, WASHINGTON, SEPTEMBER 17, 1925.

R. W. Sorensen: Professor Ryan says, "There are two varieties of electrons, positive and negative." On this he can find much authority; in fact in his book, "The Electron," Dr. Millikan speaks of positive and negative electrons, but I much prefer in this particular to follow the practise of those who define the electron by saying it is a cathode particle such as is found in the cathode rays. I choose this path of thinking about electrons because we all know something about cathode rays. These rays have been found to be made up of negatively changed particles, and the particles are called electrons.

This definition makes the electron a single individual, always negative, rather than twins, one positive and one negative, and it is, as a consequence, more easily recognized. If the electron cannot be a twin, we must provide it with an affinity from which it wishes never to be separated, and in this form of nomenclature the term proton has been applied to the same individual that Professor Ryan has called the positive electron.

More frequently than not, these electrons and their protons are found in large groups, but, in the case of the hydrogen atom, they are alone, this atom being made up of one electron and a single proton nucleus. That points out one question to which we might refer in Professor Ryan's paper where he stated, I believe, that the positive electrons were not found alone; but this is the one exception. If one of these hydrogen atoms encounters a disturbing influence, such as an electric field, powerful enough to detach an electron, the electron becomes free and there is left the single proton.

Proceeding in the direction of complexity of structure, we could discuss the helium atom which has two electrons attached to a nucleus that appears to have four protons.

When one or more of these electrons or negative particles is taken away from an atom the remainder behaves in such a way as to indicate that it has a positive charge, and is known as a positive ion. Thus atoms become ions when they have a deficiency or excess of electrons.

I see no reason why protons as defined cannot exist in a free state in a hydrogen arc, but it is, of course, true that compared to the number of times one can find free electrons, such an occurrence is very limited.

I had planned to question the statement that "under all ordinary conditions approaching quiescence, free electrons adhere to atoms, otherwise neutral." But now, although a number of physicists think they are free, I am inclined to think that we shall get into less trouble if we take Professor Ryan's statement that these electrons are likely to attach themselves to neutral atoms, making them negative ions.

Something is said about electron travel. In regard to that, when we measure an electric current as so many amperes we are measuring the sum of the positive and negative ions passing through the ammeter.

I should like to suggest that perhaps as engineers we would clear up Professor Ryan's statements as to the movement of electrons, by saying that the electrons or ions may be moved mechanically, electrically or magnetically; that is, you can move them by mechanical means by placing them in what we call electrostatic field, or in a magnetic field. I know that is exactly what Professor Ryan intends to say, but I think it would be better to say magnetically rather than electromagnetically.

On the second page Professor Ryan has divided conduction into three groups. I think we should add something to these. An electric current made up of these ions or electrons will also travel through a vacuum, and I do not believe that this has been included in these three sections. Also, I am not quite sure that these three groups as listed show conduction through an arc.

To the paragraph at the top of the second column on the second page I am inclined to add the idea that every atom has electrons; therefore, how can one have a fluid which does not have atoms and hence does not have electrons? Correspondingly how would it be an insulator under Professor Ryan's definition?

Considering practical engineering application, I am one of the many who have a feeling that air, pure and unadulterated, if not a nearly perfect insulator, is at least a pretty good one and one which will serve us for a long time. In the final analysis, all our transmission lines are air-insulated, the porcelain bead chains with which we decorate our transmission towers being, after all, only decorative suspenders which serve to keep the lines from falling. The insulator is the air.

I think the reason Professor Ryan and I differ in this is because he says a thing is not a thing unless it is at least 99.44 per cent pure. Air, then, is an insulator just as oil is an insulator. If we introduce into the air, free electrons or ions, the air as an insulator becomes defective in exact proportion to the amount of impurity introduced. In undertaking our engineering problems we call oil an insulator. It never is a perfect one and it ceases to be an insulator at all if moisture is added to it, its value as an insulator decreasing in proportion to the amount of water added.

I might also add that in the sense which Professor Ryan has spoken of an insulator, a vacuum is not an insulator. Current can and will go through it. To my way of thinking, a high vacuum is an insulator, but it is not a perfect insulator; therefore, Professor Ryan says it is not an insulator.

When two conductors are brought very close together, a potential of 1,000,000 volts. per cm. or even greater potentials may be required to break down the gap. Also, cold electrodes in high vacuum require potential gradients of this magnitude as ionizing potentials, but charged electric conductors in air at sea level and separated practical distances will arc over one

1. A. I. E. E. JOURNAL, SEPTEMBER, 1925, p. 964.

to the other if the potential gradient in the air between them is 30,000 volts per cm.

However, on this point I must assure you that though we are using different words, Professor Ryan and I understand each other thoroughly in this matter, and in conducting experiments involving these things, we would use in many cases the same strategy and anticipate the same results.

C. E. Magnusson: There is, one factor—in fact a vital factor in the electron theory—the physical characteristics of which are seldom discussed while the attention is focused on the several forms of mass units involved. I refer to the electric charge. What is the innate nature of positive and negative charges, which take possession of, or are possessed by, electrons, ions, protons, corpuscles, or by whatever name the mass units may be designated? How can the charge, if located on or attached to an electron or other mass unit of definite size, produce action at a distance or be attracted or repelled by other charges attached to far away mass units? What is back of Faraday's lines or tubes of force? May I ask Professor Ryan to give us his concept of the electric charge?

C. L. Fortescue: I think one of the reasons why electrical engineers have difficulty in following and applying the electron theories is because it is the first time they have come up against the subject of statistical mechanics, a subject with which physicists have become very familiar in their study of the dynamic theory of gases.

Now many laws of physics, dynamics and physical chemistry were found before the kinetic theory of gases was well established, and these laws prove to be true under practical conditions.

Electrical engineers have been accustomed to think of air as an insulator which breaks down, under ordinary conditions, at about 30,000 volts per cm. This, of course, is a very convenient way of looking at it, but we know by the electron theory that this isn't at all true except under certain specific conditions.

The electron theorists tell us that the air will break down at any point where the rate of ionization and the rate of recombination are equal. I believe the rate of recombination depends upon the mobility and the rate of ionization depends upon the density of the air and also upon the total value of applied potential or the difference of potential between electrodes; but we have two quantities there that have to be taken into account. As a consequence we find for a very small separation, as Mr. Sorensen points out, a breakdown strength of the order of 1,000,000 volts per cm. In a larger space the breakdown strength of the air becomes less and less. In the ordinary spaces the engineer uses, we find it averages around 30,000 volts per cm.

In Professor Ryan's paper, I was a little disappointed when I read his remarks about the three sorts of insulators. Unfortunately we are likely to generalize and think of these things practically as hindering our methods of insulation. For instance, Professor Ryan makes his statement in such a way that one would think, reading it superficially, that barriers were absolutely indispensable in connection with all insulators. We know by actual experience if proper care is taken to prevent the formation of corona, or putting it in terms of the electron theory, when local ionization is avoided, we can use air without applying barriers, and the strength of the air will follow the avarage law which I have mentioned, breakdown taking place at about 30,000 volts per cm.

Certain conditions occur when the bounding surface between solid dielectric and air apparently does not follow the law of breakdown in air. I think these discrepancies have been attributed to the effect of the absorption of gases or moisture on the surface, but if you have a perfectly clean surface of proper conformation, the path along the surface will have the same breakdown strength as the air has.

I should like to ask Professor Ryan to clear up this difficulty in the interpretation of this paper. We are sure as engineers that the air is still a medium for insulation.

F. G. Baum: For many years (since 1911) Dr. Ryan has exhorted us to study the electron. I am here as a missionary today to try to help show the importance of studying the electron. For many years the subject of electrostatics has been taught in schools. In my opinion, there is no such subject as electrostatics except as you get down to an extreme vacuum where you have no ions injected into the vacuum; otherwise you have "electron mechanics," and I believe in a very short time you will find that our textbooks will be rewritten and the term "electrostatics" practically eliminated. It is wrong and we must get another proper term and realize that we are dealing with objects moving at very high speed and causing entirely different conditions from those which we thought true when we studied electrostatics.

Ordinarily, we take two bodies and draw lines between and say that is an electrostatic field. It is an electrostatic field only because electrons are moving from one of those bodies to the other; and our higher voltage insulation problem is dependent on a knowledge of handling this electron flow.

H. J. Ryan: Replying to Professor Sorensen: I can accept, if necessary, the use of *proton* in lieu of *positive electron* as proposed by some physicists. It is simply a choice of terms. Personally, however, I like Doctor Millikan's use of *positive electron* to emphasize the fact that all matter is substantially made up of cathode and anode particles. As implied, it is true that experimental facilities are as yet more abundant or convenient for the liberation of cathode particles than for anode particles. These cathode and anode particles surely are twins of just the character referred to. They carry elemental charges equal in amount and opposite in sign. The positive electron or proton is much smaller in diameter and has a correspondingly greater mass than the negative electron. The same elementary electric field or charge centers in the electron whether positive or negative,—the one and only known difference being that of direction or polarity. I do not feel that the use of the term "proton" is adapted to the presentation of these facts as well as the term "positive electron." It is helpful to have been reminded of the stripped hydrogen atom which can be produced and which must behave as an isolated positive electron, proton, or anode particle as we may variously call it.

I quite agree with the idea put forth in regard to the movement of ions and electrons mechanically, electrically or magnetically. However, it should be remembered that they may be moved also by any combination of these agencies. For example, ions in the air that is blown along between the poles of a magnet and between metal plates maintained at a difference of potential, will be moved mechanically, magnetically and electrically. It may be that it is not helpful to compound these terms and say that the ions were moved electromagnetomechanically. I am quite agreed to say that they were moved electrically, magnetically and mechanically.

I am glad to accept *vacuum* for a place in the list of electrical conductors. I had left it out originally because in the first place a vacuum is not anything, anyway in the ordinary sense and, therefore, can not assist or hinder the migration of ions or electrons; in the second place, as Mr. Wood brought out in the talk referred to, as soon as ions or electrons are admitted to the vacuum it may in a sense be thought of as having ceased to be a vacuum.

I can see no difficulty with the statement "No fluid of any sort pervaded with a supply of ions or electrons can properly be regarded as an insulator. Correspondingly, every fluid in which ions and electrons are absent must function as an insulator." Of course, each molecule of neutral transformer oil is made up of complete or neutral atoms that in turn are made up each of an equal number of positive and negative electrons bound together, forming neutral aggregates. Such oil is not a supply of ions and will not conduct under an impressed electromotive force of moderate value. If, however, the oil con-

tains impure water in suspension it is pervaded with a supply of ions and will conduct.

I cordially admit the powerful revulsion of feeling that must come to one when first confronted by the fact that it is the wall of the metallic conductor when immersed in air that is really the insulator and not the air. Take away the air, as one may do in a vacuum, and the conductor will be insulated just as well as before. This is the fact that made me doubt the wisdom of putting "vacuum" in the list of conductors. It does not really matter, though, as long as we can agree as to the circumstances in which it does or does not conduct. Years ago, when the idea prevailed in my own mind that air is one of our best insulators, with dielectric strength greatly enhanced by compression, I undertook to provide a powerful dielectric by means of air compressed to 1500 lb. per sq. in. I was greatly perplexed by the results because I was wholly unaware of the fact that air will permit ions to pass through it freely if one will but provide a source thereof, such for example as a hot carbon electrode. We did not know then, as we know now, that in all ordinary circumstances electrons cannot escape from the wall of a conductor which is the basic reason why we were made to believe that the air was the real insulator. Furthermore, we did not know then, as we do now, that at extraordinarily high electric intensities at the surface of an electrode conductor (1,000 kv. per cm. approximately) electrons or ions will escape from the wall of the conductor and be driven freely through the air to the opposing electrode where they will be discharged. With a knowledge of these facts twenty years ago we would not have been perplexed by the anomalous behavior of air as an insulator when put to a real test.

I cannot agree that it is a matter of degree to be covered by such a small item as the departure of 99.44 from 100. It is not a question of purity or impurity any more than it is in the case of water. Water will conduct as long as it has ions suspended in it. Being a fluid it ceases to conduct only when the supply of ions has been eliminated. And this will cover also the reference to oil.

Doctor Magnusson asks the question "What is the innate nature of positive and negative charges which take possession of or are possessed by electrons, ions, protons, corpuscles or by whatever name the mass-units may be designated?" This question and the form in which it is put are helpful even if one has not a ghost of an answer. I can only discuss this question, I cannot begin to answer it. I can only offer what appears to me to be a reasonable conjecture in regard to the perhaps most important attribute of the electron. This is that all electric fields are made up of unit-fragments alike in constitution. Each field fragment terminates on an electron from which it extends radially and expands uniformly, and so far as we know, indefinitely. These field fragments are the same, whether positive or negative, differing only in polarity and in radius of the electron surface at which the field terminates, being much smaller for the positive electron which must, therefore, have a correspondingly greater mass, the measure of the energy that was used in the extra concentration of the field. Whatever else they may be, electrons are surely these field fragments. All greater electric fields are merely aggregations of these unit-field fragments. The electric intensity through any field volume is the vector sum of the radial field fragments attached to the electrons that constitute the charges to which the field is attached. Maxwell understood the composition and resolution of electric fields and taught us to locate "tubes" of electric force by drawing diagonals through the parallelograms that are formed by the radial lines which represent the electric fields that extend uniformly in all directions from charges located at a point. It is the vector composition of superimposed fields terminating upon the positive and negative electrons that forms the "tubes of force" of an electric field. It is in the presentation of these facts that I find the term *positive electron* more helpful than *proton*.

It is also helpful to have Mr. Fortescue emphasize the importance of *statistical mechanics*. I trust that all who are interested in the new knowledge will read thoughtfully what he has said. He also refers to the extremely short space that must exist between metal electrode faces before electrons will leave them and the vacuum, or gas-filled space between them, will become conductive. If the fact is allowed to stand in that light I fear we shall give our more general audience the impression that this action is the result mainly due to the close proximity of the metal electrode-faces. In fact it cannot primarily be due to the nearness of such faces as Hayden and Steinmetz have shown in their A. I. E. E. paper on the dielectric strength of the vacuum.[2] The preparation of my paper was only possible by the use of old terms with new or modified meanings. I had to count, therefore, upon precisely such disappointment as that of Mr. Fortescue because I have referred to air as a conductor instead of as an insulator. I have no thought of proposing that we stop calling air an insulator. What I do want to see established is a better understanding as to how it can be made to conduct abundantly. With that, and with more of a background in the subject which will come with experience, the choice of terms with no doubts on important difference, will be readily accomplished. I am a hearty advocate of the high value of the *Fortescue principle* wherein air insulation barriers of powerful solid dielectrics are applied, having boundaries coincident with those of the tubes of electric force in the air adjacent. Such barriers displace the air in regions of dense electric fields that would otherwise ionize and afford prolific conduction. We do not differ as to the facts and in the end we shall have put new meaning into old terms or adopted new terms by which all who use them will apply helpfully the new knowledge of these things.

Mr. Baum has declared rightly that electrostatics are hopelessly inadequate for understanding and for effective control of electrical states and actions. This I know to be the case even though we cannot agree as to facts when he says that a quiescent electric field between two charged bodies is such "because electrons are moving from one of these bodies to the other." Of course, this brings us face to face with the age-long problem of "action at a distance" and my question to myself is: "has Mr. Baum made some progress toward the definition and solution of that problem?" Most of us have not,—we face a high wall and cannot see what is beyond. To me the static electric field between two bodies is the composition of the two field aggregates of opposing polarity that terminate on the corresponding free positive and negative electrons that are bound to the surfaces of such bodies.

SOME FEATURES AND IMPROVEMENTS ON THE HIGH-VOLTAGE WATTMETER[3]

(CARROLL)

SEATTLE, WASHINGTON, SEPTEMBER 17, 1925

R. W. Sorensen: When I first saw the diagram of connections shown in this paper I was awed by the apparent amount of large apparatus necessary to construct such a wattmeter. However, I have had the opportunity to stop at Professor Ryan's laboratory and became acquainted with the equipment described in this paper. An acquaintance with the equipment eliminated the impression of bigness which I had received from the diagram and which was perhaps due partly to the high voltages which the equipment will measure. In place of this impression I received a definite picture of the cleverness exhibited by Mr. Carroll and Professor Ryan in handling this problem. For example, the transformer of three windings and a split core, which seems in the diagram to be so large, is actually very small, in fact, it can easily be held in one hand.

2. High-Voltage Insulation, by J. L. R. Hayden and C. P. Steinmetz, A. I. E. E., TRANSACTIONS, 1923, page 1029.

3. A. I. E. E. JOURNAL, September, 1925, p. 943.

The water column, about 16 ft. long, is so arranged between the shielding plates at the ends as to occupy a space approximately 3 ft. in height. The small transformer and the indicating instruments are all mounted on a small table surrounded by a wire cage the dimensions of which approximate 4 ft. high, 6 or 8 ft. wide and perhaps 12 ft. long.

With this knowledge, I found it much easier to read the paper and appreciate what has been done in Professor Ryan's laboratory toward producing practical wattmeters and voltmeters for high-potential measurements.

H. V. Carpenter: Mr. Carroll mentions the integrity tests by which he established the fact that he was able to read with accuracy loads of a watt or two, with a voltage of 150,000. It seems to me the condition is so critical there that a word in relation to his method of establishing the integrity would be interesting. Also regarding the formula given for the resistance of the water column, I would like to ask whether he established it over a wide range of densities and for any materials except common salt.

J. S. Carroll: Ordinarily the man in a measurements laboratory thinks of errors in measurements as a few tenths of a per cent. However, in this case where we are measuring one watt of power at 150,000 volts and the apparent power is of the order of 6000 watts, I frankly admit that we are very well satisfied with an accuracy within 25 per cent of true values. As the load increases the accuracy greatly increases so that at 40 watts we expect the error to be not over two or three per cent. One of the integrity tests used is described in the present paper, that is the double-conductivity test. Another test is described in the Oct. 1924, A. I. E. E. JOURNAL in the paper on Power Measurements at High Voltage and Low Power Factor, by Carroll, Peterson and Stray. In this test a shielded resistance was inserted in the connection to the line, the value of this resistance was known as well as the line charging current through it from which the power absorbed by it was computed; this increase in power was also measured by the wattmeter. The agreement between the results of the two determinations was very satisfactory. The double-conductivity test was also used in connection with the above test.

In regard to Professor Carpenter's second question, I might say that we have so far tried only a common salt solution and have not gone farther than checking the formula given in the paper in an overall way for the purpose of finding any serious error. We measured the cold resistance of a solution and then calculated what the hot resistance of the water column should be, this result agreed very well with the value obtained under actual operating conditions. On some of these things we wish to make a closer follow-up as soon as we have time.

INDUCTION FROM STREET LIGHTING CIRCUITS-EFFECTS ON TELEPHONE CIRCUITS[1]

(McCURDY)

SEATTLE, WASHINGTON, SEPTEMBER 18, 1925.

R. R. Cowles: The present tendency of the Pacific Gas & Electric Company is toward the use of small series street-lighting loops with incandescent lamps only. These series loops are 6.6-ampere and are supplied from a multiple-series constant-current transformer installed on the pole in the same manner as any other distribution transformer. These constant-current transformers are of the moving-coil type, fundamentally similar to those formerly used inside of stations. In size they range from 5 to 20 kw. each, depending upon the average size of the series incandescent lamps which are connected to the circuit. It is the aim to avoid long loops and to restrict the number of lamps per circuit to approximately 60.

These transformers are connected on the primary side to a 4000-volt, four-wire, three-phase, star-connected feeder circuit, said circuit being switched from the substation just as any other 4000-volt commercial feeder. Where the primary neutral is available no additional neutral is extended for the street-lighting feeder. Single-phase lines are run in various directions to supply the territory in the same manner as single-phase lighting feeders are branched from a three-phase feeder for commercial light and power consumers. The effect of the above arrangement is greatly to improve the reliability of street-lighting service through the elimination of long series loops and the resulting reduction in potential on these series loops. Multiple 4000-volt feeders have proven their reliability on the system of the Pacific Gas & Electric Company; hence no new features are involved in this type of feeder circuit. The constant-current street-lighting transformers are furthermore removed from the substations, thereby providing room for other apparatus which cannot conveniently be placed outside of the station.

The 6.6-ampere series street-lighting incandescent lamps are standard for 4000-lumen lamps and less. This is a slight departure from previous practise which indicated the desirability of using series transformers or auto-transformers with lamps larger than 2500 lumens. An improvement in lamp manufacture, however, has made it practicable to use 4000-lumen lamps at 6.6 amperes. Lamps larger than 4000 lumens are operated at 20 amperes, necessitating the use of series transformers or auto-transformers installed on the same pole or in the same fixture which supports the lighting unit. The film cut-outs are used with all 6.6 ampere lamps, operating without auto-transformer or series transformer.

The use of series circuits with currents in excess of 6.6 amperes has been considered by the engineering department of this company but no action has as yet been taken. Small series loops supplied from individual constant-current transformers, with lamps of higher intensity spaced fairly close, would permit of operation at 15 or 20 amperes if the characteristics of these lamps demanded it. Consideration should also be given to methods of switching street-lighting circuits from a remote point which would make possible the use of even smaller loops and considerably simplify the apparatus involved therein. There are a number of types of remote-control apparatus already developed and a number more in process of development. It appears to the writer that the use of radio control for this purpose might be worked out to a practical and economic application at some future time.

C. A. Heinze: Any power engineer who has had relations with the American Bell Telephone Company will notice that the telephone engineers all tell the same story. The main thought in all of their papers is cooperation between the power engineers and the telephone engineers.

I want to state, first, that the electric utilities want to cooperate with the telephone company. We recognize the fact that we have mutual services to render, but I should like to ask Dr. Trueblood just how far the American Bell Telephone Company will go in cooperating with the electric utilities in sharing part of the expense in safeguarding the telephone companies' equipment.

S. B. Hood: Mr. McCurdy recommends some of the usual remedial measures, principally isolating transformers. That is the 100-per cent remedial measure of telephone engineering, and in most cases it is a 100-per cent remedial measure, but in very few cases is it the measure which the power man wishes to adopt. It adds to the investment, adds to the losses in the system, more or less interferes with the regulation, and has a great many objectionable features.

Another recommended cure on series circuits is the straight-series lamp. That is very nice until we get to the higher candle-power. We are all developing "white ways" that require higher densities of lighting. Therefore, recommending the type of lamp which the lamp manufacturers are not prepared to furnish is looking far into the future.

It seems to me that possibly a better recommendation which they could make—particularly since Dr. Trueblood is so enthu-

1. A. I. E. E. JOURNAL, October 1925, p. 1088.

siastic over the multiple system—the better cure where inductive exposure is used, would be to change the lamps in that particular exposure to multiple, using a series relay for controlling. Of course, the recommendation for closed loops and balancing the lamp on a loop is very effective, but when you put a series street-lighting system with both wires looped on the same street, as far as the investment goes, it is practically getting back to a multiple system.

It seems to me, however, that in all these papers the indication is that no matter how far apart our past differences of opinion have been, we are all gradually coming closer together; the telephone men and power men are gradually getting down to a uniform system which I think is a very promising outgrowth.

R. G. McCurdy: The tendency of the development towards the use of smaller series street-lighting loops as described by Mr. Cowles in his discussion of the Pacific Gas and Electric Company's practises, from the standpoint of inductive coordination, is in the right direction. Because of the smaller number of lamps per circuit and since the constant-current transformer is closer to the lamp load, the length of any given circuit is much reduced and in case of failure of lamps equipped with individual transformers, the length of circuit upon which the harmonic voltages are impressed, and which may be involved in inductive exposures, is much less than when circuits of a large number of lamps are employed. In many cases also, this method of operation would facilitate supplying separately "white ways," where lamps of high candle-power equipped with individual transformers are used, and outlying sections where in many cases, only straight-series lamps are employed.

Mr. Hood referred in his discussion to the disadvantages of the straight-series lamp, especially in districts where high-density lighting is required. As brought out in my paper, however, it is very often the case that these high lighting intensities occur in the densely populated sections of cities and towns, where both the telephone and lighting circuits are in cable. In such cases the occurrence of "out" lamps equipped with these transformers is unimportant from the inductive standpoint. In other cases, where the "white-way" section may be of limited extent, it will often be practicable to connect the high-current lamps to circuits not involved in telephone exposures, having as far as possible, only straight-series lamps on the circuits involved in the inductive exposures.

Many of the difficulties of coordination discussed in the paper are inherent with the series system, and it would doubtless be less difficult to coordinate with multiple systems. The remedy suggested by Mr. Hood, therefore, of changing the lamps in a particular exposure section to multiple, using a series relay for controlling, would probably be an effective one. As far as the incandescent systems are concerned, however, it is felt that the difficulties existing with the series circuit, would be overcome by the use of a reliable form of cut-out with lamps equipped with individual transformers or auto-transformers.

DISTRIBUTION PRACTISES IN SOUTHERN CALIFORNIA[1]

(CUNNINGHAM)

SEATTLE, WASH., SEPTEMBER 18, 1925

F. O. McMillan: There are two questions I wish to ask. Mr. Cunningham states he is using some three-phase, Y-Y-connected transformers; are these core-type or shell-type and if shell-type, has any provision been made for the third-harmonic magnetizing currents in the transformers so connected?

S. B. Hood: In connection with the paper by Mr. Crawford and the one by Mr. Cunningham, we note that they are both using the ground as a stabilizing medium. I think the general tendency is indicated all the way through that that is what we are after. We are trying to stabilize our systems; not to use the ground as a conductor.

Mr. Cunningham brought up the point that in a great many cases the selection of the system was due to local conditions, and therefore, we shouldn't judge one system by that of another in another part of the country. I think that is absolutely correct. There is one point that I have heard in these discussions and papers, and I hear it all over the Coast—you question some particular practise, and instead of defending that practise from an engineering standpoint, somebody will say, "The state law doesn't allow us to do that."

I am wondering whether some of these state laws are not really placing an unjustified economic burden on the public. I think some of these laws probably were passed long before these newer developments were made. A notable instance of that is the law which apparently forbids the use of a secondary rack.

I don't think we pay enough attention to the esthetic appearance of our distribution systems. The secondary rack improves the appearance of the lines very much. Now, Mr. Cunningham, by using the one arm for both primary and secondary, with the pole intervening as a barrier, gets a relatively neat construction, but not as neat as the secondary rack. I think on the point of investment it would probably be an even break, but it seems that where the practise is quite common in one section of the country, and forbidden by law in another, there should be some equalization made.

There is another instance that is somewhat out of line with these papers: I have noticed further down the Coast there is apparently another state law which requires boxing-in an iron pipe on a pole. I have seen some poles where the box around the pole was larger than the pole itself. It is unfortunate that there are laws which require practises of that kind, such transgressions on the esthetics of construction, and sooner or later the utilities are going to be forced underground, before it is economically justified.

M. T. Crawford: Mr. Cunningham's reference to one-arm construction coincides very closely with our experience in suburban territory, where our primary is placed on one end of the crossarm and the secondary on the other. By placing the primary on the street side always, and the secondary wires on the property side, it makes for uniformity and obviates misunderstanding. By hanging the transformers on buck arms, crosswise of the pole, the primary leads come out straight and turn up and the secondary leads come out straight and turn up, making a very orderly arrangement.

In the city we have found it not so practical, due to the necessity of providing space for a number of feeders, and at times having polyphase primary and secondary requiring more wires.

R. E. Cunningham: The matter of third harmonic in the three-phase Y-Y transformer was brought up this morning. This was considered when we first thought of using this type of transformer. The high side of transformers is not grounded. The low side ordinarily working at 460 volts, we wanted Y-connected so as to ground the neutral and not have more than 260 volts to ground from any wire, as a safety precaution. Seldom, is there more than a single service to each transformer possibly not over 25 ft. of wire, so that the third harmonic has never caused any trouble.

Something has been said about the esthetic appearance of pole lines, and attempting to improve the appearance. At best a pole line is not a thing of beauty—we all know that. We can, of course, in some ways help its appearance. Our practise in this regard is, as far as possible, to keep pole lines, particularly in the residential districts, in the rear of property lines, and Fig. 4 of my paper shows such a line. In fact, none but the main lines need be along the streets, and we find this is a great help in keeping down agitation for underground lines in residential districts.

ENGINEERING RESEARCH—AN ESSENTIAL FACTOR IN ENGINEERING EDUCATION[1]

(MAGNUSSON)

RELATION BETWEEN ENGINEERING EDUCATION AND ENGINEERING RESEARCH[2]

(SORENSEN)

AND

A NEW DEPARTURE IN ENGINEERING EDUCATION[3]

(PENDER)

SEATTLE, WASHINGTON, SEPTEMBER 17, 1925

L. N. Robinson: Professor Magnusson emphasizes the point that engineering courses should teach students to think if nothing more. If that is so, why do engineering curriculums, in general, not include courses in the mental sciences, particularly logic and allied subjects? However, it is not my present purpose to argue for or against the inclusion of any particular subject in the curriculums. What should be pointed out is that present conditions indicate a general lack of scientific treatment in the design of engineering curriculums as well as in their application.

We insist that scientific methods should be employed in designing engineering structures. Engineering students have an equal right to insist that scientific methods be employed in designing the curriculums of engineering schools.

When electric generating stations are designed by the same methods that are employed in laying out many engineering school courses, hybrid plants are produced in about the same proportion as our engineering schools turn out bond and automobile salesmen.

In designing an engineering structure, it is customary to decide first what is to be designed, whether it shall be a bridge, an office building, a locomotive or something else. Next we determine which parts shall be of steel, which of copper, etc., then we prescribe methods of fabrication and assembly. In other words, every step from the inception of the enterprise to the finished product is worked out with utmost scientific care.

Is this method followed in designing engineering curriculums and in training engineers? Before it can be said that engineering courses, themselves, are scientifically designed, we should at least first determine what the product of an engineering course should be. Then the elements that should constitute the course can readily be determined, with equal care to deciding how the courses shall be conducted.

Last June, at a commencement the chancellor of a university said that the world is full of people who know all about education except what it is for. This is a challenge to the engineering fraternity and to the engineering schools in particular; it demands a scientifically sound justification for our college courses and especially for our engineering courses. And, since we profess to be scientific in our engineering work, we should be better able than the humanists to answer the challenge. In doing so, however, we must be especially careful not to mistake consensus of opinion for sound scientific truth else we shall class ourselves with those who scoffed at Christopher Columbus because his views differed from generally accepted notions.

J. C. Clark: It seems to me that Professor Magnusson has lost a grand opportunity in his paper to bring out one of the main reasons why we should have research in engineering colleges. He has stressed the value of the educational aspect of research almost exclusively, and has pointed out that it nearly goes without saying that research has an indispensable part in technical education. Professor Sorensen also emphasized very strongly the educational value of research in the colleges. In other words, it is for the good of the colleges and the students that research is carried on in the colleges.

I believe that it ought to be pointed out by Professor Magnusson that the industry needs engineering research in the colleges as much, if not more, than do the colleges. As Professor Magnusson has so emphatically stated, it is true that the large corporations of today have millions to spend in research. They have large and well trained staffs to carry on industrial research, and they carry it on successfully and efficiently. On the other hand a great many of the smaller concerns have very meager appropriations with which to work and carry on research.

It follows that most of us very much need to have a place to have scientific facts revealed. Not only is this true in the smaller manufacturing industries, but it is even more vital for the public to have these independent public laboratories of research which the colleges and universities can so well maintain. It really is not so much the amount of work done that matters, as it is the unbiased check that such laboratories can give upon the results that are revealed and published by the larger corporations.

We do not charge that the large corporations color what they print about their laboratory results, but it is human and almost inevitable that they show the best side of what they find out, and somewhat neglect the unfavorable aspects of those things they are trying to promote.

By doing a very little work sometimes with small funds, the smaller college laboratories can aid industry and the social body a great deal. The exact amount of money at their disposal is not of prime importance although it is true that they need a vastly greater support than they now have.

The professor who has one thousand dollars a year to spend for all his equipment, including its repair, and maintenance, is so handicapped that he can surely do but little with the energy that he puts into the work.

I should endorse what Professor Magnusson said: Industrial establishments of any size that do no research have "signed up for the exit." However, industrial research in smaller establishments may not be carried on because they have not the facilities, and thus they have to depend upon the colleges.

I find much in Professor Sorensen's paper which is of interest. Professor Sorensen starts out with an assumption which surely needs no argument,—that research and engineering are inseparable. Research *must be* a part of engineering education. He takes the same attitude as Professor Magnusson does in pointing out the necessity for it from the standpoint of education. This is self-evident indeed.

Professor Sorensen gives the time honored definition of engineering that I believe was given by Tredgold, the first President of the Institution of Civil Engineers in England; "The art of directing the great sources of power and nature for the use and convenience of man," etc., running through many, many words. It starts as a catalogue of the functions of engineers and thus its weakness is obvious. It can, of course, only begin to catalogue the functions of engineers, but I think that in this very definition, a part of the weakness of modern engineering education lies. Educators and engineers have been more or less hypnotized by such definitions of engineering, emphasis being placed entirely upon the technical aspect of engineering, the scientific, and the big and glorious things to be done by engineers.

I should substitute a very much shorter definition for engineering. I define an engineer as one who directs the economic use of matter or energy. I should let it go at that because I believe that we have among us as great engineers who are directing the destinies of banks or steamship companies, from the standpoint of executive officers, as we have in any other capacity. In other words, technique should not be stressed exclusively in the work that is done in the colleges. There should be a little more emphasis placed on economics. There are very few colleges today that devote any great amount of time to the study of engineering economics. I do not see how it is possible to turn out men with a proper attitude toward

1. A. I. E. E. JOURNAL, November, 1925, p. 1243.
2. A. I. E. E. JOURNAL, December, 1925, p. 1288.
3. A. I. E. E. JOURNAL, November, 1925, p. 1208.

engineering without giving them much study of the principles of engineering economics; not the old social economics, but the engineering student does need a very considerable amount of engineering economics if he ever becomes a true engineer.

I wonder how much deleterious effect this long-drawn-out definition of Tredgold's has had upon engineering education. Has it not hypnotized the profession somewhat into thinking too much about the imparting of information about technical things; perhaps information about the things that can best be learned by the man after he is out of college?

In Professor Sorensen's paper I found one thing with which I think many men in practical research would particularly take issue. That is the standpoint that the undergraduates thesis was wisely eliminated. Professor Sorensen says "it was therefore wisely eliminated." The very next sentence takes the curse off, "But we should not forget that the thesis is symbolical of research—a function which must be the keystone of engineering education if the engineer is to occupy the place for which he is ambitious."

I think that is certainly true. The thesis is needed to support the idea of research, to give some little practise in the methods of research, with the object of bringing out latent research talent in the student.

Professor Sorensen reveals that he has some such idea in a latter part of his paper, since he speaks of the honor sections that are established at Pasadena where the better men are permitted some chance to help in advanced and special work, assisting research men. I think he has there revealed his true attitude toward the research that may be done by undergraduates.

It seems to me that the practise of segregating the students into the ordinary and the extraordinary,—the latter class including these so-called honor men,—is one of the very best developments I have ever seen. I wonder if the real reason for eliminating the undergraduate thesis was not rather the difficulties that were encountered in lack of equipment or lack of time and energy for the administration of the theses than the lack of educational and developmental value in them?

In the paper by Dean Pender and the one by Professor Sorensen there are two quite distinct methods given for the selection of engineering student material. Of the two, I think the one that is the more hopeful is the one that is being tried out in Pennsylvania. The statement that Harold Pender made is quite true; that a boy fresh from high school is usually just a boy,—and I think it does require the few years of college which are a part of the Pennsylvania plan to bring out the judgment of a student and too, to weed out the defective material found among students. It is not defective material except that it is unfit for engineering although possibly very fit for some other, perhaps higher, walk of life. At any rate, there is a great difference among students in their fitness for engineering.

I am somewhat in doubt as to the real value of the physical examination in the Pasadena plan because we have in our electrical history so many able men who might have had difficulty in passing the Pasadena physical test. Is it not going to eliminate an occasional man who has great latent ability in analytical ways?

H. V. Carpenter: This matter of engineering education is one that we shall always talk about I suppose. The Society for the Promotion of Engineering Education is at the present time spending something like a hundred thousand dollars, and I don't know how many dollars' worth of time, in analyzing methods of engineering teaching.

It seems to me that one of the most difficult problems we have before us in that study is this matter of research. You remember that some Roman ruler said, "All right, if we destroy the Greek statuary, we shall send some men out and have it replaced." If we aren't careful, we shall put our research work on that same mechanical basis. I believe that a research man is born. Maybe Dean Magnusson can make a research man, but I am afraid I cannot. I think it is more a matter with us of being able to discover the research man when he comes along in our classes, rather than being able to take an entire class of students and turning them all into first-class research thinkers.

What we need to do is to teach these men to think, and research is only one of the better methods of teaching a man to think. A large share of these boys will never be research thinkers, but they will be very effective engineering thinkers in the ordinary sense of being able to go out and size up a job and put through the best design for it. They may not be research men, but they will be thoroughly useful men on straight engineering propositions.

It is our business to give the man who can do original thinking the inspiration to go ahead to develop his abilities in that line, and to give him a chance in the laboratory. Professor Sorensen's scheme is a very good one; they have adopted a similar one at the Massachusetts Institute of Technology where the honor men are to be given a chance to do as much as they please. The smaller institutions have always done that to a considerable degree in an easier way, having a much simpler problem.

Dropping the thesis was a good thing, I think. I agree with Professor Sorensen on that as a requirement for every student, but for the student who shows interest, I think the thesis should be maintained, and carefully nursed along. We cannot expect revolutionary things from the senior, but perhaps if we start a real genius to thinking he may turn out a revolutionary piece of work in later years.

L. J. Corbett: Doctor Magnussen describes the tendency to take research away from the colleges. I think we need not fear for that, as times are changing. As he states, the large companies are doing a great deal of research, but there is another factor; they also need men—and one of the ways to develop men is through this very research work. I believe this is being recognized by some of our large companies, as evidenced by the assistance which has been given recently, to both the California Institute of Technology and Leland Stanford, Jr., University, in the way of aid in the establishment of high-voltage laboratories. These, no doubt, will give a good account of themselves in contributions to engineering research, and some students will receive valuable training in this field.

From Mr. Sorensen's paper I note that they are omitting the engineering thesis at the institution he represents. However, from the discussion which took place, I see that there is still some opportunity given for the honor men to investigate along the lines of their special inclinations, thus recognizing work on such theses.

To return to Doctor Magnusson's paper, we must recognize the tendency of the companies of today to require specialization in their men. This, I think, has been the inference in the advice which has often been given to engineering colleges to have actual departments of research where some men of the staff could go ahead and do research only, without the change in mental attitude which is necessary when a man does some research and also teaches a group of undergraduates, old, well-known material.

I think the work of the teacher, as Professor Carpenter has stated, is inspirational. I think that if you can inspire a student to make the best use of his faculties, and not to consider his education complete when he has his degree, but to go ahead with his studies and research—you will do a greater work than merely filling him with information and making an encyclopedia of him. I think this quality is particularly exemplified in the man we have with us in the person of Professor Ryan. I believe that all his students will vouch for the inspirational quality of his work

There is one feature in Dr. Pender's paper that struck a discordant note. In one of his conclusions there is the statement that the student should recognize that engineering is a profession, and not a job. That is all very well for us to recognize, but I think we should not emphasize it too strongly to the under-

graduate student, because it is due to such thoughts that we have men who are reluctant to don overalls after getting their degrees. I think a man would get farther in the engineering profession if he were willing to don overalls for a time after his graduation and learn the rudiments of practical work.

J. S. Bates: I once heard an engineer defined as a man who is skilled in the use of the word "approximately." There is really a great deal in that because no matter to how many decimal places we carry our calculations, there is always one more; one or a vast multitude makes no difference. For that reason we should say a very important part of an engineer's education is to determine what percentage of error is to be allowed.

G. S. Smith: In the University of Washington we still have the thesis work scheduled as an elective but it has been virtually discarded, since it is seldom chosen by the student. However, I believe we have found other ways more effective in obtaining the results aimed for in the usual thesis work.

Several of our courses scheduled for upper classmen and graduates, are presented in such a manner that each student, or more often a group of two or three students, selects or is assigned some individual problem to be worked out completely. These prob ems are usually of such a nature that they require a considerable amount of thought, reference work, or experimental work, and thus arouse in the student any latent inclinations toward research work.

As an example I should like to mention a course to which we have paid a good deal of attention in our institution; that of electrical transients as a prescribed course of undergraduate study. In the laboratory part of this course a certain number of topics are assigned to the student for which he must obtain representative oscillograms. This is the more or less routine or practise part of the course. To satisfy the remainder of the requirements, the student must select some problem or topic, acceptable to the instructor, to be investigated by the taking of oscillograms. This problem must be one which has not been previously chosen by other students who have taken the course. Thus their work is, to a certain extent, original.

The response on the students' part is usually more than gratifying. They not only put more energy and thought into this part of the work than in the routine portion, but they also show a strong tendency to attack it from the investigational point of view; that is, they try to find the best method of attack, try to determine the results they expect and then attempt to verify them experimentally, watching all the while for unexpected results. At times, of course, they make complete failures, but more often they are very successful.

H. H. Henline (communicated after adjournment): I wish to emphasize the importance of full and frank discussion of the problems of engineering education by members of engineering faculties as well as by executives in industry. These authors have pointed out some very serious defects which are found in many curriculums.

Most of the engineering curriculums now in effect were planned twenty or more years ago, and changes made since have not altered in any essential details the general plans followed originally. Therefore, we find that most of the curriculums furnish excellent preparation for certain types of work which some of the graduates enter. However, this number seems small when compared with the total. On account of the extremely rapid progress which has been made in many branches of engineering during the past few years, we find ourselves living in a period when the applications of engineering knowledge are so many and diversified in character that any curriculum designed to meet directly certain needs in industry may indeed prepare men in a most excellent manner for those needs, but it fails utterly to prepare them for the great range of engineering problems, both executive and technical, which all graduates will be called upon to solve.

There is a strong and growing tendency to choose executives from the men with engineering training, since the problems which executives in industry must meet are becoming so complex and so closely allied with fundamentals of engineering that great dependence must be placed on the judgment of engineers in order to reach the correct solution. Obviously the schools cannot train men directly for executive positions, since qualifications for such positions depend greatly upon inherent characteristics, and any amount of training would not make capable executives of men who do not possess the necessary characteristics. However, if we wish the engineering graduates who do possess such characteristics to have opportunity to enter the management side of engineering, we must give them the broad, general foundation so absolutely essential.

One of the most noticeable features in the large amount of discussion of curriculums occurring in recent years is the fact that many of our largest employers of technical graduates now wish to secure men who have had a broad training in general subjects and the fundamentals of engineering rather than men who have specialized in a particular branch of engineering. Thus we find that the old situation in which teachers wanted to adhere to fundamentals, and many executives in industry advocated certain specialized courses, is rapidly reversing. Now we find the leaders in industry not only frowning upon specialized courses, but even considering many courses as too highly specialized which are given with the excuse that they are necessary from the standpoint of fundamentals.

In the planning of an engineering curriculum, certain decisions must be made as to the types of activity for which it should prepare men. In the present stage of development it seems necessary to recognize the needs of two distinct groups of students. Those who expect to spend their lives in highly technical design or research must have a more extended technical preparation than those who will be engaged in commercial or industrial phases of engineering. Both groups need a broad foundation on such subjects as English, economics, biology, geology, history, business law, etc., and a thorough training in chemistry, physics, mathematics, mechanics and other subjects which make up the heart of engineering. Such training should be mixed with, and followed by courses giving the fundamentals of all of the principal branches of engineering, and there should be a reasonable amount of time available for elective subjects. Thus far there is no serious difference between the wishes of executives in industry and teachers of engineering. It, therefore, seems that the chief cause of argument is the relatively small group of men who will engage in research and other highly technical phases of engineering. This group must have better opportunities for the development of research ability and specialized study than can be provided in any four-year course which makes necessary the provisions for training in the fundamentals.

It seems that the best solution of the problem may be a four-year course following the general outline mentioned above and leading to some such degree as Bachelor of Arts or Bachelor of Science in Engineering. This curriculum should be so planned that students may have good opportunity to develop powers of initiative and judgment to the maximum extent, and to determine the kind of intellectual effort for which they are best qualified. In order that they may see how they can best fit into that field, it should give them a broad outlook and an excellent perspective of the whole engineering field. Graduates of such a curriculum would be prepared for commercial pursuits and for many types of technical work in which employers prefer that specialization be deferred until after the entry into industry. It is believed that they would advance more rapidly in either commercial or technical employment than if they had graduated from the narrower four year engineering curriculum.

For those who wish to prepare for research and other highly technical branches of engineering, there should be provided opportunities for two years of graduate study. Having completed the liberal four-year curriculum, they would have the

broad foundation which should precede advanced study. The graduate curriculum should be planned with the idea of developing ability in research and permitting specialization in analytical studies, design, or other branches of engineering. Since the number of students in the graduate classes would be relatively small, the effectiveness of the training would be maximum. The progress would be much better than could possibly be made in the same work with undergraduate classes containing many students not really qualified for or genuinely interested in such subjects.

I believe this combination of four years liberal curriculum for all and two year graduate curriculum, for those who are properly endowed for and desire it, would result in producing men better qualified to take their proper places in the world than are those who complete most of the present-day curriculum.

All engineering students should realize that it is impossible to escape passing through an apprenticeship period of some sort. A university curriculum cannot possibly replace the apprenticeship period except in the cases of the comparatively small number of persons who are preparing for research and highly technical progress. Therefore, it is extremely important that the curriculum be such as will aid in choosing the proper kind of apprenticeship to fit the individual's mental endowment and his aptitudes. There should be fewer misfits because the first four years' training would give them an excellent foundation, and they could choose the type of work most interesting to them. This would eliminate a very real difficulty now in common existence. For instance, a boy before graduating from high school has built radio sets, worked in a local power plant, or had some kind of electrical experience. Perhaps electricity appeals to him more strongly than any other subject. He wants a university education because he has been told that it will enable him to earn a good salary immediately after graduation, and will go far toward insuring success in later life. What then is more natural than for him to register in electrical engineering, because here is the opportunity, in his opinion, to secure the university education he wishes and at the same time specialize in his favorite subject. Naturally he has considerable pride in his choice and is reluctant to make any change even though the first year or two may prove that he does not possess the necessary types of ability to succeed in engineering. He may eventually graduate and begin work, still determined to be a successful electrical engineer. The result is in many cases an employe who has not the ability and characteristics necessary for his work. He must then work on as best he can and be a failure or only a mediocre success in electrical engineering, or find something to which he is better adapted. In so far as possible, a young man's interests and abilities should be determined before he graduates. If this can be fairly well accomplished and he can be sent out either with the broad four-year training, or better, with both it and the two-year graduate study, his chances of success should be greatly improved, and he should be a happier man in later life.

R. W. Sorensen: I would like to add to the list of books given at the end of Professor Ryan's paper one entitled, "Ions Electrons, and Ionization Radiations" by J. H. Crowther, published by Edward Arnold, London. That book is easy to read and it presents in a reliable manner much of the information about ions that engineers wish to know.

In the three papers bearing directly upon education, you will, of course, find differences of opinion, and so there should be. The biggest crime educators could be guilty of would be that of making a standard curriculum, which would be the same for all engineering colleges. In fact, we often remind ourselves at California Institute of Technology that we must not simply add to the group of good engineering courses in California just another course like the one at our State University or like Professor Ryan has developed at Leland Stanford. We at the Institute are spending annually about $700 per year per student enrolled, to carry on our work. That money has been given us by individuals for a specific purpose and should not be used to duplicate the work of other institutions.

Dr. Magnusson has sounded a keynote when he says every faculty man should do enough research work to show that he has the ability to inspire students in that direction. Some undergraduates are qualified to do research work along with their regular undergraduate work. Such men should be given an opportunity to do that work. Also, there should be graduate students, the more the better, doing research work, and the college should make such provisions for such a plan. In this way, every student has a chance to come in contact with research work, learn what it is and methods of procedure. Every engineer will, to a large extent, have his success determined by the amount of research enthusiasm which he can develop, even though that enthusiasm is not applied to the type of problem ordinarily classified as a research problem.

As to the senior thesis for all, the discontinuance of that plan was due to several factors; one being lack of time on the part of faculty to supervise many students and assign each student a problem of just the proper magnitude to fulfill the requirements for graduation. In place of the thesis, certain problems are assigned students, the problems selected being tempered by the circumstances under which the student is working. Such a problem does not have to be written in thesis form, thus allowing all the available time for work on the problem.

Why do we include four years of English in our curriculum? We have had complaints that the engineers are underpaid, and underpaid chiefly for one reason; that the engineer confines most of his contact with men to those who talk only engineering language, and there is no use to try to sell engineering information to other engineers unless you are a much better engineer than the other man, which doesn't happen very often. On the other hand, there are thousands of people in the world who want engineering information and who would take it if presented to them so they could understand it. You can't present engineering data to the artist in a way that he will understand it unless you know his language; you can't present it to the doctor, lawyer, or merchant in a way that they can understand, unless you know something of their language.

Therefore, we have a department of English which runs through five years of our five-year course, and we must have a large department in order to keep the type of instructors we have, instructors whose business it is to inspire men and cause them to make of themselves all-round men. That is the reason we think it worth while to put in a five-year humanity course right along with a five-year technical course. Many of us would not do the things we do if some seemingly insignificant thing had not inspired us to go in an inviting direction. Without the instruction we would have failed in finding the doorway to new and interesting fields of endeavor.

In reply to the comments made by Messrs. Robinson, Clark, Henline and others, there are many details about which we could argue, but each exception only makes plainer the fact that all individuals should not be required to follow the same course of preparation for engineering work. Some men should prepare a thesis, some should not, some should have five years of education in the field of English literature, including some history and economics, others should find it more profitable to plan a different use of their time, but in nearly every case, I would conclude that in the essential things there are no differences of opinion—except as to relative values. This condition could not be otherwise because engineers differ as to details even in designing machines, when a much smaller number of variables are encountered than is the case when we attempt to form the character of the youth who will in the future be our engineers.

Reference to values in character building prompts me to direct attention to the value of the training obtained on the athletic field as evidenced by the success of many of our engineering students who participate in athletics. A survey of the condition

governing athletics at many of our educational institutions indicates to me that the advantages of athletics are for the most part lost to engineers because training for athletics has become such a time-absorbing specialty as to make it almost impossible for an engineering student to be on his college team. Our educators in the technical field, and those who are our friends, should help correct this condition of affairs.

C. E. Magnusson: Mr. Robinson's remarks lead me to think that I failed to state clearly what I had in mind. I meant to say that education is essentially training to think; that engineering education is training to think along engineering lines; that the main purpose of engineering students during their four years in college should be to gain clear concepts of the basic physical laws underlying engineering and acquire the ability to apply these laws to the solution of quantitative practical problems. The rest of their college work is accessory to this backbone of engineering education and may vary widely for different individuals. It goes without saying that all live engineering colleges frequently revise their curricula. At the University of Washington, the revision of curricula in the college of engineering comes regularly on the calendar every four years, and many changes both in regard to required courses and their content have been made during the past twenty years. I am grateful to Mr. Clark for emphasizing the value to industrial establishments of research in our engineering colleges although this phase of the problem does not come under the title of my paper.

FUNDAMENTAL CONSIDERATIONS OF POWER LIMITS OF TRANSMISSION SYSTEMS[1]

(Doherty and Dewey)

AND

ANALYTICAL DISCUSSION OF SOME FACTORS ENTERING INTO THE PROBLEM OF TRANSMISSION STABILITY[2]

(Fortescue)

Seattle, Washington, September 16, 1925

P. H. Thomas: The paper by Doherty and Dewey emphasizes even more than those of previous date the part played by the terminal apparatus in stability of operation. Of course, it matters not what the electrical equations show as to the theoretical capacity of a long line if when terminal apparatus be applied to supply power and receive load the combination is unstable to operate, as might easily be the case with loads anywhere nearly approaching the theoretical capacity of the line should the usual present designs of synchronous apparatus be used.

However, we have this fact to remember; the capacity of the line as shown by equations is an absolute limit without power of change until some of the physical constants of the line are changed, while the limitations of the terminal apparatus are merely matters of economy and cost. The very long transmission line may well represent $125 per kilowatt of delivered power, while the terminal apparatus costs much less; at least so far as the securing of suitable stability characteristics is concerned. If the choice lies between limiting the maximum duty of the long line and adding to the terminal-apparatus cost, the latter course is to be chosen, generally speaking.

The proposal to correct by simultaneous and automatic support of the field magnetizing turns the falling field strength when a line is suddenly overloaded, is a significant and important proposal and the analysis offered is clear and to the point. No doubt there are other ways of accomplishing this same result.

The 28 per cent greater load carried by the rectifier-excitation test as reported over the regulator test in the experimental line, is very encouraging. At the critical point of the regulator test it is evident that a further increase in power transmitted would require a higher actual field magnetism both on account of the higher load and on account of the less favorable power factor that the line will demand and temporarily also greater on account of the initial drop in terminal voltage. It should be noted that the motor end must drop behind on the increased load before anything at all happens in the electrical circuit. But this regulator cannot act until the voltage actually has dropped and by that time the system has dropped out of step and the regulator never gets a chance to try. With the rectifier, however, an excess of exciting power is added in the field before the motor drops back to the new position for the greater load and the field is ready to support the necessary additional power current.

I think the authors are a little too severe in their reflections on the line charging current. While it may be true that with certain set-ups due to the limitations in machines, the total theoretical maximum power which can be delivered by the line will be slightly less over the line having its normal electrostatic capacity than over a hypothetical line with no capacity, nevertheless it is not likely that charging current will be a detriment under practical operating conditions.

The statement that a certain 300,000-kv-a. station may deliver more power over two lines than over three and none at all over nine lines is not so significant as it might seem. It simply means that, for the three or nine lines, the system is so proportioned that machine capacity which should be devoted to carrying kilowatts is absorbed in carrying charging current or that the ratio of synchronous condensers to number of lines is not favorable. Either the kv-a. of the station should be increased by building the machines to operate at a lower power factor or shunt reactance or other means used to neutralize a part of the charging current. It goes without saying that it would not be economical to use an unnecessary number of lines.

With regard to the authors' Fig. 3 and the discussion of the part played by field current, I should like to point out that, with a heavily loaded line, there is very little choice as to power factor, for this is definitely fixed by the load and the terminal voltages and will inevitably be high at the generator end. However, there is this advantage of power factor near unity; the effect of added lagging current due to increase of load on the drop from internal impedance within the machine is small with high power factor. This is an important matter.

Since the power factor changes with every change in load on the long line, the curves of Fig. 3 should be supplemented by other curves showing the effect of such change of power factor, and these modified curves might easily show a different best relation between low-power-factor and high-power-factor loading, from that indicated by the uncorrected curves.

One other point; the authors state that the scheme of using divided line conductors to reduce reactance and increase capacity has not found favor partly because of the increased charging current. As I see it, this increased charging current is, on the whole, no disadvantage, for on any useful loading it greatly improves the line power factor. While it is true that leading current will tend to reduce the field-current setting in generators, this is a matter affecting only the performance of the generator, subject to correction in a number of ways. If the rectifier excitation scheme proposed in the paper or any equivalent scheme is available, this objection to the high charging current disappears. Meanwhile the reduction of line reactance which accompanies the increase in capacity with divided conductors, means an increase of substantially the same proportion in the maximum load the line will carry, assuming the percentage of line resistance loss to be kept constant. With a 20 per cent increase in line capacity in a 350-mi. line and with a favorable line power factor, any generator difficulties from the additional charging current would no doubt be cared for in the same suitable way. As a matter of fact on any full loading no charging current would appear at the terminals as the reactance energy of the line would absorb it.

F. L. Lawton: In the paper by Messrs. Doherty and Dewey, considerable emphasis has been given the question of voltage regulation of the synchronous equipment of transmission systems. This, however, is in line with the papers[3] and discussions[4] at the last Midwinter Convention when the subject of high-speed excitation was given prominence.

As the method of regulation outlined by Messrs. Doherty and Dewey—viz., the use of mercury-arc rectifiers as adjuncts in the excitation circuits of transmission-system synchronous equipment—is probably the most promising development looking toward increased system stability, it seems wise to discuss it somewhat in detail.

During the course of various investigations of the stability of power-transmission systems, it was realized that considerably greater stiffness in a system would be desirable; also, that such greater stiffness could be secured by the use of excitation systems having a time constant much smaller than usual. As a consequence, Messrs. Fortescue and Wagner discussed results they had obtained with a so-called high-speed exciter, at the 1925 Midwinter Convention.[5]

While it is true that less voltage fluctuation will occur during load or short-circuit transients, when the synchronous machines of a power system are excited by high-speed exciters, it must be remembered that such exciters are inherently not different from any other exciter, so far as behavior under transient conditions is concerned. That is, when lagging load is suddenly added to a generator so equipped, the terminal voltage drops. The decrease in voltage energizes the Tirrill-regulator relay which short circuits the exciter field resistance, permitting the generator field current to increase.

After an appreciable time, the alternator terminal voltage is restored to the normal value. *Inasmuch as the alternator armature reaction is not compensated for at the time it occurs, the power limit,* for slowly applied loads, of any system equipped with high-speed excitation equipment, *is no greater* than for a system provided with normal exciters. Furthermore, as it is now realized that a power-transmission system is inherently stable for any load up to the steady-state power limit, no matter how added, there is of comparatively little advantage in the use of such high-speed exciters beyond the reduction of voltage fluctuations.

Let us consider the case of an alternator equipped with an ordinary excitation system with the addition of a mercury-arc rectifier, excited from the line, as an adjunct. When a lagging load is thrown on such an alternator, the rectifier supplies an excitation current proportionate to the line current, varying simultaneously with it. *As a result of the simultaneity of action, the alternator armature reaction is at all times counterbalanced by a proportionate field current.* That is, *the armature reaction is effectively neutralized.*

As Messrs. Doherty and Dewey have indicated, a reduction of about 50 per cent in effective armature reaction was obtained. While this reduction was not so great as theoretically possible, nevertheless it resulted in an increase of 28 per cent in the steady-state power limit of a 250-mi. miniature system.

It is worthy of note that this gain was maintained during tests involving the sudden addition of loads when if ever, it might be expected that the rectifiers would be ineffective. Not only were increased power limits obtained, but practically no decrease in voltage occurred when a large load was suddenly added to a system equipped with mercury-arc rectifiers; but as much as a 20 per cent momentary drop in voltage occurred when the same load was added in the same way to the system using normal Tirrill-controlled excitation systems.

The advantages of rectifiers as adjuncts in the excitation circuits of transmission-system synchronous equipment are probably most marked in the case of system short circuits. Tests similar in all respects except the excitation circuits, have been made on the systems illustrated by the accompanying Fig. 1 to determine the maximum amount of power which could be transmitted with stable operation under the condition of a half-second, single-phase, dead, line-to-line short circuit at the mid-point. It has been found that the system with rectifiers

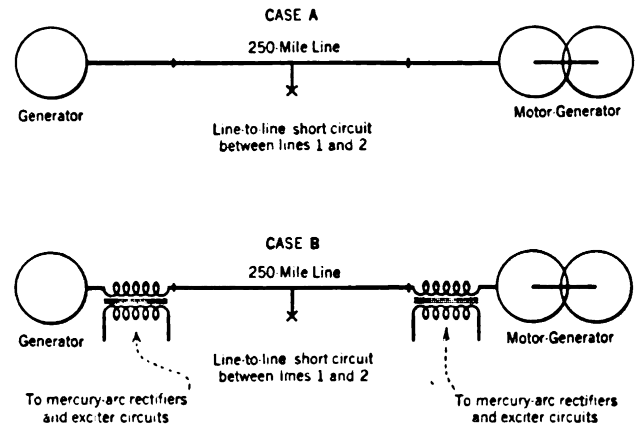

FIG. 1—SCHEMATIC DIAGRAM OF SYSTEMS USED FOR SHORT CIRCUIT TESTS

could carry 50 per cent greater load with much less fluctuation in voltage. To illustrate the comparative voltage fluctuations, Fig. 2 herewith has been prepared. Case A, Fig. 2, shows the three receiving-end voltages for the system of Case A, Fig. 1, while Case B gives the corresponding voltages for the other system. While the duration of short circuit for Case B was somewhat less than for Case A, the load being carried prior to the short circuit was 35 per cent greater and the initial short-circuit current 50 per cent greater. In spite of these unfavorable factors, the decrease in voltage was less with the system of Case B; virtually no over-voltage occurred when the short circuit was cleared. With the system of Case A, considerable excess voltage occurred some time after the clearance of the short circuit; a much greater time was required for the restoration of normal voltage.

FIG. 2—VOLTAGE DISTURBANCE DURING A SINGLE-PHASE, LINE-TO-LINE SHORT CIRCUIT ON A 220-MILE SYSTEM

The above facts illustrate the very important advantages which may be gained by the successful application of mercury-arc rectifiers in the excitation circuits of the generators and other large synchronous equipment of power-transmission systems. There appear to be no disadvantages beyond the possible necessity for oil circuit breakers of a somewhat higher rating, at a few points.

3. Power System Transients. V. Bush & R. D. Booth, A. I. E. E. JOURNAL, March 1925, p. 229.
4. Discussion. A. I. E. E. JOURNAL, July, 1925, pp. 766-771.
5. A. I. E. E. JOURNAL, pp. 767-770.

In conclusion, it appears that the only high-speed excitation system which will enable the securing of increased system power limits, for all conditions of operation, must be such that the armature reaction of the synchronous machines is effectively neutralized by the addition of field ampere-turns in the proper space-phase simultaneously with the occurrence of the armature reaction.

I believe the mercury-arc rectifier, properly applied as an auxiliary in the excitation circuits of synchronous units, is the first development giving promise of *a real increase in the power-transmitting capacity of transmission systems.*

S. B. Griscom: The statement by Messrs. Doherty and Dewey that, during transients, "the synchronous apparatus becomes inherently more powerful" is not clear. The field transient accompanying an increase in armature current is of such a nature as to tend to prevent the main field flux from decreasing, but it does not strengthen it. Actually, the magnetic flux starts to decrease immediately upon an increase in armature current; and consequently the field becomes weaker. Another way of stating it is that the very presence of the additional field current, flowing through the field resistance, is *due* to a decreasing field flux.

Under "Regulation," it is stated that the slope $\frac{dE}{dP}$ of the voltage-power curve determines the degree of stability. I should like to point out that such a criterion does not take into consideration the mechanical transients which are always coincident with an unstable condition, and it may, therefore, lead to erroneous conclusions. In the region where $\frac{dE}{dP}$ approaches infinity, $\frac{dP}{dt}$ approaches zero, because $\frac{dP}{d\theta}$ is limited by the mass of the synchronous machines. For this reason $\frac{dE}{dt}$ becomes very small and, in the case of large systems having heavy masses, is undoubtedly much less than the combined time constants of voltage regulators, exciters and generator fields, for a normal building up of load. The maximum load which may be carried under steady conditions is therefore considerably increased by the use of voltage regulators. This conclusion agrees in a general way with similar conclusions by the authors although in some cases apparently contradictory statements and data are introduced.

In particular, it would be expected that the tests reported at the bottom of the eleventh page should show nearly equal maximum loads for the two forms of excitation used, provided the load was built up by increments that were small as compared with the stored energy released during a small shift in phase of the synchronous motor. It is also probable that a load consisting of a large number of small synchronous units would cause the power transmitted over the line to change more slowly, giving more time for the regulator to function.

In a similar manner, voltage regulators on synchronous condensers located at intermediate points on a transmission line, by holding the voltage constant under a gradually increasing load, should permit a much greater power to be transmitted than the same line with the same total condenser capacity located at the receiver end only. The maximum power limit of such a system, as given by the authors appears to be entirely too low for a condition of steady loading. During transients, the maximum load that can be transmitted safely is considerably reduced but will still be much higher than a straight-away line for the same disturbance.

The use of synchronous condensers at intermediate points has been discussed a number of times, but the advantages apparently have not been fully appreciated. Condensers are usually installed for the purpose of voltage regulation and since the receiving end of the line is usually the only point where voltage regulation is needed, all of the condensers are located there. However, the real function of the condensers is to supply the reactive energy loss due to the flow of current through the line reactance. This loss is distributed practically uniformly over the length of the line and consequently a reduction in copper loss and a slight decrease in total condenser capacity may be effected by installing a portion of the condenser capacity at an intermediate point. Such an arrangement would tend to reduce short-circuit currents, particularly at the receiving end which is usually a point of high power concentration. Location of condensers at intermediate points should not prove unduly expensive or difficult because, in the majority of cases, switching stations and attendance will be required for line sectionalizing. Machines of suitable characteristics and equipped with a high-speed excitation system, or compensation, are of particular advantage for this application. It should be noted, however, that such features are made desirable principally by the conditions obtaining during transients and not for steady loading.

R. D. Evans: Probably the most interesting data submitted by Doherty and Dewey are the results of the calculations shown in Fig. 2 of their paper. This figure shows the "Maximum power which can be transmitted 250 mi. at 220,000 volts, shown as a function of the capacity of synchronous apparatus, and the number of transmission circuits."

The curves of Fig. 2 were presented for the purpose of showing the importance of the charging kv-a. of lines in reducing the power limit and they serve this purpose in an excellent manner. However, the important effects of the charging kv-a. in limiting the maximum power appear only when the synchronous capacity is small in comparison with charging kv-a. of the transmission line. This condition of operation would suggest that a lower transmission voltage would give higher actual power limits.

The condition in which the generating capacity is small per line is of relatively minor importance because the power to be transmitted per circuit at 220 kv., 250 mi., must be of the order of 75,000 to 125,000 kw. in order to be within the economical range at the present time. With this relation in mind, it is advantageous to compare the results shown in Fig. 2 for different kv-a. capacities of synchronous apparatus. In the first place, it will be noted that the characteristics of machines assumed by Doherty and Dewey are such that the rating of the machine cannot be developed because the power limit of the system is approximately two-thirds of the nominal capacity of the synchronous machines, that is, 100,000-kv-a. capacity on this line will show a power limit of approximately 70,000 kw. per circuit. If the characteristics of the terminal equipment are altered so that the reactance is approximately two-thirds, and the field current approximately three-halves of the values assumed, the power limit would be increased to approximately 100,000 kw. This condition would correspond to the curve given in the paper for 150,000 kv-a. in synchronous apparatus. Similarly, if a power limit of 150,000 kw. were to be obtained, the machines should have approximately somewhat less than two-thirds the reactance and more than three-halves of the excitation of the machines assumed by Doherty and Dewey. In other words, the power limit per circuit can be increased up to at least 125,000 kw. per circuit by the use of machines of suitable characteristics. The significance of this discussion is that the desired static limit may be obtained by merely modifying the authors' assumptions so as to employ machines of lower reactance and higher excitation. In the absence of alternatives, which are still in the development stages such as special regulator and compensator schemes, the use of machines of suitable characteristics is a practical solution available at the present time for producing quite marked increases in the stability of systems.

In view of the position taken by the authors, that static

limits are the only limits that are worthy of computation, it is interesting to compare the calculated static stability limits as given in Fig. 2 of the paper with the practical results of experience on an actual 220-kv. system. For a single-circuit, 250-mi. transmission system operated at 60 cycles, with approximately 200,000 kv-a. in synchronous apparatus at each end, the static limit is calculated to be about 115,000 kw. In the June issue of the *Electric Journal*, H. A. Barre states that the static limit of the Edison System was reached under a particular emergency condition. For this condition, power was transmitted from 240 to 270 mi. over a single circuit at 220 kv., 50 cycles, with approximately 200,000 kv-a. in synchronous apparatus at each end, and the static limit was found under actual operating conditions to be 183,000 kw. One would expect that the static condition on the Edison system would correspond well with the other condition mentioned previously, the greater length of the 50-cycle system and the probably greater transformer impedance roughly compensating for the increased frequency upon which the calculations were based if the authors had assumed machine characteristics corresponding to those of the synchronous apparatus on the Big Creek system. What is the explanation of this discrepancy from 183,000 kw. on an actual system to 115,000 kw. as given in the calculated results? In the first place, the exact assumptions used by Doherty and Dewey are not stated, and it may be that the explanation lies in them. If such is the case, the Fig. 2 should be interpreted with care. A possible explanation may lie in the fact that probably synchronous motor load was assumed in the Doherty and Dewey calculations, whereas the actual system involves a certain amount of resistance load which would cause the power to fall off with drop in voltage. The influence of the load characteristics is not mentioned, so far as the writer can recall, at any point in the paper, and it may be that this factor is of importance in the particular case of the static limit on the Edison system and under certain conditions would undoubtedly be of great importance in other cases. The explanation of the discrepancy between the calculated maximum limit and the maximum limit obtained under actual operating conditions is, of course, very important. It is worth pointing out that actual static limits may be appreciably in excess of calculated limits which do not take into account all the factors affecting stability.

S. W. Copley: These two papers indicate that the methods of calculation used do not differ greatly fundamentally, but there is some difference between them in the assumptions made as to the values used for the characteristics of the terminal apparatus. This difference causes some important divergence in views as to the power-limit figures. Possibly Doherty and Dewey are too pessimistic in their assumptions with respect to the reactance of terminal apparatus, or they have not given enough credit to the action of voltage regulators in holding the system together. Both of these points warrant further investigation. Machines of lower reactance can be designed and a regulator which has higher speed characteristics is a possibility. There are certain drawbacks to the application of such machines and regulators, but if the limits of power transmission must be raised the disadvantages can without doubt be overcome.

C. L. Fortescue: Messrs. Doherty and Dewey have presented with clarity the characteristics of synchronous apparatus which are of importance in the problem of stability. In dealing with the stability of machines of this type, they have laid much stress on the fact that high power factor is detrimental to stability, as it involves low excitation or, what is the same thing, low internal voltage. While undoubtedly at times, transmission lines reach very low loads in which the excitation is correspondingly low, I do not know of a single case in which a system was thrown out of step by a sudden increase of load or a short circuit due to low excitation. I believe that the explanation which I shall give later will account for the fact that instability under such conditions is practically unknown.

While I believe we should keep such cases in mind as elements of the problem, I feel that the authors have over-emphasized their importance and may, therefore, produce a false impression in the minds of those who are not sufficiently familiar with the problem. A properly designed transmission system will make provision for the generators not to supply all of the charging current at light load, and, at heavy loads, the generator power factor will be normally lagging. Two transmission lines properly designed with the proper size of generating station and with proper provision at the receiver end and intermediate points to take care of the line reactive-volt-ampere requirements will always transmit more power than one line. I state this fact not because I believe the authors intended to convey the opposite impression but the emphasis they lay on certain features of generators and synchronous motors might easily convey the opposite idea to the minds of those who are not closely in touch with the problem.

I had felt encouraged when I read the statement made by the authors on the fourth page, column one, and in the first part of column two as to the importance of excitation, though I will take issue with them in regard to part of the statement by referring to a discussion on excitation in last Midwinter Convention by several of my colleagues in which the possibilities of high-speed excitation were discussed at some length and with considerable emphasis. Later on in their paper I was disappointed to find that the authors had reached the conclusion that high-speed excitation would not fit the bill but inherent regulation was what would be required. Again I must take issue with them in this matter and state that in my opinion they have reached an erroneous conclusion and their error is mainly due to their failure to perceive that the so-called static-stability problem is in reality one of transient stability.

I shall first show by means of a simple mechanical model that if generator and motor are provided with perfect regulators, no matter what their characteristics, they will furnish power up to the stability limit of the line itself. The model which I have in mind is quite simple and was devised by S. B. Griscom. If two sticks pivoted about one point are connected at the two ends by an extensible elastic string such that its linear extension is proportionate to its tension, and if torque be applied to one member the restraining torque on the other member will represent the power output of a line. The applied torque is the power input. The above applied to a line having no losses but having reactance and distributed capacity. This assumption involves no appreciable error in considering the actions that cause instability because the resistance of the line and generators has only a small effect on the stability problem.

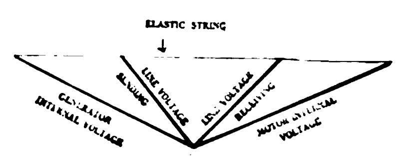

FIG. 3

One may picture one of these pivoted members attached rigidly to the shaft of a motor and the other to the shaft of a generator. The motor drives the generator at constant speed, using this device as a mechanical transmission. As the generator load increases, the elastic connection would be extended in such a way that the sine of the angle between the two members will increase in proportion to the load. If we keep on loading the generator, the angle between the two members will finally become a right angle, at which point the mechanical transmission system will have reached its maximum ability to transmit power and the system will become unstable.

Now the internal voltages of the generator and motor may be represented by two additional sticks (as shown in the accompany-

ing illustration) as extensions of the transmission line beyond this angle. The terminal voltages are kept constant; that is to say, the length of the original two pivoted sticks. As the angle is increased, the elastic line is kept straight by increasing the sticks representing the generator and motor internal voltages. Using this model, it can be shown that the torque at the generator will reach its maximum when the two members representing the terminal voltage of the transmission line are at an angle of 90 deg. with each other.

I have made no restrictions as to the characteristics of the generators and motors except in the matter of losses as in the case of the transmission line, but it is easy to show by means of the model that the rate at which the internal voltage must be increased with increase of load is very much influenced by the internal characteristics of the machines, and if we make the internal leakage impedance low, we shall not require to have as great a range of excitation.

Objection may be raised that ideal excitation systems do not exist and that commercial regulators are too slow. The explanation resides in the fact that the problem is, in reality, not one of static stability but one of transient stability. You must remember that instability involves a change in angular position and this means a change in angular position of the generator rotor and the motor rotor as well as of the line terminal voltage. The electrical angle and mechanical angle are, you might say, irrevocably tied together and to deliver power to a motor through a line at a given excitation requires that they must take up a definite angular position with reference to each other. In my paper, I have pointed out that the angular relation is a continuous function of the power and is therefore suitable for analytical work whereas the voltage at the terminals is a discontinuous function and is not suitable for analytical work.

The fact that the angular positions of the rotors must change with change of load introduces the natural period of the system into the problem of voltage regulation and this means also that sluggishness of the hydraulic or steam governor may have some advantages. If the load is increased, the motor slows down and so does the generator. In slowing down, the motor supplies part of the increased load by inertia. The generator supplies part of the increase in transmitted load by inertia at a slightly lower frequency, so that matters are improved from a stability point of view since, during this stage, only part of the increased load must be transmitted and also because it is transmitted at an appreciably lower frequency. While this is going on, the regulator has had time to get in its work and if the angular change is not too great, the voltage regulator will catch up before the angular displacement has reached the point where the system will pull apart at the increased value of load. Theoretically, this may be carried out close to the limit of stability of the line, providing the load increments are not so great as to cause large swings.

The authors have made no mention of the effect of the characteristics of the load and have merely touched on the improvement to be obtained by changing the generator characteristics, dismissing it with a statement that it will prove too costly. I wish to take exception to this statement and to say that such changes can be made with a small increase in cost over that of standard generators and the increase in the ability of the system to transmit power will more than counterbalance this added cost. Such generators are immediately available and, with specially designed high-speed exciters, will permit of operation of transmission lines with a high stability limit.

In regard to the problems of internally compensated machines, much progress has been made along these lines, but since it is still in the development stage, very little can be said about it at present. It is possible to compensate a generator completely and even to extend this compensation to cover the impedance of transformers so that the generator has the characteristics of the infinite system of which Mr. Doherty and Mr. Dewey speak in their paper; but there are grave questions to be considered in the application of such machines. The rapid retardation and acceleration, caused by short circuits, and the subsequent clearing of the lines may produce mechanical stresses of great magnitude. In all probability some limiting device will be needed to limit the amount of current that can be delivered above a certain value.

Regarding the matter of transients due to short circuits, I agree with the authors that experience has shown that in existing systems with suitable relay protection, short circuits do not constitute a serious problem in operation. However, they make the statement that experience is the best guide and that calculations are always made on the basis of conservative premises and are therefore too pessimistic. The transient condition under short circuit will undoubtedly be the factor which will determine the ultimate rating of a transmission line and it behooves us to avoid being so conservative that our results are pessimistic.

I believe that we can or will be able to compute, with a fair degree of approximation, the results of a short circuit either to ground or between phases if we are provided with proper data as to ground resistance and load characteristics. I am further willing to go on record that we shall be able to install apparatus that will enable us to approach within a reasonable distance of the effect of an infinite system, not only on a straight-away transmission but also for one using intermediate synchronous condensers so that, with the latter system, the stability will be determined by the weakest section.

The automatic voltage regulator is not a hopeless problem for it is assisted by the fact that it takes time for the system to change its angular position whereas the terminal voltage changes instantly. Moreover, the internal reactions are resisted by inherent flow of exciting current. Therefore, the voltage regulator has time to act before the system gets beyond control.

P. H. Thomas: Mr. Fortescue, with his usual skill, has developed generalized equations for showing the theoretical limits of stability in electric systems containing synchronous machines.

The most difficult and illusive part of the problem of stability is the determination of the numerical value of the parameters of stability in particular cases and especially for the pendulum action or the tendency to overswing when a change of load in a system or its equivalent requires a new position of equilibrium. The principles involved are well understood and at least one analytical and one electric analog method have been proposed. These, however, are merely methods of overcoming the mathematical difficulties of the solution and still leave untouched the difficulty of properly evaluating the factors of losses and damper currents.

As is well known, any damper current set up by an advance or retreat in the position of the rotor with regard to the revolving field of the stator will tend to reduce, temporarily, the forces driving the rotor toward its new position of equilibrium and similarly, if the rotor over-shoots, these damper currents tend to restrain the over-swing. If sufficiently powerful, these forces may render the swing of the rotor dead-beat. The conditions governing the effect of these damper currents, which will usually be of very low frequency, should be fully studied to see what can be done therewith to restrain the overswing.

These damper currents should be controlled by the resistance of the damper rather than its reactance, but subject to this limitation the damper resistance should apparently be as low as possible. The field winding, having by far the greatest weight of copper surrounding the field poles would naturally have the most effective damper action.

While Mr. Fortescue has given a definition of stability which is entirely logical, we shall ultimately need something further; viz: a standard test or criterion to be satisfied by any particular system to insure reasonable continuity of operation.

It is yet too soon to offer such a criterion for actual adoption, but ultimately something in the nature of an overload to be taken at a certain power factor, or a drop of voltage (taking account of both ends of the line) that must be sustained without falling out of step, will be required.

It is gratifying that much has been done to render the terminal apparatus more responsive to its duties—but still more is desirable and no doubt possible, on account of the dominating importance of the cost of the line as compared with the cost of regulating and exciting means.

R. E. Doherty: I agree with the general point of view expressed by Mr. Fortescue—namely, that the lack of any great amount of trouble from instability up to the present time should not be interpreted as evidence that such a thing is not possible with longer lines and greater power; that, in any study of the problem, all elements of the system, including generators, exciters, condensers, lines, etc., and not merely one element of it, should be considered; that the problem involves two fundamentally different "states" of operation—"transient" and "steady"—during which the operating characteristics of the apparatus are different. I also agree with the general exposition regarding the angle-power relations, only in so far as it gives a physical, qualitative picture of the phenomenon. I strongly endorse his appeal for reliable information regarding ground resistance and would add an appeal for recorded data and system experience during single-phase short circuits. And, finally, I endorse the view that the mathematical, or even graphical, determination of stability of such system networks as comprise our modern power systems, is quite beyond the range of practical possibility. For these cases an equivalent system from which the required values can be obtained by test becomes necessary—just as for the same reason, it is necessary to thus determine short-circuit currents in complicated networks.

Such methods are available; the equivalent system proposed by C. A. Nickle[6] affords a valuable means of studying the power oscillations during transients, and the scheme proposed by Spencer and Hazen[7] affords a means of testing steady state power limits with practical accuracy. The latter method assumes sine-wave relation between power and angle, and is, therefore, roughly correct for maximum power studies. Nickle's method, however, in its present state of development, assumes linear relation between power and angle, and is, therefore, limited in this particular application to a study of the behavior of the various components of the system during those transients which do not involve power swings beyond the point where the linear relation ceases to hold. However, there are many interesting and important phenomena bearing on stability which can thus be determined; and if a circuit element giving the sine-wave relation is found, the maximum power can also be determined. The company with which I am associated is now completing the development of both of these facilities. While, of course, further improvements are ahead, the present development provides a very helpful aid, and, in my opinion, is a significant step forward.

There are a few points in the paper with which, if I interpret them correctly, I do not agree. They are relatively unimportant with respect to the general problem to which I have referred above, but have importance only in numerical calculations. I refer to the author's statement that the steady-state limit depends upon the leakage impedance and not upon the synchronous impedance. Making due allowance for saturation, which, in effect, reduces the impedance, the steady-state, ultimate power limit at normal voltage is determined by synchronous impedance, not by the leakage or "transient" impedance. A steady-state, hand-controlled test, giving a family of voltage-power curves, (as in Fig. 3 of the paper by Mr. Dewey and myself), shows the same power maxima as determined by automatic regulator tests, and as calculated, using synchronous reactance. While it is possible with an automatic regulator, as it is not by hand control, to throw on suddenly loads equal to the ultimate maximum steady-state power, it is nevertheless not possible, according to our tests and conception of the problem to carry significantly more than that by using a regulator actuated by the alternator terminal voltage and operating on a shunt- or compound-wound exciter of quick response. This is discussed fully in our paper.

In discussing the group of papers by Mr. Fortescue and his colleagues at the Midwinter Convention in 1924, I stated power limits which "in the present state of engineering knowledge" I considered to be justified. I said: "We must neither gamble that a voltage regulator will be able to insert a supporting prop under an otherwise falling system, nor depend for stability during load transients upon possible momentary favorable conditions due to momentary and field transients." Now the intensive study and investigation of the past year and a half has shown what we did not then know—that, up to the ultimate maximum power value, as determined by tests under hand control, the regulator can be depended upon to insert "the supporting prop," but not beyond that limit. I understand the author's statement to be that the regulator makes it possible to carry a constant load significantly greater than the above maximum; with this I disagree.

I do agree with the author that the object sought with an excitation system is to obtain the same characteristics as would be afforded by a machine which would inherently maintain constant flux linkages—one in which the field and damper resistances were zero. To say the same result would be obtained by an exciter of quick response which holds the alternator field approximately constant is in all respects parallel to the statement that if the terminal voltages at both ends of a line were held approximately constant by a regulator (as they can be, even by hand control, with gradual increases of load) the ultimate maximum power would be that of the line alone, *i. e.*, all limitations in the generator would thus be compensated, which obviously is not true. Yet the two cases essentially involve the same elements. It can be shown[8] that, following a load change, the flux change of the alternator field, $\frac{d\phi}{d\,t}$, is not zero, but essentially negative, unless a series negative resistance is introduced in the alternator field circuit. A method for obtaining this is described in our paper. A shunt- or compound-wound exciter, of however quick response, does not have this characteristic. Fortunately, however, for any load up to the ultimate steady-state limit at normal voltage, the ordinary exciter and regulator usually suffice; and this steady-state limit cannot, so far as our study and tests show, be increased by speeding up the exciter magnetically.

R. J. C. Wood: The main reaction I get from these papers is a feeling that perhaps we are using the wrong term when we talk about instability. We are not, ourselves, putting up the money to build these big systems, and I think that anything which suggests unduly, a weak point in transmission should be avoided. I do not mean by that we are to conceal the truth in any way, but there is a psychological effect produced by the word "instability," which I do not think is produced when we talk about power limit.

What we are getting at is the power limit of a system. There are various things which limit that power; the current may be so great that the wire will fuse and fall in half, or it may be this "instability" that we are talking about.

If you go out to buy an automobile you take the automobile out and try it and you run it up a hill and the hill is of increasing steepness. After a time that car just lies down and quits.

6. Oscillograph solution of Electro-Mechanical Systems, by C. A. Nickle, JOUR. A. I. E. E., p. 1277, Dec. 1925.

7. The Artificial Representation of Power Systems, H. H. Spencer and H. L. Hazen, A. I. E. E. JOURNAL, January, 1925, page 24.

8. Exciter Instability, R. E. Doherty, A. I. E. E. TRANSACTIONS, 1922, page 767, eq. 30.

You have not an unstable automobile; you simply have reached the limit of its ability. Perhaps you kill the engine; perhaps you spin the hind wheels. That might be an illustration of the generators falling out of step.

It would be better if we could think and speak of this more in terms of power limit; everybody is familiar with the idea of a limit of endurance, both humanly speaking and as regards apparatus and machinery.

Roy Wilkins: I am employed by a company owning an interconnected system of upwards 8000 mi. of line 60-kv. and over, and with a total generating capacity of a little over 880,000 kv.-a. The connecting rotating load is about 2,000,000 h. p. At different times there have been tested 110-kv. lines up to 500 mi. in length in operation and carrying load, and loops as long as 350 mi.

I should like to point out certain road signs in the line of "don'ts" for people who, in the actual power industry, take up the study of power limits or instability as it has been called. First, don't worry about anything except the actual operating conditions. You will find trouble enough without running into any weird combinations which are impossible operating conditions. Second, don't expect to simplify the problem and still check the performance of a complete transmission system, because in a transmission system, every piece of connected apparatus has certain characteristics. These characteristics are all in their proper places, proper order and proper values. Any simplification means a certain amount of error.

At the present time, there is too little known about circuit-breaker operations, corona, WR_2, impedance, load character and load power factor, together with certain cases of trouble as grounds, etc. As a passing note, nobody, at the present time, knows exactly what "load power factor" is. I haven't been able to measure it in a year and a half. The final result will come from a mass of accumulated operating data just as in the past for the final solution the twenty-year old problem of a grounded-neutral system came not from brilliant mathematics or special studies, but from the final check and the actual operating procedure of a great number of operating systems.

F. G. Baum: If you will read the TRANSACTIONS of the Institute of twenty years ago you will find that the problem of stability was then one of very great importance and a great deal of work was done on it at that time. The reason for its importance was this. The Stanley Company made for operation on the first long transmission systems, an inductor type of generator which had no revolving coils of any kind. The generator had 100 per cent reactance. It was good for the conditions which then existed, since we had only air switches with which to open the circuit. If there was a short circuit, the voltage dropped to zero and you could open the circuit with the air switches.

Generators were actually advertised as being capable of being short-circuited without damage and only a few years ago many engineers were specifying that the short-circuit current should not be over so many times normal current.

We are now talking transmission-line stability again, and the generators are the main element in it. The transmission line will take care of itself if you will take care of the generators. The reason we are talking so much about instability is because we have flashovers, or expect them, and therefore want to be ready to take up and quickly replace the difficulty caused by the flashover. In other words, the trouble now is with flashovers, while twenty-five years ago it was that we didn't have any switches. At the time the Stanley generator was put out I was in charge of the operation of the Pacific Gas and Electric Company in which we had a number of these generators and the regulation was very poor. The voltage variation under normal operations was so bad that we couldn't operate lights at the same time as motors. Something had to be done so we applied to all the synchronous apparatus an excitation in proportion to the load. All the d-c. load current was taken around the exciters and the voltages built on the d-c. exciter in proportion to the load.

At that time I also worked out a regulating scheme for the a-c. generators which would build up the generator voltage in proportion to the drop in voltage due to the load, which as you know is practically $I \sin \theta$. I wasn't popular for proposing that because the generators were being sold because they had poor regulation, and I proposed to make them good.

For the last year and a half we have been making quite elaborate tests on power limits of transmission systems, and I agree with Mr. Wood that it is power limits and not instability which we are talking about. We don't get instability unless we have troubles outside of those that are expected and most of those come from flashovers. Stop flashovers and you won't get the instability.

The tests made have checked calculations very, very accurately. Early last Spring we calculated the power limit on the Pit River System as 185,000 kw., using a power-angle diagram, which you will find in the *Electrical World* in 1902. The limit of the Edison system under actual operation has been found to be 183,000 kw. and if you will allow for the increased length of line and decreased frequency the results check.

I want to express surprise at the suggestion made in Doherty-Dewey paper for the use of series capacity in the transmission line. You can do that in a radio system but to consider it seriously for a transmission line seems unreasonable.

The most important part of the transmission system today is the oil switch and relays. If we didn't have them today we couldn't operate our transmission systems. Any electric power system of high or low voltage and without proper relays, switches and fuses to eliminate defective line sections is inoperative. I think you will agree with that, so I say, work on the oil switches and relays. First work on the flashovers, and get rid of those so the switches won't have any more to do than necessary. Then when you get through with that, static stability will be the criterion of your power line and not transient stability.

A statement has been made with reference to the limitations of long-distance power transmission, which was quoted in a morning paper. The statement was that with the present apparatus (and present state of mind, especially) 300-mi. transmission is questionable of economic results.

I challenge that statement. I think it should never have been made. Any man who sets a limit at the present time on power transmission either does not understand the problem or perhaps he is purposely making the statement for some other reason.

I wrote a paper for this meeting which I didn't submit because certain developments afterward made it advisable to add other information. The first sentence reads: "The natural and approximately the economic load per circuit for load transmission is given by the equation $P = 2.5\ E^2$."

If 220 kv. will not do the work, we can go to 330 kv., or some other reasonable voltage, and if 330 kv. won't do it, we can go to 440 kv. When I say that I am saying it in view of the intense study made in the last two years on insulation, coupled with the results obtained on the present system of the Pacific Gas & Electric Company, operated at 220,000 volts. It is the most successful piece of work we have undertaken, and the power is transmitted about 300 mi.

To have a real natural transmission system, you must balance the magnetic energy all along the line with the electrostatic energy. To develop that you get this equation, $I = E \sqrt{\frac{C}{L}}$. I want to call your attention to the importance of this equation. I think that equation is more important than Ohm's law or any other in electrical engineering. It is a

fundamental equation. Nature tries to transmit power with the conditions given by that equation.

Now, if I want more current, I can do three things; Raise the voltage, lower the reactance or increase capacity. Most people will recognize that if you lower the reactance you will immediately get increased line capacity, but they do not appear to recognize that if you increase C you get the same results practically. I can reduce L to one-half and multiply the amount of power by $\sqrt{2}$; I can change C by doubling its value and also increase the power by $\sqrt{2}$.

Regarding line insulation, with the study we have been making in the last year and a half, I am satisfied that when we want the 330 kv. we can get it. We started this work early in 1924, not because of any troubles on our present 220-kv. transmission lines, but because we didn't want to be caught like we were in 1912 when we put in the 110-kv. lines, and later found troubles we didn't know anything about. We decided in 1924 that we would make a thorough study of insulation. The Westinghouse Company has supported that work on insulation, and the Pacific Gas and Electric Company is cooperating in the long-line tests and the practical tests which we find necessary.

So the first thing was to decide how to get at the matter of the mechanism of flashovers. I decided, after several years of study, taking probably thousands of flashovers and arriving at no mental picture of what was happening, that we had to get a reliable picture of what actually was happening whenever we had a breakdown. To get that we decided that we should probably have to get at it from a d-c. standpoint, projecting the electrons through the air, and if possible taking their pictures on the way. They are fast-moving and don't pose very long.

The pictures we have taken will I believe give a mental picture of the insulation of the air such as we have not had and I believe the work done and being done will tell us the true story of line insulation.

R. E. Doherty: The extensive discussion indicates a keen interest in this important subject, and serves the very helpful purpose of focusing attention on those points which have not yet been generally agreed upon. The more they are discussed, the more they will be studied and the sooner will the various interested engineers agree upon the more important details. While perhaps there is not at this time *universal* agreement upon even the more fundamental aspects of the problem, there has been, I think, for the past two years general agreement on these fundamental aspects by those who have given the matter serious study. As I mentioned at the Midwinter Convention at Philadelphia, in 1924, the fundamental theory underlying the problem, and the equations arrived therefrom, are used by all informed engineers. Divergence of views enters only when assumptions are made regarding numerical values for a particular case. More specifically, disagreement centers, not about the transmission-line theory or the general equations of the system, but about faulty understanding regarding internal characteristics and constants of synchronous machines. Although different views regarding such machine characteristics apparently result in different estimates of maximum power which can be transmitted over a given system, I am not sure that this difference is as great as might be expected from the tone of the discussion. Messrs. Fortescue and Evans say that the calculated values in our paper are too low, but they do not indicate what these values should be. And I believe that in any definite proposed undertaking, their conclusions as to the practical feasibility of carrying out the given proposal, would not be significantly different from ours. Indeed, in more recent proposals where such parallel studies have been made, the conclusions have not been widely different. All of which indicates, of course, that the protracted discussion regarding certain alleged, weird behavior of synchronous machines is somewhat of a trifling character, and not of the importance which engineers not familiar with such details might be led to suspect.

I shall attempt to answer the questions raised regarding our paper, although most of them could have been answered by referring to statements in the paper. Mr. Thomas believes that it is not likely that the charging current of a long line will be a detriment under practical operating conditions. It may, indeed, be a great advantage provided the generating capacity at the end of the line is sufficiently large, as clearly shown in Fig. 2. But this is not a matter of opinion; the extent of its effect can be easily computed for any given case. It must not be concluded just because calculations made on the basis of constant terminal voltage show a larger power limit with the normal line capacitance than without it, that the same result would obtain with synchronous apparatus of a kv-a. capacity comparable with the load to be transmitted.

Mr. Griscom states that he does not understand why synchronous apparatus becomes inherently more powerful during transients. The reason is that, for the moment, the *transient* reactance, instead of the *synchronous* reactance, determines the power characteristic of the synchronous machines. The ratio of synchronous reactance to transient reactance in ordinary commercial synchronous machines is of the order of 5 to 1. It may be as low as 3 to 1, or as high as 10 to 1. In other words, in rough values the synchronous reactance is about 100 per cent, and the transient reactance about 20 per cent. Thus the machine in such a transient state is decisively stiffened up. Mr. Griscom's question would probably be removed by reading over the paper—under the heading "Transients."

He also questions whether the slope of the voltage-power curve determines the degree of stability. If the slope is zero at all values of power, it merely indicates that the voltage of the bus under consideration is not affected by any power change whatsoever, regardless of whether the synchronous machines constituting the infinite bus are of zero inertia or infinite inertia or any value between these extremes. Mr. Griscom's statement is correct that when $\frac{d\,E}{d\,P}$ approaches infinity, $\frac{d\,P}{d\,T}$ approaches O; but this is not, as Mr. Griscom states, because $\frac{d\,P}{d\,\Theta}$ is limited by the mass of the synchronous machines, but because at that moment the electrical characteristics are such that the power is not changing, although the angle Θ may be changing.

I wish to add a word about this 183,000-kw. story as related by both Mr. Evans and Mr. Baum, and which Mr. Dewey has answered. When the engineers of the country are eagerly waiting for every additional fact of operating experience bearing on this subject, it seems unfortunate, indeed, that when some real data do become available, their meaning should be so completely misunderstood or misinterpreted. When the sending end wattmeter reads 183,000 kw. and the receiving-end meter reads 135,000 kw., should we say or imply that 183,000 kw. is *transmitted over* the line? And I think that neither Mr. Evans nor Mr. Baum would, after serious thought, adduce that test (which our calculations check) as evidence that our calculated values are much too low. In Mr. Evans' published work, he calculates, as most every one does, the receiver-end, not the sending-end, power.

Mr. Evans raises two other points: One is that the maximum power can be increased by reducing the reactance of the generator; the other, that Fig. 2 might be misleading. As to the one, the authors heartily agree, as presumably every one else does. Nobody would question that. The question is *how* will you decrease the reactance. Mr. Evans is referred back to the paper to the heading "Design," where this matter is fully discussed. The generator capacities given are based on present-day practise—synchronous reactance approximately 100 per cent. Nothing

would be gained by cutting the ratings to, say, one-half, thus reducing the per cent reactance to 50 per cent. That would not increase the maximum power. The question is how would one alter the design of a machine of given magnetic dimensions in order to lower the synchronous reactance, and to what extent could it be thus lowered. There could not be much disagreement among informed designing engineers on that point. After that is done, any further reduction must be obtained by increasing the active volume of the machine, or by adding more machines. Thus, as Mr. Evans says, and as the paper clearly points out, "quite marked increases in the stability" can be obtained in these ways, but there are perfectly obvious reasons, as the paper also points out, why this process cannot be extended far enough to satisfactorily solve the problem.

The other point raised by Mr. Evans is well founded. The authors acknowledge that the title of Fig. 2 should be more specific, and will revise it accordingly. The illustration refers to a 250-mi. straight-away line with synchronous-motor load.

Mr. Fortescue does not know of "a single case in which a system was thrown out of step by a sudden increase in load, or short circuit due to low excitation." There have been such cases, nevertheless. The September 1919 trouble of the Commonwealth Edison Company, described by Dr. Steinmetz in the 1920 TRANSACTIONS, is one notable example among others.

The authors naturally agree that if an additional line with duplicate sending and receiving apparatus be installed, the maximum power will be increased. Two power *systems* will obviously carry more than one. But that is not the point. Fig. 2 merely shows the relation between generating capacity, number of lines and maximum power. To say, as Mr. Fortescue does, that two "properly designed" systems with "proper size generating stations," etc., etc., will always carry more than one, would hardly bear close scrutiny where costs are regarded; because "proper size" for maximum power may be prohibitive in cost.

It does not require a mechanical model to prove the platitude that if "the terminal voltages are kept constant," the power limit will be the limit of the line itself. But to the authors' knowledge the "perfect regulator" to hold this condition does not exist. When it shall exist, or else some other method than synchronous operation is utilized, it will be time enough to talk seriously about the limit of the line alone. I have discussed this problem of regulation in my comments on Mr. Fortescue's paper.

Mr. Fortescue also bespeaks the gain from changing the generator characteristics. Such changed generators, he avers, will permit of operation with a "high stability limit," but he doesn't say how high. And the whole point, if there is any, depends upon *how high*. He, like Mr. Evans, is referred to the paper under the heading "Design."

They also mention that the authors have not discussed the effect of load characteristics. Loads which are functions of the voltage, such as lights and certain classes of converters feeding a constant voltage d-c. bus, are inherently stable. These have a maximum power, but that is not the limit of stability. Indeed, there is no stability limit with a plain impedance load. The shaft load of induction and synchronous motors is independent of voltage, and for these, the maximum power limit and stability limit coincide. Thus, a composite load would have greater stability than a pure shaft load of the same amount.

H. H. Dewey: In closing, I shall take up some of the points that have been brought up in the discussion of the paper by Mr. Doherty and myself.

Mr. Thomas in his discussion brought out a point in regard to the relation of the cost of the terminal apparatus to the cost of the line, pointing out that the line cost was very high per kilowatt. It might run to $125.00 per kilowatt, whereas the terminal apparatus, generators and motors, would be very much less than that, perhaps $8.00 or $10.00 per kilowatt, and that since the terminal apparatus was an important factor in the power limit of the completed system, the place to work to extend our power limits was on the synchronous apparatus. I agree with that thoroughly, and we can do considerable along that line.

Mr. Evans and Mr. Fortescue spoke of the possibilities of synchronous-apparatus improvement as a thing about which we were unduly pessimistic in our paper, that is, the question of what could be done to increase the power limit of terminal apparatus. Our paper did not stress that point for the reason that it seemed obvious. In presenting the curve given, showing the breakdown of a given generator and a given motor, it is quite apparent that the power limit is determined by the size of the generator. If we had a generator of double the size, or a motor of double the size, we would get double the power. In line with Mr. Thomas' suggestion then, since we can put on generating apparatus for $8.00 or $10.00 per kilowatt, we can obviously increase the size of the generator until we strike an economic balance between the size of the generator and the capacity of the line.

Now, the size of a generator is determined by its characteristics. We would fool ourselves if we tried to take a 10,000-kilowatt generator and cut its reactance in half, change its field, style, etc., and still call it a 10,000-kilowatt generator. It wouldn't be a ten thousand any more; it would be fifteen or twenty, and it would cost more money to build it. That is an obvious thing that we did not stress in our paper. Since generating and receiving apparatus is a large factor in limiting the power that can be transmitted over a system, everything possible should undoubtedly be done to improve their characteristics.

The paper tried to cover the essential points in determining what a given set-up would give. There was a point that Mr. Evans brought up and Mr. Fortescue also, in their discussion, in regard to the effect of charging current of transmission lines. They took issue with Mr. Doherty and myself in stating that charging current was an actual detriment. They evidently did not read our discussion of that point very carefully.

With given apparatus, with a given generator, with a given receiving-motor load, and a given voltage, at each end of the line, which we always have, charging current *is* an absolute detriment. We reduce the amount of power which can actually be transferred from the generator to the receiver end, no matter what the relation of charging current of the line to the generator. The charging current of the line on a high-voltage system will actually reduce the amount of power you can transfer from the generators to the motors, because it reduces the excitation of the generators and motors.

Mr. Evans brought out a point in which he indicated that our calculations on a 250-mi. line were in error in that it was considerably less than the value that had already been obtained in practise by the Southern California Edison Company. He stated that our calculations showed the limit to be 115,000 kw. whereas they obtained 183,000 kw. The calculation is 120,000 kw., not 115,000 as read from the curve by Mr. Evans. We have made a calculation of the Southern California Edison System based upon data furnished by Mr. Barre which showed 183,000 kw. Our check calculations, made in the same manner as our calculations in the paper, came within 5 per cent or thereabouts of the same results.

The big difference in these values comes in this respect: The 120,000 kw. shown in the paper was receiving load. The 183,000 kw. obtained in actual practise on the Southern California Edison Company's system was at the generating end. At the time they had 183,000 kw. input they had 135,000 kw. output. Thus, we have an error of only 120,000 kw. to 135,000 kw. and there is a difference of 20 per cent in frequency, that is, 50 instead of 60 cycles, which brings it to almost exactly the same thing.

Mr. Wood spoke of the term that has been quite often used to describe "power limit;" that is, "instability," and sounded a warning against its use. I agree with him thoroughly on that. It was for that reason that the title of our paper was made Power Limit. Power limit is something that is perfectly harmless,

and I agree that the use of the word instability is likely to cause concern where concern is not necessary.

Mr. Fortescue's discussion was quite lengthy and very helpful. He took issue with some parts of our paper. Some of these points I did not quite digest. Some of them made me rather think that he was saying the same thing we were saying only in different words, particularly as he laid very great stress on the effect of voltage regulators. I agree with him thoroughly that the regulator is a very important thing, and is so much more important than we originally thought that it makes a great deal of difference in the ultimate capacity of the transmission system.

We have very few real things to worry about. I agree with Mr. Wilkins that the final solution of this problem is going to come in the data that we get from actual operation, but so far the data of actual operation, where we have been able to obtain data, have checked so closely with our present methods of calculation that we feel we are in a position where it will be possible to predict what will happen to any given system. The more complicated the system, the more difficult it is to calculate, and when we get such complications, we must resort to some scheme such as Mr. Nickle has described[9], just as we reach the limit of the possibility of calculating short-circuit current on a network such as described by Mr. Wilkins with 880,000 kw. of generating capacity and thousands of miles of interconnected transmission line. That would be a hopeless case to calculate the short-circuit current, but we have calculating machines that arrive at these values very closely. We can likewise use the Nickle calculator, or some other device to arrive at our stability problem. We are not worrying about the question of stability or power limits; we know pretty closely how to calculate them, and it is very essential that we do so, as the amount of power that can be carried over a given line greatly influences the cost of delivered power.

C. L. Fortescue: In regard to Mr. Thomas' discussion, he emphasizes the effect of damping factors. In our calculations we try to work in the effect of the damping factor as much as possible, but Mr. Thomas remarks that if you increase the damping factor sufficiently the machine will be critically damped. We know that in practise this condition is never met. We have records of power swings and they are as far as we know never critically damped.

As regards Mr. Doherty's discussion I think we are substantially in agreement. I think an explanation of the differences in view might be somewhat as follows:

Two investigators have approached this problem from somewhat different angles, and while there is no disagreement in the fundamentals of the problem, there is a little apparent disagreement in what might be termed derived ideas.

The problem of stability involves so many factors, the speed of the exciters, the speed of the regulators, the inherent tendency of the machines to correct themselves, etc., that it is quite excusable that there should be a slight difference of opinion.

Now, I think you might say that Messrs. Doherty and Dewey and myself agree on what should be. We probably agree pretty well on what actually is, but we disagree somewhat in regard to what may be or might be, Messrs. Dewey and Doherty putting the "might be" a little closer to the "is," and I myself putting the "might be" a little closer to the "should be."

I hope that the result of our investigations will finally bring us both to an agreement on the "might be" and that the "might be" will finally come closer to the "should be" than Messrs. Doherty and Dewey place it at present. That is my hope. I am quite open-minded about this.

The final decision about this particular question will undoubtedly come about from actual work in the field and in the laboratory. We shall, of course, make calculations and analyze these results and there is no doubt at all that we shall finally come to a substantial agreément. In that day I hope we will be very close to the "should be."

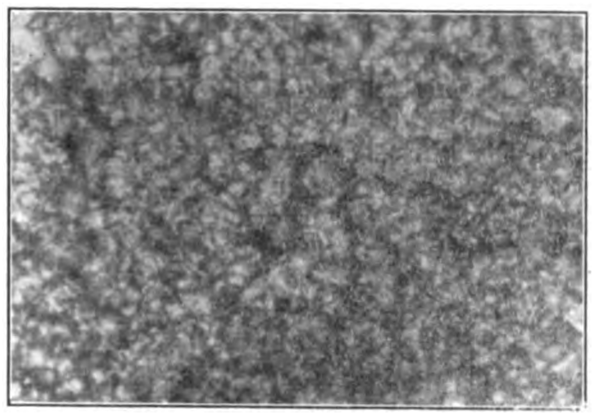
ILLUMINATION ITEMS

By the Lighting and Illumination Committee

INTERESTING ASPECTS OF THE INSIDE FROST LAMP[1]

For some twenty years or more the advantages of frosting an incandescent lamp on the inside of the bulb have been appreciated by illuminating engineers but until recently no satisfactory method had been devised whereby this frost may be applied to the *inside* of the lamp without at the same time greatly weakening the structure of the bulb.

An inside frost is etched into the glass and this etching process causes minute cracks or splits to appear just underneath the surface of the glass. These cracks weaken the strength of the glass in practically the same way as does the scratch made by the hard point of a glass cutter. Moreover they spread easily and cause premature failure just as does a crack in a plate-glass window or in a steel-truss member. It is a well-known fact, however, that if a round hole is drilled at the end of the crack or split in the latter cases the window will be less likely to become entirely broken and the steel supporting member will withstand a greater weight. In like manner, when the inside frosted lamp is subjected to the proper treatment, the entire area of the inside surface will become etched in such a manner as to round out the bottoms of these cracks. The effect in this action is to restore the strength of the bulb to its former value, and the inside frost thus becomes a thing of

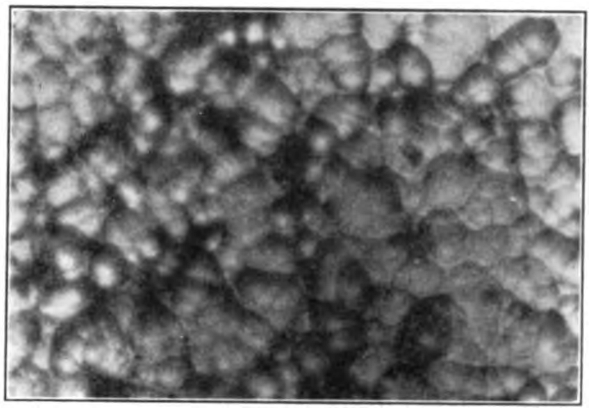


MICROGRAPH SHOWING INSIDE FROSTED SURFACE OF WEAK BULB

1. Marvin Pipkin, Chemist, National Lamp Works of General Electric Co., Nela Park, Cleveland, Ohio.

practical importance instead of theoretical conjecture. The accompanying micrographs show the frosted surface before and after this strengthening action takes place.

The diffusion of the light by the inside frost is obtained by prismatic refraction with comparatively little loss. In fact, the inside frost allows an even greater



Inside Frosted Surface Treated to Restore Strength

portion of the light to pass through than does a similar frost on the outside of the lamp. This is due to the fact that the multiple internal reflections are not so numerous in the inside frosted lamp because the rough, interior surface does not reflect any considerable portion of the light back and forth inside the lamp, as is the case with the outside frosted lamp. Moreover, the relative absorption of the inside frost does not increase so rapidly with the life of the lamp as do other diffusing media. The relative degrees of absorption of the various diffusing media are shown in the following table for new lamps as well as for lamps which have burned for approximately 800 hours.

TABLE NO. I

	Approximate Initial Absorption in per cent of Clear Bulb Light Output	Absorption After Burning in per cent of Clear Bulb Light Output
Inside Frost per cent..	1- 2	1- 5
Sand Frost (Outside) per cent.........	5–10	10–20
Spray Frost (Outside) per cent.........	5–10	10–20
White Mazda (Sprayed) per cent ..	10–15	15–30
Opal Glass...........	10–20	15–30

The light absorption by the inside frost is of little importance when the material reduction in the glare over that from a clear bulb lamp is considered. Other advantages of the inside frost such as the smooth exterior surface of the bulb and the resulting ease with which it may be cleaned, were mentioned in the July issue of the Journal.

When unlighted, the new bulb appears to be a light gray with the property of blending in a harmonious manner with the color of the background that is entirely lacking in the other types of bulb finish. The color of the background is diffused within the lamp, itself, giving it a faint corresponding tint. Because the inside frosted bulb will blend harmoniously with its background, it is hoped that its use will eliminate the necessity of supplying tinted bulbs where the unlighted appearance of the lamp has been an important factor and where the cold white appearance of the outside frosted or coated lamps has been objectionable.

CHAPTERS ON LIGHT

To most of us, the high school physics courses of today are removed somewhat from our general trend of thought. Nevertheless, let us consider them for the moment. They are essentially the same as they were some years ago—fair enough, perhaps, in some branches of physics since Archemedies' principle, Charles' and Boyles' laws, Newton's laws of motion and the like, are fundamental truths which will never change as far as we are concerned. But what about these chapters in the physics texts which deal with light—that vision-giving wave motion by means of which we are able to see what goes on about us?

Unfortunately, the majority of high school physics texts treat the subject of light in a rather dry and scientific manner which quite frequently presents no direct appeal to the average high school student. Realizing this, the Illuminating Engineering Society has prepared a booklet, "Chapters on Light," which is recommended for inclusion in physics text books. The preparation of this booklet has been sponsored by several of the most prominent illuminating engineers of the country and it is therefore up-to-date in every detail. Furthermore, the presentation of the subject matter is such that the average high school student will be directly interested in the practical applications of lighting and illumination to every-day life, and he is, therefore, much interested in the laboratory experiments which will really be of some practical benefit to him.

"Chapters on Light" will make an excellent addition to present text books and may be used in part as a substitute for present material. It is hoped that this booklet will be used more extensively in high school physics courses as it will undoubtedly tend to increase the students' interest in correct lighting and its application.

JOURNAL
OF THE
American Institute
of Electrical
Engineers

PUBLISHED MONTHLY BY THE A. I. E. E.
33 West 39th Street, New York
Under the Direction of the Publication Committee

M. I. PUPIN, *President*
GEORGE A. HAMILTON, *National Treasurer*
F. L. HUTCHINSON, *National Secretary*

PUBLICATION COMMITTEE
L. F. MOREHOUSE, *Chairman*
F. L. HUTCHINSON
E. B. MEYER
DONALD MCNICOL
J. H. MORECROFT

GEORGE R. METCALFE, *Editor*

Subscription. $10.00 per year to United States, Mexico, Cuba, Porto Rico, Hawaii and the Phillipines; $10.50 to Canada and $11.00 to all other countries. Single copies $1.00. Volumes begin with the January issue.

Changes of advertising copy should reach this office by the 15th of the month for the issue of the following month.

The Institute is not responsible for the statements and opinions given in the papers and discussions published herein. These are the views of individuals to whom they are credited and are not binding on the membership as a whole.

A. I. E. E. Nominations

The National Nominating Committee of the Institute met at Institute headquarters, New York, December 3, and selected a complete official ticket of candidates for the Institute offices that will become vacant August 1, 1926.

The committee consists of fifteen members, one selected by the executive committee of each of the ten Geographical Districts, and the remaining five elected by the Board of Directors from its own membership.

Those present were: H. P. Cramer, Portland Ore.; W. P. Dobson, Toronto, Ontario; Gano Dunn, New York, N. Y.; G. Faccioli, Pittsfield, Mass.; M. M. Fowler, Chicago, Ill.; J. E. Kearns, Chicago, Ill.; M. M. Koch, Denver, Colo.; E. B. Merriam, Schenectady, N. Y.; L. F. Morehouse, New York, N. Y.; A. G. Pierce, Cleveland, Ohio; T. C. Ruhling, Kansas City, Mo.; A. M. Schoen, Atlanta, Ga.; Harold B. Smith, Worcester, Mass.; N. W. Storer, Pittsburgh, Pa.; H. S. Warren, New York, N. Y. (representing Pacific District); and National Secretary F. L. Hutchinson. Mr. Gano Dunn was unanimously elected chairman of the committee.

The following is a list of the official candidates:

FOR PRESIDENT

Cummings C. Chesney, Manager and Chief Engineer, General Electric Company, Pittsfield, Mass.

FOR VICE-PRESIDENTS

NORTH EASTERN DISTRICT: H. M. Hobart, Consulting Engineer, General Electric Company, Schenectady, N. Y.

NEW YORK DISTRICT: George L. Knight, Mechanical Engineer, Brooklyn Edison Company, Brooklyn, N. Y.

GREAT LAKES DISTRICT: B. G. Jamieson, Engineer of Inside Plant, Commonwealth Edison Company, Chicago, Ill.

SOUTH WEST DISTRICT: A. E. Bettis, Vice-President, Kansas City Power & Light Company, Kansas City, Mo.

NORTH WEST DISTRICT: H. H. Schoolfield, Chief Engineer, Pacific Power & Light Company, Portland, Ore.

FOR MANAGERS

F. J. Chesterman, Chief Engineer, Bell Telephone Company of Pennsylvania, Philadelphia, Pa.

H. C. Don Carlos, Operating Engineer, Hydro-Electric Power Commission of Ontario, Toronto, Ont.

I. E. Moultrop, Asst. Supt., Construction Bureau, Edison Electric Illuminating Company of Boston, Boston, Mass.

FOR TREASURER

George A. Hamilton, Electrical Engineer, Elizabeth, N. J.

The constitution and by-laws of the Institute provide that the nominations made by the National Nominating Committee shall be published in the January issue of the Institute JOURNAL; and provision is made for independent nominations as indicated below:

CONSTITUTION

SEC. 31. Independent nominations may be made by a petition of twenty-five (25) or more members sent to the National Secretary when and as provided in the By-Laws; such petitions for the nomination of Vice-Presidents shall be signed only by members within the District concerned.

BY-LAWS

SEC. 22. Petitions proposing the names of candidates as independent nominations for the various offices to be filled at the ensuing election, in accordance with Article VI, Section 31 (Constitution), must be received by the Secretary of the National Nominating Committee not later than February 15 of each year, to be placed before that Committee for the inclusion in the ballot of such candidates as are eligible.

On the ballot prepared by the National Nominating Committee in accordance with Article VI of the Constitution and sent by the National Secretary to all qualified voters during the first week in March of each year, the names of the candidates shall be grouped alphabetically under the name of the office for which each is a candidate.

F. L. HUTCHINSON,
Secretary
National Nominating Committee

Cummings C. Chesney

Mr. Chesney, official nominee for the office of President of the Institute, was born in Selingsgrove, Pa., October 28, 1863, and was graduated from the Pennsylvania State College in 1885. After teaching mathematics and chemistry for three years he became associated with Mr. William Stanley's laboratory at Great Barrington, Mass., and was one of the original incorporators of the Stanley Electric Manufacturing Company, of Pittsfield, Mass., which developed the well-known S K C polyphase system (Stanley-Kelly-Chesney). Mr. Chesney was vice-president and chief engineer of the Stanley Company from 1904 to 1906, and in the latter year he became chief engineer and manager of the Pittsfield Works of the General Electric Company, which had acquired the Stanley Company. Mr. Chesney has served as Manager and Vice-President of the A. I. E. E., and also upon various committees. He is also a member of various other scientific and engineering organizations. The Edison Medal was awarded to Mr. Chesney in 1921 "for early developments in alternating-current transmission."

Plans for the Midwinter Convention

FEBRUARY 8-11, 1926

A variety of excellent papers will be presented at the Midwinter Convention which will be held in the Engineering Societies Building, 33 West 39th Street, New York, February 8-11, 1926. The entertainment and social features as well as the inspections will be thoroughly enjoyable.

Among the technical subjects to be discussed are transmission stability, protective and control systems, bus and structural construction, electrical machinery, measurements, insulation and dielectric absorption, electromagnetism and electrophysics, communication and sound reproduction, and furnace-resistor design. The list of papers given below shows in detail the topics to be presented.

In the social part of the program there will be an informal smoker on Tuesday evening, February 9, at the Hotel Astor. Some very interesting entertainers will add to the pleasure of this evening.

The dinner-dance on Wednesday evening promises to be even better than the dinner-dances of the past few years which always have been most heartily enjoyed. This event will be held at the Hotel Astor and a Paul Whiteman orchestra will furnish the music. This fortunate combination is an absolute guarantee of an excellent dinner, fine music and very enjoyable dancing.

On Thursday evening an address will be given by a prominent speaker and all should take the opportunity of hearing him.

New York, of course, offers a limitless variety of possible inspection trips and the trips being arranged will be most instructive. Among the places to be visited will be the new Holland Tunnel (the vehicular tunnel under the Hudson River), Broadcasting Station W. E. A. F. of the American Telephone and Telegraph Company, the Edison Lighting Institute of the Edison Lamp Works, the Loening Airplane Factory, Kearny Power Station of the Public Service Electric and Gas Company, Hudson Avenue Station of the Brooklyn Edison Company, Hell Gate and Sherman Creek Stations of the United Electric Light and Power Company, the Bell Telephone Laboratories and a machine-switching central telephone office.

A live convention committee is perfecting plans to assure that all who attend the meeting will have a pleasurable and profitable time. The general committee appointed by President Pupin is as follows: H. A. Kidder, Chairman. H. H. Barnes, Jr., G. L. Knight, E. B. Meyer and L. F. Morehouse. Chairmen in charge of entertainment features are as follows: Smoker, G. W. Alder; Inspection Trips, H. Y. Hall; Dinner-Dance, J. B. Bassett, and Special Meeting, H. S. Sheppard.

Reduced Railroad Rates

A reduction in railroad fares is available to out-of-town visitors under the certificate plan. Under this plan each person requests a certificate when purchasing a one-way ticket to New York. Presentation of this certificate at convention headquarters will entitle the passenger to half-rate fare for the return trip by the same route provided 250 certificates are presented at the convention.

Members should advise their local ticket agents when purchasing tickets of their intention to attend the A. I. E. E. convention and should ask for certificates. Return tickets issued at the reduced rates are not acceptable on a few limited trains. Tickets must be purchased not more than a fixed number of days prior to the opening date of the meeting and return tickets must be used within a certain period after the closing date. Details relative to these dates, etc., can be obtained from ticket agents. Immediately on arrival in New York certificates should be presented to the endorsing officer at convention headquarters.

All Visitors Should Get Certificates

Everyone, whether he will use it or not, should get a certificate if his regular fare to New York is 67 cents or more, because all certificates presented will count toward the 250 required to give reduced fares to those coming long distances.

TENTATIVE PROGRAM OF MIDWINTER CONVENTION FEBRUARY 8-11, NEW YORK

Monday Morning

Registration
Committee Meetings

Monday Afternoon

Transmission Session

1. *An Investigation of Transmission-System Power Limits*, C. A. Nickle, General Electric Company, and F. L. Lawton, Quebec Development Company.

   Results of theoretical analysis, verified by miniature-system tests, of the power limits of transmission systems. Among the major conclusions are the following: (1) The criterion of stability for all conditions is the steady-state power limit, (2) the charging kv-a. exercises marked detrimental effects on stability, (3) the characteristics of synchronous terminal apparatus are of great importance, (4) improvements can be made by modifying present apparatus design, (5) automatic voltage regulators, suitable exciters and fast relays are essential, and (6) the mercury-arc rectifier as an adjunct in excitation circuits shows real advantages.

2. *Calculation of Steady-State Stability in Transmission Lines*, Edith Clarke, General Electric Company.

   Two simple methods of determining whether a proposed transmission system will or will not be stable for steady-state operation under the maximum proposed load, (1) by means of an equivalent circuit and (2) by means of a circle diagram. Examples are solved to illustrate the methods.

3. *Practical Aspects of System Stability*, Roy Wilkins, Pacific Gas and Electric Company.

   An account of field tests made on a 220-kv. transmission system to determine the behavior of the system under transient conditions. Among several important conclusions reached are: (1) Stability is inextricably entangled with system economics, (2) studies of artificial systems are not adequate, (3) only a certain part of a system's stored energy is available during trouble, (4) proper relay action is vital, and (5) operating distribution of exciting current is a major problem.

4. *Further Studies of Transmission Stability*, R. D. Evans and C. F. Wagner, Westinghouse Electric & Mfg. Company.

   This paper deals with the principal elements entering into the stability problem, such as the action of generators and exciters during disturbances, effect of dissymmetry produced by single-phase short circuits, simplification of load networks, and methods of combining these factors in determining electro-mechanical oscillations following disturbances. Results of calculations are compared with recent tests on the Pacific Gas and Electric Company system. Various methods of improving stability are discussed.

5. *Transmission Systems with Over-Compounded Voltages*, H. B. Dwight, Massachusetts Institute of Technology.

   A discussion of the advantages of causing the voltage at generating stations to be raised by automatic regulation at times of heavy load. Methods of calculation for the transmission line and transformers for over-compounded operation are given. Two methods are given (1) for over-compounded generator voltage and constant receiver voltage and (2) for over-compounded voltages at both generator and receiver.

Monday Evening

Dielectrics and Insulation

6. *Dielectric Absorption and Theories of Dielectric Behavior*, J. B. Whitehead, Johns Hopkins University.

   A review and comparison of all the theories of dielectric behavior and dielectric absorption which are found in existing literature. This is a report made on these subjects to the Division of Engineering and Industrial Research of the National Research Council. An exhaustive bibliography is included.

7. *Theory of Absorption in Solid Dielectrics*, V. Karapetoff, Cornell University.

   The purpose of this paper is to establish certain general relations between (a) the increase in electrical displacement in a solid dielectric and (b) time after the initial displacement which occurs almost instantly after applying a constant d-c. voltage.

The ultimate aim of the theory is to make it possible to correlate and mutually to check experimental data on absorption and dielectric loss and to predict these quantities where no test figures are available.

8. *Ionization Studies in Paper-Insulated Cables*, C. L. Dawes and P. L. Hoover, Harvard University.

Tests data are given in this paper which show the relations among voltage, power factor, watts, capacitance and temperature in impregnated-paper cables and in model cables. A new type of a-c bridge for measuring dielectric loss and power factor with great accuracy at very low power factors is described. Some new and interesting conclusions have been drawn from the results and theories formulated to account for the results.

Tuesday Morning

Protection, Control and Bus Construction

9. *Operating Performance of a Petersen Earth Coil-II*, J. M. Oliver and W. W. Eberhardt, Alabama Power Company.

A record of eleven months' operating experience with a Petersen earth coil installed on a 44,000-volt transmission system. A compilation of system troubles is given showing how often the coil functioned correctly or incorrectly. In 109 cases of insulator flashover the coil operated correctly in 94 cases.

10. *Theory of the Auto-Valve Lightning Arrester*, Joseph Slepian, Westinghouse Electric & Mfg. Company.

A discussion of the advantages of the valve-type arrester for protection of high-voltage power systems. The theory of the autovalve arrester is given including a discussion of the breakdown potential of very short gaps.

11. *Current-Limiting Reactors with Fire-Proof Insulation on the Conductor*, F. H. Kierstead, General Electric Company.

This paper describes tests made to determine the proper insulation to use to prevent flashovers of current-limiting reactors due to conducting objects accidentally lodged between the turns. The paper describes (a) short-circuit tests to determine the insulation necessary and (b) thermal tests to determine the fire-resisting characteristics of the insulation.

12. *Temperature Rise and Losses in Structural-Steel Members Exposed to the Fields from A-C. Conductors*, O. R. Schurig and H. P. Keuhni, General Electric Company.

Results of an experimental investigation to obtain practical data on the temperature rises and losses in various structural-steel members when exposed to the fields from a-c. conductors. Should be useful to designers in making estimates of temperature rise and avoiding construction in which heavy losses would occur. Data are given which will serve as a basis for designing copper sleeves to minimize heating and losses in iron members.

13. *Carrying Capacity of Sixty-Cycle Busses for Heavy Currents*, Titus G. LeClair, Commonwealth Edison Company.

This paper describes tests on grouped copper busses carrying very large phase currents. It shows how with very high currents the usual arrangement becomes quite inefficient on account of unequal distribution of current. Special arrangements of bus bars are suggested which have much greater current-carrying capacity. One arrangement shows a three-phase bus which carried 8500 amperes per phase with 30 deg. cent. rise.

14. *Supervisory Systems for Electric Power Apparatus*, Chester Lichtenberg, General Electric Company.

A general survey and description of the various types of supervisory systems for control and indication of remotely located electrical apparatus. The systems described are classed as follows, (1) selector, (2) distributor, (3) audible, (4) code-visual, (5) synchronous-relay-visual and (6) carrier-current. The principles and features of each system are discussed. Also the supervisory system is compared with the better known remote-control system. Telemetering also is covered.

Tuesday Afternoon

Two Parallel Sessions, A and B

(A) Electrical Machinery

15. *Experimental Determination of Losses in Alternators*, Edouard Roth, Societe Alsacienne de Constructions Mecaniques.

This paper presents some studies made to find accurate and simple methods of determining the losses in large electrical machines, particularly alternators. The studies were undertaken because it was felt that the separate-loss method when used for determining the efficiency of large machines does not give correct results.

16. *No-Load Copper Eddy-Current Losses*, Thomas Spooner, Westinghouse Electric & Mfg. Company.

This paper is an attempt to place on a firm theoretical foundation the calculation of no-load copper eddy-current losses. Test results are presented to show that the theoretical formulas developed are correct. Some of the consequences of this analysis are rather unexpected where the frequencies are sufficiently high to produce large skin effect. For instance laminating the copper may increase or decrease the losses depending on conditions.

17. *Mechanical Force Between Electric Circuits*, R. E. Doherty and R. H. Park, General Electric Company.

In this paper a general equation is developed for the mechanical forces exerted by electric circuits containing inductances which are functions both of position and of current. The equation is applicable to circuits involving saturated iron. The results are to be used in investigating the forces in synchronous machines under short-circuit conditions.

18. *Concluding Study of Ventilation of Turbo-Alternators*, C. J. Fechheimer and G. W. Penney, Westinghouse Electric and Mfg. Company.

An investigation by means of models of a method of ventilating turbo-alternators. Test results, the methods of determining the losses and the equations derived are given.

(B) Communication and Sound Reproduction

19. *The Development and Application of Loading of Telephone Circuits*, William Fondiller, Western Electric Company and Thomas Shaw, American Telephone & Telegraph Company.

A review of the art of loading telephone circuits as practised in the United States. Loading is discussed in relation to developments during the last 14 years pertaining to (1) phantom group loading, (2) loading for repeatered circuits, (3) incidental cables in open-wire lines, (4) crosstalk, (5) telegraphy over loaded telephone circuits, (6) loading for exchange-area cables and (7) submarine cables.

20. *Automatic Enciphering and Deciphering Systems.*, G. S. Vernam, American Telephone and Telegraph Company.

This paper describes a printing telegraph cipher system developed during the World War for use of the Signal Corps, U. S. Army. The system is so designed that the messages are in secret form from the time they leave the sender until they are deciphered automatically at the office of the addressee. If copied en route the messages cannot be deciphered by the copier even though he has full knowledge of the method used.

21. *Refraction of Short Radio Waves in the Upper Atmosphere*, W. R. G. Baker and C. W. Rice, both of General Electric Company.

Estimation of the most suitable wave lengths for night or day communication between any two points is made possible by the theory and calculations proposed in this paper. The paper shows first how the striking phenomena of short-wave radio transmission (below 60 meters) can be quantitatively accounted for by a simple electron-refraction theory. The paths taken by waves from an antenna to distant points on the earth's surface are calculated. Ideal signal-intensity curves are given which show how the transmitted energy is distributed over the earth's surface. Reflection at the surface also is considered.

22. *High-Quality Recording and Reproducing of Music and Speech*, J. P. Maxfield and H. C. Harrison, Bell Telephone Laboratories, Inc.

An analysis of the general problem of recording and reproducing sound with particular reference to the phonograph. A very definite design of mechanical parts is made possible by substituting in the analysis electrical analogs for mechanical parts and functions. The theory of electrical filters is applied to these analogs and is of great assistance in determining the desired mechanical wave-transmission system for high-quality recording and reproduction.

Tuesday Evening

Smoker

Wednesday Morning

Electrical Machinery

23. *Parameters of Heating Curves of Electrical Machinery*, V. Karapetoff, Cornell University.

In this paper it is pointed out that an electrical machine, for thermal purposes cannot be considered as a single body. In a rotating machine the stator consists of two metal bodies between which there may be a temperature difference and the same is true of the rotor; besides there is a mutual heat flow between stator and rotor. In a transformer three separate metal bodies at different temperatures may be distinguished.

24. *Rating of Electrical Machinery as Affected by Altitude*, C. J. Fechheimer, Westinghouse Electric & Mfg. Company.

It is known that an electrical machine carrying a given load becomes hotter at high altitude than it does at sea level. This paper proposes equations to show how the temperature increases with elevation. Also equations are given for the corollary case, namely, to show how the rating must be decreased at high altitude for the same temperature rise as normally occurs at sea level. The paper discusses the rules of the A. I. E. E. Standards on this point.

25. *Motor Band Losses*, Thomas Spooner, Westinghouse Electric & Mfg. Company.

This paper shows that railway-motor band losses are of appreciable magnitude, sometimes large enough to be detrimental to thS cooling of the motor. Band losses are shown to vary accordine to (a) the 1.7 power of the frequency and (b) the 1.35 to the 1.g power of the induction.

26. *Starting Characteristics of Polyphase Squirrel-Cage Induction Motors and Their Control*, H. M. Norman, Westinghouse Electric & Mfg. Company.

The characteristics of squirrel-cage induction motors during starting, stopping and reversing are discussed in this paper. Equations are given which allow a comparison to be made between loss and time of acceleration. These equations are useful in determining the best value of secondary resistance for a certain application. Short methods are given for determining time of acceleration and moment of inertia of rotors.

WEDNESDAY AFTERNOON

Inspection Trips

WEDNESDAY EVENING

Dinner-Dance, (Hotel Astor)

THURSDAY MORNING

ELECTROMAGNETISM AND PHYSICS

27. *Calculation of Magnetic Attraction*, Th. Lehmann, Consulting Engineer.

A description of a simple and practical way of surveying and appraising the magnetic force in an air gap by means of the theory of the potential function. The author decomposes the magnetic field into elemental tubes of magnetic force whose envelopes enclose spaces in which the magnetic density is constant.

28. *The Magnetic Hysteresis Curve*, Hans Lippelt, with Thomas E. Murray, Inc.

An analysis of the phenomena of hysteresis introducing the conception of a reactive component and a dissipative component of the counteractive force which acts when magnetic material is subjected to a magnetizing force. Equations and curves are developed which show how these components vary with variations of the magnetizing force.

29. *Properties of the Single Conductor*, Carl Hering, Consulting Electrical Engineer.

In this paper the properties of a unit length of single, straight conductor far removed from all other circuits are investigated in an endeavor to find whether such a unit is a basic, fundamental one on which deductions and a method of mathematical treatment could be based. A constant is deduced for the energy stored by a current in such a unit length, which seems to be one of the most fundamental, basic constants in electrodynamics, from which many useful deductions can be made. This energy corresponds to the $mv^2/2$ of moving masses. It is shown that what might be called "wattless flux" should be recognized, and that "self-inductance" is used in two senses which may sometimes lead to different results.

30. *Heaviside's Proof of His Expansion Theorem*, M. S. Vallarta, Massachusetts Institute of Technology.

Heaviside's proof of his Expansion Theorem found scattered in his "Electrical Papers" is reconstructed in this paper. It is based on his so-called "conjugate theorem" which establishes a relation between any two normal modes of oscillation of a dynamical system. The relations between Heaviside's, Carson's and Wagner's proofs are pointed out.

THURSDAY AFTERNOON

MEASUREMENTS, MACHINERY AND INDUSTRIAL

31. *A New Wave-Shape Factor and Meter*, L. A. Doggett, J. W. Heim and M. W. White, all of Pennsylvania State College.

A meter for determining wave-shape factor is described in this paper. This meter is claimed to have advantages over the method of analysis based on oscillograms. The advantages come under the following headings: (1) cost, (2) portability, (3) ease of experimental procedure (4) rapidity of obtaining results and (5) accuracy and consistency. The meter consists essentially of a star-connected circuit consisting of two voltmeters and a variable condenser.

32. *Practical Application of Vibration Instruments to Rotating Electrical Machines*, J. Ormondroyd, Westinghouse Electric & Mfg. Company.

The possibilities of using vibration instruments in testing rotating electrical apparatus are outlined in this paper. The advantages of vibration-type instruments for certain purposes and an outline of instruments adapted to the various uses are discussed.

33. *Use of High Frequency for Testing Insulation of Rotating Apparatus*, R. E. Ferris and J. L. Rylander, both of Westinghouse Electric and Mfg. Company.

This paper tells of the advantages of using high-frequency voltage for testing the insulation between the turns of coils or windings. By the use of high frequency, high voltages may be applied between turns. This method has been found useful as a shop method for checking defects in material and poor workmanship.

34. *The Cross-Field Theory of Alternating-Current Machines*, H. R. West, General Electric Company.

This paper shows how a general plan of analysis following the cross-field theory may be applied to a-c. motors to obtain simple and accurate numerical methods for routine calculations of performance characteristics. To explain the details and application of the method two examples are worked respectively for a single-phase induction motor and a repulsion motor.

35. *Rating of Heating Elements for Electric Furnaces*, A. D. Keene and G. E. Luke, both of Westinghouse Electric & Mfg. Company.

An experimental study of the effective heat produced by various arrangements of resistor heating elements such as used in electric ovens and furnaces. The effects of spacing, resistor shape, shielding, radiation and reflection are studied. The resultant data obtained should be useful in designing ovens and furnaces.

THURSDAY EVENING

Address by prominent speaker.

Five Regional Meetings Planned For Coming Year

The Regional Meeting idea has worked out so successfully in the Institute that three, and possibly five, of these meetings will be held during the year 1926. Meetings will be held in Cleveland, Niagara Falls, and Madison, Wis., during the first half of the year; and possibly in New York and Kansas City during the latter half.

Very fine programs are contemplated for all these meetings and technical papers of the highest quality will be presented. Authors of high-grade papers are realizing that their papers will be well received and ably discussed at the regional meetings. There are two advantages to presenting a paper at a regional meeting. The first results from the fact that papers are selected which will be of particular interest in the locality where the meeting is held, and therefore the audience will be responsive. The second advantage is that ample time is allowed for discussion. These papers are given the same treatment and publication rights as are papers for the so-called national conventions.

The plans for the contemplated meetings are given in the following paragraphs.

Cleveland Regional Meeting March 18 and 19

Sectionalized electrical drive and electrical refrigeration will be the principal technical topics discussed at the regional meeting which will be held under the Second District of the Institute at Cleveland on March 18 and 19. The social side of the meeting has been well planned and trips of inspection also will be made. The Hotel Cleveland will be headquarters.

The technical papers on sectionalized electrical drive will deal specifically with application to paper-making machines, but on account of the great possibilities of applying synchronized drives in other industries it is felt that these papers will attract to the meeting many engineers connected with rubber mills, textile

mills, wire mills, coal-handling, conveying, automobile production, etc. Three papers on this subject will be presented on March 18 by representatives of the three manufacturers who make equipment for this purpose. The authors will be H. W. Rogers of the General Electric Company, S. A. Staege of the Westinghouse Electric and Manufacturing Company, and R. N. Norris of the Harland Engineering Company.

A paper on Electrical Refrigeration will be presented on March 19 by C. F. Kettering, president of the General Motors Engineering Corporation. This will be followed by an address by Dr. Farley Osgood, Past-President of the Institute on The Human Side of Engineering.

Ample time for very full discussion will be allowed on all the papers presented at this meeting as the committee in charge has arranged the program with this object particularly in view.

A dinner will be held on the first evening at which two addresses will be delivered. These will probably be given by City Manager Hopkins of Cleveland and John Stanley, president of the Cleveland Railway. A number of inspection trips will be available, the main trip being one on the second evening to the Nela Park laboratories.

Arrangements for the meeting are being made by a competent general committee which is as follows: Chairman, A. M. MacCutcheon; Secretary, C. S. Ripley; A. G. Pierce, Vice-President of District No. 2; C. L. Dows, Ralph Higgins, A. F. E. Horn and Nathan Shute.

Madison Meeting in May

Rural electrification, interconnection between power systems, cooperative research relations between colleges and industries, and underground distribution developments will be featured on the program of the regional meeting to be held in Madison, Wis., early in May. Various other subjects also will be covered. This will probably be a two-day meeting. The officers of District No. 5 are progressing with further details of the plans.

Niagara Falls Meeting, May 26-28

A three-day meeting with a wide variety of technical topics will be held by District No. 1 at Niagara Falls, N. Y., May 26, 27 and 28. A number of important engineering subjects will be covered and a full program of social and entertainment features is contemplated.

The technical subjects will include methods of dielectric-loss measurements, transmission, power plants and a number of other topics.

Plans are being made for a special illumination of the Falls, a trip down the Gorge, visits to power plants, a dinner and entertaining addresses of general interest. Further details will be published in later issues.

Future Section Meetings

Boston

Latest Design and Practise in Power Plants, by Vern E. Alden, Consolidated Gas, Elec. Lt. & Pr. Co. Lorimer Hall, Tremont Temple. Joint meeting with A. S. M. E. January 14.

High-Tension Cable Testing, by F. M. Farmer, Electrical Testing Laboratories. Meeting to be held in the new 750,000-volt testing laboratory of the Simplex Wire & Cable Co., Boston, Mass. February 19.

Connecticut

Maintenance of Industrial Equipment. Hartford. January 19.

High-Voltage. New Haven. January 29.

Patents. Stamford. February 9.

Lehigh Valley

Research of Today, the Engineering of Tomorrow, by E. B. Craft, Bell Laboratories, Inc. Joint meeting with Engineers' Club, Lehigh University Branch and Lafayette College Branch. Easton, Pa. January 20.

St. Louis

Long-Distance Cable Communication for St. Louis, by H. H. Nance, American Tel. & Tel. Co. January 20.

New York

The next meeting of the New York Section of the A. I. E. E. will be held at 8:15 p.m., Friday, January 29, 1926, Auditorium, Engineering Societies Building, 33 West 39th Street, New York, and will be devoted to a subject of inherent interest to every engineer,—in fact to the general public itself,—"The Trend of the Electric Light and Power Industry." The meeting will be based on an analysis and discussion of the prize winning papers in the essay contest, conducted last Spring by Bonbright and Company.

The Meetings and Papers Committee has been successful in obtaining several very prominent speakers:

Robert M. Davis, Statistical Editor of the *Electrical World* and second prize winner in the contest will give a statistical analysis or survey of the field, including an analysis of the 1925 operating figures which will then be available.

H. P. Liversidge, Vice-President of the Philadelphia Electric Company, will discuss the engineering possibilities and probabilities in the industry's development.

John F. Gilchrist, Vice-President of the Commonwealth Edison Company, will discuss the commercial policies and probable developments.

H. V. Bozell, of Bonbright & Company, will cover the financial questions.

Other speakers of prominence will probably take part in the general discussion.

Directly preceding the meeting a second get-together dinner will be held at the Fraternity Club, and as accommodations are limited, members of the Section should make an early return of the dinner reservation cards which will accompany the regular notice.

New York Electrical Society to Discuss Long Distance Broadcasting

At a meeting of the New York Electrical Society to be held in the Auditorium, Engineering Societies Building, 33 West 39th St., New York, N. Y., at 8.15 p. m. on the evening of Wednesday, January 6th, 1926, Mr. S. M. Kintner, Manager of Research Dept., Westingthouse Elec. & Mfg. Co., will give an instructive talk on "Long Distance Radio Broadcasting." Short wave length broadcasting is in a very active stage of development and Mr. Kintner is particularly qualified to describe the most recent accomplishments. The talk will be accompanied by some unusually interesting and unique experiments and demonstrations. All interested in this meeting are cordially invited to be present as the guests of the Society.

Annual Meeting of American Society of Civil Engineers

The American Society of Civil Engineers will hold its seventy-third Annual Meeting beginning January 20, 1926, in the Engineering Societies Building, New York, N. Y. The general arrangement so popular in the past will be followed, with business sessions and honorary awards Wednesday morning; reports of the Society's committees Wednesday afternoon; meeting of the Technical Division throughout Thursday and an all-day excursion on Friday, the 22nd.

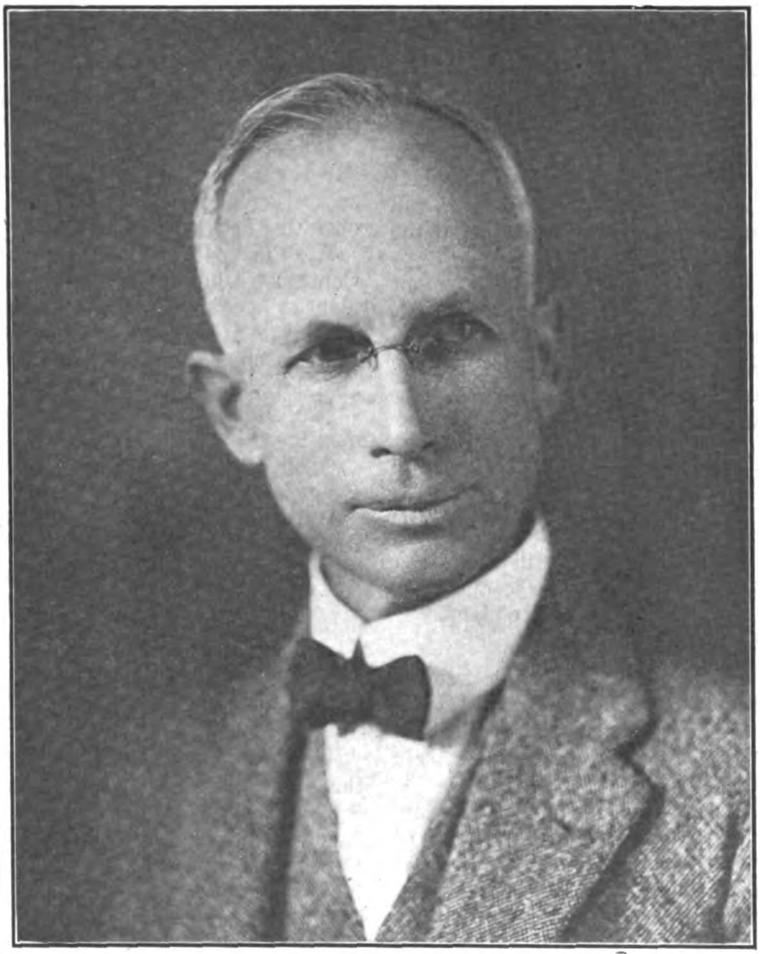
Beside the awards of Society prizes and medals, the Wednesday morning session will embrace the conferring of two honorary memberships—one upon William Barclay Parsons and the other upon Arthur N. Talbot.

A wide range of subjects will be considered in the technical sessions of Thursday, many of them of general as well as national importance.

Edison Medal Awarded Professor Harris J. Ryan

The Edison Medal for the year 1925 has been awarded by the Edison Medal Committee of the Institute to Dr. Harris J. Ryan, Professor of Electrical Engineering, Stanford University, California, "for his contributions to the science and the art of high-tension transmission of power."

Dr. Ryan was born in Powells Valley,, Pa., January 8, 1866 He studied at Baltimore City College 1879 to 1880; Lebannon. Valley 1880 to 1882, and received the degree of M. E. in Electrical Engineering from Cornell in 1887. In 1888 he became a member of the Western Engineering Company at Lincoln, Nebraska, and in 1889 Instructor in charge of the electrical machinery laboratory at Cornell. From 1890 to 1895 he served as Assistant Professor of electrical engineering in provisional charge of the department and from 1895 to 1905 was Professor in charge of the department of electrical engineering. In 1905 he accepted the same position at Stanford University which he holds today. In 1909 Professor Ryan became consulting engineer for the Los Angeles Aqueduct Power Development. During the war as a member of the Pacific Coast Section of the Submarine Group of the National Research Council he carried on valuable work and in 1918 and 1919 was in charge for the Research Council Supersonics Laboratory at Pasadena.



HARRIS J. RYAN

In the Chicago Exposition of 1893 Professor Ryan was a member of the Jury of Awards of the Department of Electricity and in 1904 was a delegate to the International Electrical Congress, St. Louis Exposition. He is a Fellow of the American Association for the Advancement of Science, member of the American Electrochemical Society, Institute of Radio Engineers, Society for Promotion of Engineering Education, American Physical Society and National Academy of Science. In 1887 he was elected an Associate of the A. I. E. E.; in 1895 was transferred to Member and in 1923 became a Fellow. He was a Director of the Institute from 1893 to 1896; Vice-President, 1896 to 1898; Honorary Vice-President representing the Institute at the Panama-Pacific International Exposition, San Francisco, 1915; President, 1923-24; and has served on the Edison Medal, Meetings and Papers, Electrophysics, Transmission and Distribution and Research Committees.

During Professor Ryan's twenty years at Stanford, he has been a pioneering leader in high-voltage transmission, upon the development of which largely depends the future growth of the Pacific Coast region. About three years ago the first 220,000-volt power lines were successfully put into commission by California companies, and Professor Ryan cooperated with the engineers in finding ways to cope with the insulator problems encountered, and it is on the solution of similar problems that his genius in the research field is expected to continue an outstanding advantage to science.

The Edison Medal was founded by the Edison Medal Association, composed of associates and friends of Mr. Thomas A. Edison, and is awarded annually by a committee consisting of twenty-four members of the American Institute of Electrical Engineers for "meritorious achievement in electrical science, electrical engineering, or the electrical arts."

The medal has previously been awarded Elihu Thomson, 1909; Frank J. Sprague 1910; George Westinghouse, 1911; William Stanley, 1912; Charles F. Brush, 1913; Alexander Graham Bell, 1914; Nikola Tesla, 1916; John J. Carty, 1917; Benjamin G. Lamme, 918; W. L. R. Emmet, 11919; Michael I. Pupin, 1920; Cummings C. Chesney, 1921; Robert A. Millikan, 1922; John W. Lieb, 1923; John White Howell, 1924.

First Convention of Radio Engineers

A convention of the Radio Engineers will be held in New York, January 18-19, 1926, when the Institute of Radio Engineers holds its Annual Meeting in the Engineering Societies Building, 33 West 39th Street. Important technical papers will be presented and discussed by engineers prominent in the profession; there will be organized trips of inspection to large radio factories and broadcasting stations, and the convention will close with a banquet at which many of the foremost radio engineers and executives of the country will deliver addresses on up-to-the-minute radio topics.

It is desired that every one identified with the Institute of Radio Engineers will attend one or more of the sessions, and guests are welcome. Chairman of the Convention Committee is R. H. Marriott.

A. I. E. E. Directors Meeting

The regular meeting of the Board of Directors of the American Institute of Electrical Engineers was held at Institute headquarters, New York, on Friday, December 11, 1925.

Officers present were: President M. I. Pupin, New York; Past-President Farley Osgood, Newark, N. J.; Vice-Presidents Harold B. Smith, Worcester, Mass.; A. G. Pierce, Cleveland; Managers H. M. Hobart, Schenectady; G. L. Knight, Brooklyn, N. Y.; H. P. Charlesworth, N. Y.; John B. Whitehead, Baltimore; E. B. Merriam, Schenectady; H. A. Kidder, New York; National Treasurer George A. Hamilton, Elizabeth, N. J., and

National Secretary F. L. Hutchinson, New York; also by invitation: Messrs. A. W. Berresford, J. Franklin Meyer and John B. Taylor.

The minutes of the meeting of the Directors held October 14, 1925, were approved.

Reports of meetings of the Board of Examiners held November 16, and December 7, 1925, were presented and the actions taken at those meetings were approved. Upon the recommendation of the Board of Examiners, the following actions were taken on pending applications: 764 Students were ordered enrolled; 84 applicants were elected to the grade of Associate; 7 applicants were elected to the grade of Member; 1 applicant was transferred to the grade of Fellow; 37 applicants were transferred to the grade of Member.

The Board ratified the approval by the Finance Committee of monthly bills amounting to $18,391.51.

A request from the Executive Committee of the Great Lakes Geographical District, for authority to hold a regional meeting at Madison, Wisconsin, early in May 1926, was approved.

The organization of a Section at Sharon, Pa. was authorized in accordance with a petition from members in Sharon and vicinity.

The organization of a Student Branch at Stevens Institute of Technology, Hoboken, N. J., was authorized.

The Edison Medal Committee reported that the medal for the year 1925, has been awarded to Professor Harris J. Ryan, of Stanford University, Cal., "for his contributions to the science and the art of high-tension transmission of power."

Upon request of the Committee on Education, an appropriation of $600 was made, to apply to the cost of cooperating with the Society for the Promotion of Engineering Education, in an investigation relating to electrical engineering courses in colleges.

Mr. G. L. Knight was appointed a representative of the Institute, upon the Board of Trustees of the United Engineering Society, to succeed H. A. Lardner, whose term will expire in January and who is not eligible for re-appointment.

Professor W. I. Slichter was appointed to succeed himself as a Member of the Library Board of the United Engineering Society, for three years, beginning January 1, 1926.

Messrs. A. G. Pierce, of Cleveland and E. C. Stone, of Pittsburgh, were appointed Alternates, upon the Assembly of the American Engineering Council.

The report of Dr. A. E. Kennelly, who represented the Institute at the Fourth National Radio Conference, Washington, November 9-11, 1925, was presented and accepted with a vote of appreciation to Dr. Kennelly for his services.

Other matters of importance were discussed, reference to which may be found in this and future issues of the JOURNAL.

Standards of the A. I. E. E.

At the meeting of the Board of Directors held December 11, 1925, the following Sections of Standards, as recommended by the Standards Committee, were adopted as Institute Standards.

No. 9—Standards for Induction Motors and Induction Machines in General.

No. 30—Standards for Wires and Cables.

No. 9 was referred to the Sectional Committee on Rating of Electrical Machinery, for consideration and report to the sponsor. No. 30 was referred to the Sectional Committee on Insulated Wires and Cables, for consideration and report to the sponsor, and then to be referred to the American Engineering Standards Committee for approval as an American Standard.

The following three Sections of the A. I. E. E. Standards were referred to the Sectional Committee on Rating of Electrical Machinery.

No. 5—Standards for Direct-Current Generators and Motors and Direct-Current Commutator Machines in General.

No. 7—Standards for Alternators, Synchronous Motors and Synchronous Machines in General.

No. 10—Standards for Direct-Current and Alternating-Current Fractional Horse Power Motors.

The following resolutions were adopted:

RESOLVED

THAT in support of the plans and purposes of the A. E. S. C. in establishing American Standards, and recognizing the value and necessity of cooperative procedure in the field of electrical standardization, the Board of Directors of the American Institute of Electrical Engineers recommends to the A. E. S. C. that the A. E. S. C. set up an Electrical Advisory Committee of the A. E. S. C. constituted of representatives of at least the major interested groups, to advise the Main Committee on all questions relating to Electrical standards and to serve as a general coordinating committee in the electrical field within the scope of the Constitution, By-Laws and Rules of Procedure of the A. E. S. C.

RESOLVED FURTHER

THAT it is recommended that this Advisory Committee should have such constitution and functions as to be sufficiently elastic to permit the appointment of Special Committees of particularly qualified experts to pass upon specific questions in case any interested parties so requesting should submit to the A. E. S. C. reasonable evidence of the desirability of such action.

Corrections in Standards Pamphlets

Section 1. General Principles Upon Which Temperature Limits are Based in the Rating of Electrical Machinery and Apparatus.

In the reprint (September 1925) of Section 1 of the A. I. E. E. Standards the following fundamental statement should appear just below the title on page 5:

"THESE ARE NOT RULES FOR RATING OR TESTING"

"The limits of temperature and temperature rise given in the pamphlet are not limits for the rating or testing of electrical machinery. The pamphlet deals with the general considerations upon which rating limits are based. It is the introductory chapter to the Standards of the A. I. E. E."

Attention is also called to the corrections as noted on page 1359 of the December JOURNAL. Correct copies of both Sections 1 and 10 can be obtained by returning the incomplete pamphlets to H. E. Farrer, Secretary, Standards Committee, A. I. E. E., 33 West 39th St., New York, N. Y.

American Roadbuilders' Association in Convention January 11-14.

The Annual Convention and Road Show of the American Road Builders' Association will be held in Chicago, January 11-15, 1926. Sessions will be held for the discussion of varying problems in connection with traffic regulation, highway design and construction, with an innovation this year of a division of these meetings into two sections—one for the investigation of traffic and engineering problems contingent to the cause, and the other for points of interest on the side of construction. Men nationally representative for each subject on the program will address the meetings and these addresses will be followed by open, general discussion.

Dr. Parke Rexford Kolbe New President of Polytechnic Institute

An event of interest to engineers and chemists generally will take place at the Academy of Music, Brooklyn, N. Y., on January 13th, 1926, when Doctor Parke Rexford Kolbe will be installed as the new president of the Polytechnic Institute. Doctor Charles Alexander Richmond, president of Union College, will deliver the principal address of the evening; the presentation of the charter, seal and keys will be made by Charles E. Potts, of

the class of 1892, now chairman of the Board of Trustees of the Polytechnic Institute. Other speakers of the evening will be Doctor William H. Nichols, chairman of the Board of the General Chemical Company, and for many years chairman of the Corporation of the Polytechnic Institute; Doctor George S. Collins, senior member of the faculty, and Bancroft Gherardi, chief engineer of the American Telephone and Telegraph Company. Official delegates from colleges, universities and societies have been invited to attend and acceptances received indicate an attendance of a noteworthy number of prominent men from all parts of the country; among them Robert Lincoln Kelley, executive secretary of the Association of American Colleges; George B. Pegram, president of the Society for the Promotion of Engineering Education; W. E. Wickenden, director of Investigation for the Society for the Promotion of Engineering Education; H. Foster Bain, secretary of the American Institute of Mining and Metallurgical Engineers; Robert Ridgway, American Society of Civil Engineers; Elmer E. Brown, Chancellor, New York University; Charles C. Mierow, president of the Colorado College; General James G. Harbord, Kansas State Agricultural College, Col. R. C. Langdon, West Point; Arthur M. Greene, Jr., Engineering Foundation; Palmer C. Ricketts, Rensselaer Polytechnic Institute, and Allen Hazen, University of New Hampshire. A reception for the official delegates will be held at the conclusion of the academic exercises.

ENGINEERING FOUNDATION

PROFESSOR MARX SUCCEEDS PROFESSOR DERLETH, Jr.

Charles David Marx, professor emeritus of civil engineering, Leland Stanford, Jr., University, has been elected chairman of the Engineering Foundation Committee in charge of the Arch Dam Investigation. He succeeds Professor Derleth, Jr., of the University of California, who relinquishes the chairmanship because of ill health, but continues a member of the working committee.

The Southern California Edison Company is furnishing the services of its chief construction engineer, H. W. Dennis to be in charge of the building of the test dam, and also the services of other members of its organization essential to the accomplishment of this undertaking. Use of the property for the erection of the dam is contributed by the U. S. Department of Agriculture: The Portland Cement Association is also cooperating and Doctor J. A. Mathews, vice-president and metallurgist of the Crucible Steel Company of America is producing special metal for some of the instruments.

The Engineering Foundation contributes funds and services for the general purpose of the Committee, but unfortunately its resources will not yet permit it to do more. It invites all others interested to cooperate in providing the remainder of the $100,000 necessary to the completion of the dam.

AMERICAN ENGINEERING COUNCIL

AN APPEAL TO AID BILL FOR PROVIDING ADEQUATE SALARIES FOR FEDERAL JUDGES

BY EDWIN J. PRINDLE.

Chairman, Patents Committee

Americans having to do with engineering, science or the industries are pretty generally aware of the tremendous importance of keeping our patent system operating in a helpful and efficient manner. They realize that that system has been of primary importance in enabling our country to attain the foremost position among the nations in inventing, manufacturing and agriculture. When the Patent Office was going to pieces because of salaries insufficient to induce trained Patent Office Examiners to stay in the service, after a long and arduous campaign, the technical and scientific men and the manufacturers succeeded in sufficiently raising the Patent Office salaries to stem the tide of resignations, with the result that the Patent Office was saved from disintegration and has now made substantial progress toward an efficient condition.

But the granting of patents is only one branch of the operation of the patent system. The other branch is the adjudication of patents and their enforcement in proper cases. This latter function is performed exclusively by the federal courts and the efficient operation of those courts is of as much importance to the patent system as that of the Patent Office. The rise in the cost of living, and the depreciation of the purchasing power of the dollar have placed those in courts in a position where their efficiency is being impaired by causing many excellent judges to resign and by disturbing that peace of mind without which the best work is not likely to be done. Many of the judges are restive and waiting to see whether relief will not be given them, feeling that they will be forced to leave the bench if the present condition continues. Distress of the judges is particularly keen in the larger cities where the cost of living is highest. Here also it is more unjust that they should be asked to work for totally inadequate salaries because the compensation which they could receive in the private practise of law is correspondingly greater. The federal courts have jurisdiction over a wide variety of subjects—much wider than that of the courts of any of the States—so that the position is one of large responsibility, and requiring a high order of ability. Yet their salaries are so low that they are unable to live as befitting their station and the high dignity of their office, and to educate their children. They may not practise law, and have practically no opportunities for earning, outside of their salaries.

These conditions are probably more important to the welfare of our patent system than to any other branch of the law, because almost without exception, the federal judges when appointed, have had no contact whatever with patent law. It takes years of education and experience in trying and listening to the argument, and in deciding patent cases, to make a competent patent judge under these circumstances. When a federal judge who is efficient in patent law resigns, the process of education has to be gone through with by his successor, and the result necessarily is in such cases that the average ability brought to the decision of patent cases over a series of years is low. A few unwise decisions would cost not only the parties, but the country, many times the difference between present salaries and adequate ones.

The United States district judges receive but $7500 per annum and United States circuit judges only $8500. Comparison with the salaries paid in the State courts shows the gross unfairness of these salaries.

In New York City the Supreme Court judges receive $17,500, and the question is being considered of raising that salary. The judges of the New York Court of Appeals in Albany receive $13,750.

In New Jersey the judges of the Supreme Court receive $18,000.
In Pennsylvania they receive $17,500.
In Illinois they receive $15,000.
In Massachusetts they receive $12,000.
In Michigan they receive $10,000.

A bill having the approval of the federal judges has been introduced into Congress, known as the Reed Bill, which provides salaries for the circuit judges of $15,000 for the Second Circuit, comprising New York and Vermont; $14,000. for the next most populous circuits—Third, Seventh, Eighth and Ninth; and $13,000 for the remaining of the nine circuits.

The Bill provides salaries for the United States District judges of $10,000 with the provision that if the population in a district exceeds 2,000,000 the salaries shall be increased $500 for each 100,000 population in excess of that sum up to within $1000

of the circuit judges' salary. If the differential in favor of the salaries in the more populous districts should not be enacted, then the salaries for the district judges in general should be correspondingly raised.

While our federal judicial system is one of the three great branches of our government and is co-equal in importance with the legislature and the executive, yet its cost is truly insignificant. There are only 191 federal judges, and the cost per capita is now but one and one-half cents.

No matter how conscientious a judge may be, it is impossible for him to have as high an average of clear, penetrating thought in deciding the many intricate and important questions which come before him if his living and that of his family are inadequately provided for, as if his mind is reasonably free from financial care. The loss to the public through avoidable mistakes of failure to think clear through a problem under these conditions, must be vastly greater than the cost of proper salaries.

As Ex-Judge Edwin L. Garvin of Brooklyn has said:

> "The present salaries paid to United States judges are a disgrace to the American people."

Judge Garvin has just left the Federal Bench, being forced to do so by inability to live on his salary and the absolute impossibility of giving a college education to either of his children. Many of the federal judges are eking out their salaries by using the savings which they had provided for their old age. The American Engineering Council has adopted vigorous resolutions favoring the increase of the federal judiciary salaries, and last winter appeared, by Mr. L. W. Wallace, its Executive Secretary, the Chairman of its Patents Committee, and other representatives, before the Committees of Congress in favor of bills for that purpose. These efforts will be continued and reinforced at the present session of Congress.

Fair play and simple justice should make every American citizen interested in correcting this unjust and unwise condition. Every man and concern who is at all interested in patents and in preserving our patent system in an efficient condition should express himself to his Senator and Representatives as being strongly in favor of immediately passing the Reed Bill or some other bill for raising the salaries at least as high as that bill.

Let us be as effective in aiding the federal judges as we were in aiding the Patent Office. That can be done if every man will do his duty.

Industrial Cooperation With the War Department

Hearty endorsement of the War Department in its program for industrial preparedness and insurance against war was represented by the large audience which gathered in the Engineering Societies Building, New York, on the evening of December 4, at a meeting held under the auspices of the New York Sections of the A. I. E. E., A. S. C. E., A. I. M. E., A. S. M. E., American Chemical Society and Society of Automotive Engineers, and the Army Ordnance Association. Honorable Elbert H. Gary presided and the speakers of the evening were Dwight F. Davis, Secretary of War; Hanford MacNider, Assistant Secretary of War; General James G. Harbord, president of the Radio Corporation of America, and Major-General Charles P. Summerall, Commander of the Second Corps Area, U. S. Army. A telegram of commendation from President Coolidge also was read. Prior to the addresses, the colors of the 24th Regiment of Engineers were transferred, by an impressive ceremony, to the custody of the United Engineering Societies.

Secretary Davis first spoke of the many constructive peacetime accomplishments of the Army, including its activities in standardization, communication, navigation, power development, medicine, agriculture, mail, merchandising and aviation.

He then outlined the plans and the necessities for industrial preparedness for national defense. He said, in part, that the saving of time in swift and effective mobilization is the essence of all plans. Industrial preparedness means that demands of finance, power, labor, transportation and materials be intelligently analyzed and properly coordinated, that all resources may be marshalled against aggression. The combination of a weak and wealthy nation has never existed for any length of time. If present plans can render America safe for peace for one generation only they will accomplish more than any other plans in our history.

Two pictures of industry stand out in the planning: The one is the picture of industry as it operates in time of peace; the other, the picture as it looks in war. Industrial preparedness has as its purpose the planning of the transition from one picture to the other, with a minimum of dislocation and confusion both before and after war. Competent bodies have studied and are studying the general problems, with the cooperation of business and industrial concerns and of individuals, and courses of action are being formulated.

In general industrial preparedness is the contribution of business to the national peace. It is preparedness against war, not for war. But if war comes it will be a potent factor in winning peace through victory. Equality of obligation, mutuality of responsibility, the common defense of all by all is the democratic doctrine of a free republic. This is the spirit of industrial preparedness.

Assistant-Secretary MacNider emphasized the fact that for each combat soldier there should be seventeen people backing him up with material. With the help of experts and business executives plans have been formulated for swift mobilization. The supply organization must be built so that it can in a moment be stretched to a hundred times its peace-time size and function effectively. The nation's best insurance against war is not a great army but an expert nucleous.

General Harbord emphasized the need of sustaining interest and support for the work of national defense of which industrial preparedness is one part. To bring out the advantage of preparedness, he stated that if the present plan and organization had been in effect prior to the World War, besides greatly decreasing our losses in killed and wounded, for every hour by which the war was shortened one million dollars would have been saved.

Major-General Summerall, in the name of the Army, acknowledged all that industry is doing for the welfare of the military establishment and the country, and said that these efforts hearten and encourage that establishment beyond measure.

ADDRESS OF W. L. SAUNDERS, ACCEPTING THE 24TH ENGINEERS COLORS

Engineering Auditorium, December 4, 1925

Colonel Whitlock and men of the 24th Engineers:

On behalf of the Trustees of United Engineering Society I accept the custody of these colors of the 24th Engineers. They shall be carefully installed and exhibited in the halls of this building, there to remain as a permanent memorial.

Yours was the first regiment of its kind to be organized in the Army of the United States. Never before had the value and aid of the engineers in war been so fully recognized. You built and maintained shops, cement block plants, railways, pumping stations, lighting plants, buildings, hospitals, schools, camps, stables and many other things so important in modern warfare. To the men in the trenches you were what the laboratory is to the chemist. Through such work as you did the world war was brought to an end.

And as future generations look upon these colors, they shall see in them not a cold monument of stone raised to a gallant warrier, whose example one might seek to follow, but a living reminder that strength in war is no longer a human, but a material thing; that through machinery, industry and engineering a nation fully prepared in peace is likewise prepared for and insured against war.

Fuel and Power Meeting Held in Boston

Power problems in industrial plants were discussed at a meeting held in Boston, December 10 and 11, by the Affiliated Technical Societies of Boston of which the A. I. E. E. Section is a member. The papers presented were *Sources and Utilization of Coal*, by F. H. Daniels, Sanford-Riley Stoker Company; *Supply and Utilization of Fuel Oil*, by E. H. Peabody, Peabody Engineering Corp.; *Diesel Engines for New England Power Plants*, by J. F. Hecking, Worthington Pump and Machinery Corp.; *Possibilities of Obtaining Power from Public-Service Corporations*, by L. R. Nash, Stone & Webster, Inc.; *Power for Textile Mills*, by C. T. Main, Consulting Engineer; *Power for the Paper Industry*, by J. A. Warren, S. D. Warren Company; *The Utilization of Power in the Typical New England Plant*, by K. D. Hamilton, Geo. E. Keith Company; *The Advantages and Disadvantages of High-Pressure Steam in Industrial Plants*, by Joseph Pope, Stone & Webster, Inc.; *Utilization of Extraction Steam*, by E. A. Dickinson, General Electric Company; *The Supply of Industrial Power*, by W. H. Larkin, Jr., U.S. Rubber Company; *The Coal Situation*, by E. C. Hultman, Chairman of Special Commission (Mass.) on the Necessaries of Life; *Household Heating*, by H. R. Linn, American Radiator Company.

Sterling Fellowship for Research at Yale

The Sterling Fellowship has been established by a gift of one million dollars from the John W. Sterling Estate, "to stimulate scholarship and advanced research in fields of knowledge." While a Yale University fellowship, this is open to all approved colleges and universities both here and abroad,—men and women —whether graduate students, instructors or professors who desire to carry on studies and research under the direction of the Graduate Faculty of Yale University in affiliation therewith. Applications should be addressed to the Dean of the Graduate School, Yale University, New Haven, Connecticut, on blanks supplied by him. Junior prior to March 1 and Senior Fellowships by April 1.

Penn State Branch Holds Electrical Show

On November 7, the annual Alumni Homecoming Day, the Student Branch at the Pennsylvania State College presented an electrical show in the laboratories of the two Electrical Engineering Buildings. The exhibits which were designed and prepared by the members of the Branch proved of great interest to the thousands who visited the show.

The exhibits, of an educational nature, showed the work carried out in the Electrical Engineering Department of the College. Other exhibits traced the historical development of common electrical devices. Special lighting exhibits were featured at the night session. Numerous trick features constituted a less serious part of the show.

PERSONAL MENTION

G. W. Quentin has resigned from the American Blower Company in Pittsburgh to accept the position of promotion manager for the *Electrical World*.

F. L. Gilman has been elected Treasurer of the Western Electric Company to take effect January 1, 1926, and thereafter will be located at 195 Broadway.

Morris Keiser, formerly with the National Bureau of Standards, has joined the Research Department of the Marland Refining Company as Associate Electrical Engineer.

Harold J. McCreary, Inspection Methods Engineer of the Western Electric Company, has accepted a position as research engineer with the Automatic Electric Company of Chicago.

James R. Cravath, President of the Pioneer Electric Company of Richmond, Calif., has opened an office in the Call Building, San Francisco, as a consulting electrical and illuminating engineer.

Harry A. Yoe has resigned from the engineering department of the New York Central Railroad where he has been employed for ten years and has entered the firm of Schultze & Weaver of New York City.

Clifford G. Hillier, formerly manager of the Merchandising Sales Department of the Westinghouse Electric & Manufacturing Company, in their Boston office, has been appointed manager of the Receiver Section of the Radio Department of that Company, with headquarters in New York City.

Dr. E. R. Berry, assistant director of the Thomson Research Laboratory of the General Electric Company of Lynn, Mass., has been awarded the Grasselli Medal by the American Section of the Society of Chemical Industry, in honor of the paper presented by him describing a new achievement in applied chemistry.

Samuel W. Beach, Chief Radioman, U. S. S. Nevada, has recently written a book entitled, "The Great Cruise of 1925"—a history of the trip made by the United States Fleet to Australia, New Zealand and South Sea ports. It also contains speeches made by the Premiers and Governors-General of Australia and New Zealand upon the occasion of the fleet's visit to their respective countries.

Addresses Wanted

A list of names of members whose mail has been returned by the Postal Authorities is given below, together with the addresses as they now appear on the Institute records. Any member knowing the present address of any of these members is requested to communicate with the Secretary at 33 West 39th St., New York, N. Y.

All members are urged to notify the Institute Headquarters promptly of any change in mailing or business address, thus relieving the member of needless annoyance and also assuring the prompt delivery of Institute mail, the accuracy of our mailing records, and the elimination of unnecessary expense for postage and clerical work.

1.—Ezra Adelsberger, 1912 Cold Spring Ave., Milwaukee, Wis.
2.—F. E. Bell, U. G. I. Contracting Co., Box 371, Sioux City, Iowa.
3.—Geo. B. Coleman, P. O. Box 322, Dayton, Ohio.
4.—T. L. Davenport, 2530 May St., Cincinnati, Ohio.
5.—George E. Haines, 3538 W. Monroe St., Chicago, Ill.
6.—S. Larios, 143 Fourth St., Milwaukee, Wis.
7.—Willis E. Osborne, 312 West 4th St., Erie, Pa.
8.—Mary Shimanovsky, 24 Mt. Morris Park W, New York, N. Y.

Obituary

George I. Brown, an Associate of the Institute since 1908, died on November 1st, 1925. Mr. Brown was a Canadian by birth and received his education under private tutoring and at the University of Toronto, being employed by the Canadian Government during the years 1879 to 1892. Mr. Brown resided in this country for many years, in 1915 opening an office as consulting engineer in Red Bank, N. J.

David C. Rankin, Managing Director of the Commonwealth Power Equipment Company of Melbourne, Australia, died in that city after an illness of two years. Mr. Rankin was a native of Melbourne, being a graduate of Melbourne University, and coming to this country in 1919. He was in the employ of the Guarantee Battery Company of San Francisco as automotive instructor and the Ballantine Electrical Company of Chicago as plant superintendent and general manager, returning to Australia in July, 1923.

Allen A. Tirrell, inventor and consulting engineer of the

Westinghouse Electric & Manufacturing Company died recently. Mr. Tirrell was the inventor of the voltage regulator which bears his name, being employed for some years by the General Electric Company as a designing engineer—later going into business for himself as mechanical and electrical engineer in Pittsburgh.

George Harry Wirth, Associate of the Institute for the past five years, died at his home in Collingdale, Pennsylvania on November 6th. Mr. Wirth received his engineering education at Drexel Institute in Philadelphia; during the World War he served as a commissioned pilot instructor in the air Service of the United States Army. He was afterwards in the employ of Stone & Webster, in Philadelphia, later with the Right and Left Tool Holder Company and with the Edw. G. Budd Manufacturing Company as operator in charge of High Voltage Substations.

Engineering Societies Library

The library is a cooperative activity of the American Institute of Electrical Engineers, the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers and the American Society of Mechanical Engineers. It is administered for these Founder Societies by the United Engineering Society, as a public reference library of engineering and the allied sciences. It contains 150,000 volumes and pamphlets and receives currently most of the important periodicals in its field. It is housed in the Engineering Societies Building, 29 West Thirty-ninth St., New York.

In order to place the resources of the Library at the disposal of those unable to visit it in person, the Library is prepared to furnish lists of references to engineering subjects, copies or translations of articles, and similar assistance. Charges sufficient to cover the cost of this work are made.

The Library maintains a collection of modern technical books which may be rented by members residing in North America. A rental of five cents a day, plus transportation, is charged.

The Director of the Library will gladly give information concerning charges for the various kinds of service to those interested. In asking for information, letters should be made as definite as possible, so that the investigator may understand clearly what is desired.

The library is open from 9 a. m. to 10 p. m. on all week days except holidays throughout the year except during July and August when the hours are 9 a. m. to 5 p. m.

BOOK NOTICES (Nov. 1-30, 1925)

Unless otherwise specified, books in this list have been presented by the publishers. The Society does not assume responsibility for any statement made; these are taken from the preface or the text of the book.

All books listed may be consulted in the Engineering Societies Library.

DYNAMIK, 2; DYNAMIK VON KÖRPERSYSTEMEN.

By Wilhelm Müller. Ber. u. Lpz., Walter de Gruyter & Co., 1925. 137 pp., 6 x 4 in., cloth. 1.25 mk.

Devoted to the methods for mathematically investigating the motion of structures composed of rigid elements. An attempt is made to condense the development of the subject as much as possible and to arrange the whole systematically. The analytic methods used are grouped in general around d'Alembert's principle.

ELEKTROMASCHINENBAU.

By P. B. Arthur Linker. Ber., Julius Springer, 1925. 304 pp., diagrs., 9 x 6 in., boards. 24-gm.

A textbook on the design of continuous-current dynamos and motors, transformers, induction motors, synchronous dynamos and motors, converters and alternating-current commutator motors. The book follows the course given in the Hannover Technical High School.

The author shows how the design of electrical machinery may be based on the intelligent use of the elements and basic laws of theoretical electricity, and how it may be used also to deepen by use the student's knowledge of theory. At the same time, many devices to lessen the purely clerical items of design are shown.

FOUNDATIONS OF BRIDGES AND BUILDINGS.

By Henry S. Jacoby and Roland P. Davis. N. Y., McGraw-Hill Book Co., 1925. 665 pp., illus., diagrs., 9 x 6 in., cloth. $6.00.

Treats of piles and pile driving, cofferdams, caissons, piers, abutments, spread foundations and underpinning. Intended to present American practice on the entire subject of foundations in a systematic manner. Includes a useful, classified bibliography of selected articles.

The new edition has been revised and amplified.

FOUR-FIGURE MATHEMATICAL TABLES.

By G. W. C. Kaye and T. H. Laby. Lond., & N. Y., Longmans, Green & Co., 1925. 26 pp., 10 x 6 in., paper. $.40.

A convenient collection of the mathematical functions usually tabulated in four-figure tables, printed in clear type. Logarithms, anti-logarithms, reciprocals, squares, natural and logarithmic sines, cosines and tangents, degrees to radians, powers, roots and reciprocals are included.

HISTORY OF ARITHMETIC.

By Louis Charles Karpinski. Chic. & N. Y., Rand McNally & Co., 1925. 200 pp., illus., facsims., 8 x 5 in., cloth. $2.00.

A brief account, intended primarily for teachers of arithmetic in elementary schools. Gives particular attention to the material of arithmetic which is still taught in those schools. It also pays particular attention to early American textbooks and to the popular English treatises from which they were derived. Bibliographies accompany each chapter and there are many illustrations from early books.

INTERMEDIATE LIGHT.

By R. A. Houstoun. Lond. & N. Y., Longmans, Green & Co., 1925, 228 pp., illus., diagrs., 8 x 5 in., cloth. $1.75.

A brief elementary textbook intended for use by students in secondary schools and the first years of college.

MAKING, SHAPING AND TREATING OF STEEL. 4th edition.

By J. M. Camp and C. B. Francis. Pittsburgh, Pa., Carnegie Steel Co., 1925. 1142 pp., illus., diagrs., tables, 8 x 5 in., fabrikoid. $7.50. [Payment should accompany order. Money orders and checks to be made payable to Carnegie Steel Co. Orders and inquiries should be addressed to Carnegie Steel Co., Bureau of Technical Instruction, Carnegie Bldg., Pittsburgh, Pa.]

This book is intended primarily for use as a text-book in the schools conducted by constituent companies of the United States Steel Corporation for employees without a technical education. It is also admirably adapted to the needs of every one, wishing an accurate account of standard practice in the American steel and iron industry.

Beginning with a survey of those principles of physics and chemistry which are useful to the metallurgist, the authors take up refractories, iron ores, fuels, fluxes, describing their varieties, properties and uses. The manufacture of pig iron, wrought iron and steel are then discussed. Section two is devoted to the shaping of steel by rolling and forging. Section three treats of the constitution, heat treatment and composition of steel. Section four describes the manufacture of wire, sheets, pipe and tubes.

No other book approaches this in its fulness of detail on current practise in American iron and steel works. It is a complete account of the industry, from the ore to the semi-finished product, prepared by men in intimate contact with current practice.

MECHANICAL INVESTIGATIONS OF LEONARDO DA VINCI.

By Ivor B. Hart. Chic., Open Court Pub. Co., 1925. 240 pp., illus., facsims., port., 9 x 6 in., cloth. $4.00.

The author's primary purpose was to make a detailed study of the nature and value of Leonardo's contribution to the study of aeronautics, but as the study of flight is linked with that of mechanics, the whole field of his work in mechanics has been surveyed.

After an introductory chapter on the characteristics of

Leonardo's manuscripts, there is a discussion of the state of mechanical science in the fifteenth century, of the scientific influences that bore upon Leonardo and of the sources of information available to him. This is followed by an account of his work in mechanics and as a pioneer of aviation. The book concludes with a complete translation of his Codex on the Flight of Birds and other Matters from the manuscript in the Library of Turin.

MECHANISM OF THE CAR.

By Arthur W. Judge. Lond., Chapman & Hall, 1925. (Motor manuals, v. 3.) 175 pp., illus., 8 x 5 in., cloth. 4s.

A non-technical exposition of the basic principles, illustrated by examples from current automobile practice. Covers the chassis, transmission, gears, etc. While adapted to use by owners and mechanics, it also will interest the engineer.

OIL ENGINE POWER PLANT HANDBOOK.

By Staff of Oil Engine Power. N. Y., Oil Engine Power, 1925. 192 pp., illus., diagrs., 11 x 8 in., fabrikoid. $3.00.

The work is a combination of catalog information on the products of various manufacturers of oil engines and accessories, with a series of articles by various engineers. These articles treat of such matters as lubrication, operation and maintenance, valve-setting, installation and similar topics, and are written from a practical viewpoint.

OSCILLOGRAPHS. . . .

By J. T. Irwin. N. Y., Isaac Pitman & Sons, 1925. 164 pp., illus., diagrs., 7 x 5 in., cloth. $2.25.

After a chapter on the fundamental principles involved, the author describes the various types of oscillographs and the methods of damping. Much space is given to the cathode-ray oscillograph. The book is apparently the first in English devoted to the subject and is, the author remarks, to a great extent original.

PHOTO-ELECTRICITY. . . .

By H. Stanley Allen. 2d edition. Lond. & N. Y., Longmans, Green & Co., 1925. (Monographs on physics). 320 pp., 9 x 6 in., cloth. $6.50.

A very complete exposition of our theoretical knowledge of photo-electric phenomena and of the practical applications of photo-electric cells. The new edition incorporates the results of the investigations during the past decade and includes a valuable bibliography of all the relevant papers published between 1913 and 1924.

PRINCIPLES OF ELECTRIC POWER TRANSMISSION AND DISTRIBUTION.

By L. F. Woodruff. N. Y., John Wiley & Sons, 1925. 340 pp., illus., diagrs., tables, 9 x 6 in., cloth. $4.00.

A work based on instruction given to senior and graduate students at the Massachusetts Institute of Technology. Its aim is to call attention to the fundamental scientific principles involved in power transmission and the methods by which they are made applicable to practical engineering problems; and at the same time to impart as much information as is feasible about present practise in electric power transmission.

PROTEUS, OR THE FUTURE OF INTELLIGENCE.

By Vernon Lee. N. Y., E. P. Dutton & Co., 1925. (To-day and to-morrow series.) 63 pp., 6 x 4 in., cloth. $1.00.

In this very interesting little volume Vernon Lee discusses intelligence; what it is, when it originated, and how it influences us in the realms of art, religion, morals and economics and in our personal lives and outlooks.

THEORY OF MEASUREMENTS.

By Lucius Tuttle and John Satterly. Lond. & N. Y., Longmans, Green & Co., 1925. 333 pp., diagrs., 9 x 6 in., cloth. $4.50.

This textbook is intended for use in connection with courses in physics or mathematics. It emphasizes general considerations of measurement, theory of errors, general methods of procedure, quantitative accuracy, adjustment of observations, and similar topics that are usually merely mentioned in a laboratory manual, but that need laboratory work and drill as much as measurements of individual quantities. It is also adapted for use as a reference book.

The work represents a course given in the University of Toronto.

TREATISE ON THE LAW OF PUBLIC UTILITIES.

By Oscar L. Pond. 3rd edition. Indianapolis, Bobbs-Merrill Co., 1925. 1065 pp., 10 x 7 in., buckram. $10.00.

An endeavor to give a full, impartial exposition of the law of municipal public utilities. The book is based on the decisions of the courts and the various commissions, so that it is authoritative and practical. The new edition contains an extended study of motor vehicle transportation and a chapter on the subject of appeals.

Past Section and Branch Meetings

SECTION MEETINGS

Akron

Frogleg Windings for Multipolar D-C. Generators and Motors, by G. M. Albrecht, Allis Chalmers Co. A dinner preceded the lecture. November 20. Attendance 54.

Boston

Business Meeting. November 23. Attendance 8.

Chicago

Rectifiers, by L. T. Robinson, General Electric Co. Joint with Western Society of Engineers. November 23. Attendance 260.

Cincinnati

Transmission Problems, by C. L. Fortescue, Westinghouse Elec. & Mfg. Co. An illustrated lecture on the "Klydonograph" was also given. November 10. Attendance 142.

Connecticut

Distribution at Increased Voltages, by J. E. King, Connecticut Light and Power Co. December 9. Attendance 125.

Cleveland

Inspection trip to the plant of the Otis Steel Company. October 22. Attendance 300.

Denver

Some Epoch-Making Scientific Advances within the Last One Hundred Years, by B. F. Howard, The Mountain States Telephone and Telegraph Co. November 20. Attendance 33.

Erie

The Metric System, by Howard Richard, Secretary of the Metric Association. A buffet luncheon was served. November 17. Attendance 65.

Fort Wayne

Transformers and Reactors in Radio, by R. H. Chadwick, General Electric Co. Motion pictures on the action of radio receiving tubes were shown. November 12. Attendance 40.

Ithaca

The Power System of Alabama, by F. G. Switzer and J. G. Tarboux. November 20. Attendance 50.

Lehigh Valley

Automatic Stations and Their Remote Supervision, by Chester Lichtenberg, General Electric Co. October 30. Attendance 50.

Power—Electrical and Personal, by Farley Osgood, Consulting engineer and Past-President of the A. I. E. E.;

Developments in Control of Mine Equipment, by H. D. James, Westinghouse Electric & Mfg. Co., and

Business Engineering, by J. H. Pierce, Buck Run Coal Company. The three above addresses were given November 13 and an inspection trip was made to the Lansford Coal Company and the Lehigh Coal and Navigation Company November 14. Attendance 200.

Los Angeles

Automatic Substations and Power Conversion for Railway Purposes, by L. J. Turley, Los Angeles Railway Co., December 1. Attendance 118.

Lynn

Dream Pictures, by Branson DeCou. This was in the form of a musical travelog, illustrated with masterpieces of art and photography. November 23. Attendance 580.

Industrial Heating by Electricity, by N. R. Stansel, General Electric Co. Illustrated with slides. December 2. Attendance 100.

Madison

Natural Electricity and Lightning Protection, J. Slepian, Westinghouse Elec. & Mfg. Co. November 27. Attendance 80.

Mexico

Substations, by L. M. Speirs, Mexican Light & Power Co. November 5. Attendance 34.

Milwaukee

The History of Cooperation Among Engineers, by W. M. White, Allis Chalmers Mfg. Co.

Activities of A. I. E. E. in Great Lakes District, by Professor Edward Bennett, University of Wisconsin. A film, entitled "Milwaukee Electrically" was shown. Dinner meeting. November 23. Attendance 75.

Minnesota

Some Contemporary Advances in Radio Communication, by Professor C. M. Jansky, University of Minnesota. November 30. Attendance 100.

Niagara Frontier

Radio Development, by C. W. Horn, Westinghouse Electric & Mfg. Co. November 6. Attendance 35.

Some Fundamental Properties of the Electron, by Professor V. Karapetoff, Cornell University. December 7. Attendance 123.

Pittsfield

Certain Researches and Hobbies, by Dr. W. R. Whitney, General Electric Co. November 17. Attendance 280.

Round-table discussion on fundamental considerations of power limits of transmission systems with special reference to stability. Mr. R. E. Doherty, General Electric Co., led the discussion by abstracting his paper "Fundamental Considerations of Power Limits of Transmission Systems." December 8. Attendance 60.

Portland

Public-Service Management, by F. T. Griffith, Portland Electric Power Co. A motion picture, entitled "Modern Pioneers" was shown. November 18. Attendance 165.

Providence

The Quest of the Unknown, by Professor H. B. Smith, Worcester Polytechnic Institute. December 2. Attendance 50.

Rochester

Automatic Train Control. This illustrated lecture was written by W. H. Reichard, General Railway Signal Co., but presented by one of his assistants. November 6. Attendance 50.

Saskatchewan

Advances of Physical Science from the Electrical Viewpoint, by Dr. E. L. Harrington, University of Saskatchewan. November 27. Attendance 65.

Schenectady

Smoker. October 23. Attendance 350.

The Quest of the Unknown, by Professor H. B. Smith, Worcester Polytechnic Institute. Illustrated with slides. November 13. Attendance 310.

Springfield

Electric Propulsion of Ships, by W. E. Thau, Westinghouse Elec. & Mfg. Co. Illustrated with slides. November 23. Attendance 56.

Toledo

Police, Fire and Traffic Signal Systems, by Tyler Green, Chief City Electrician. After the lecture an inspection trip to an engine house was made. November 18. Attendance 35.

Toronto

Electric Steam Generators, by C. E. Sisson, Canadian General Electric Co. November 13. Attendance 63.

Watthour Meters, Demand Meters and Kv-a. Meters, by E. G. Ratz, Canadian Westinghouse Co. Illustrated with slides, and

Recent Developments in Relays, by L. N. Crichton, Westinghouse Elec. & Mfg. Co. November 27. Attendance 100.

Utah

Switchboards and Switches, by S. W. Mauger, General Electric Co. Illustrated with slides and moving pictures. October 21. Attendance 44.

Carrier-Current Communication, by R. E. Pierce, Utah Power & Light Co., and

Temperature and Motor Endurance, by Leo Brandenberger, Electrical Engineer. Illustrated with moving picture. December 2. Attendance 46.

Vancouver

Radio, by Dr. H. Vickers, University of British Columbia. Illustrated with slides. December 1. Attendance 61.

Washington

Municipal Electrical Regulation, by A. R. Small, National Fire Protection Association. December 8. Attendance 112.

Worcester

Transmission of Pictures over Wires, by R. D. Parker, American Telephone and Telegraph Co. Illustrated with slides. November 19. Attendance 75.

BRANCH MEETINGS

Alabama Polytechnic Institute

A motion picture, entitled "White Coal," was shown. November 18. Attendance 38.

The Tunnel under the Hudson River, by Mr. Earnest;

The Development of the Steam Locomotive, by Mr. Stain. Mr. Allen gave a talk on his work with the Westinghouse Company. Joint meeting with A. S. M. E. December 2. Attendance 21.

Armour Institute of Technology

Smoker. November 18. Attendance 72.

Wired Wireless, by R. U. Hagen, Illinois Bell Telephone Co. Illustrated. December 3. Attendance 59.

University of Alabama

Talks on membership in the A. I. E. E. were given by F. R. Maxwell, Jr., C. E. Rankin and E. H. Pritchett. Moving pictures, entitled "Back of the Button (Electrical)" and "How Uneeda Biscuits Are Made," were shown. November 16. Attendance 14.

Brooklyn Polytechnic Institute

Radio Meters and Their Application, by Mr. Banks, Jewell Electric Instrument Co., and

Transmission of Motion Pictures by Radio, by Joseph Heller, student. November 24. Attendance 50.

Inspection trip to the new Swedish liner "Gripsholm." December 5. Attendance 50.

University of California

Business Meeting. The following officers were elected: Faculty Advisor, T. C. McFacland; Chairman, E. A. Fenander; Vice-Chairman, E. L. Ramer; Secretary, C. F. Dalziel; Treasurer, G. B. Kenline. November 24. Attendance 25.

University of Cincinnati

Miami Fort Power Plant, by J. R. Hartman, Columbia Gas and Electric Co. Illustrated with slides. November 12. Attendance 75.

Power Transmission, by Professor A. M. Wilson, University of Cincinnati. November 19. Attendance 70.

Clarkson College of Technology

A talk on his experiences while working with the General Electric Company was given by Edward Augustine. November 17. Attendance 21.

Clemson Agricultural College

Past, Present and Future of Industrial Accident Prevention, by J. A. Davis:

The Economics of Safety, by F. A. Burley;

Safety Work at the Plants of the Southern Manganese Corporation, and Federal Phosphorous Company, by F. J. Fishburne, and

Current Events, by J. R. Smith. November 5. Attendance 22.

University of Colorado

Officials of the Public Service Company from Denver and Boulder explained the Doherty Training Course offered by the Public Service Company for college graduates. After the meeting the visitors inspected the electrical engineering laboratories of the University of Colorado. November 18. Attendance 60.

Super Power, by H. M. Webber, student, and

Resuscitation from Electric Shocks, by Dr. Gillespie. Demonstrated. December 2. Attendance 55.

University of Denver

The Wave Propagation of High Frequency, by Stewart Ellis, and

A Year's Progress in Lighting, by Earl Reed. November 12. Attendance 15.

A New Departure in Electrical Education, by C. A. Conner, and

Electric Shovels, by O. C. Hawley. December 4. Attendance 21.

Drexel Institute

Recent Progress on the Delaware River Bridge, by Mr. Chase, A. S. C. E. Joint meeting with A. S. M. E. and A. S. C. E. December 4. Attendance 250.

University of Florida

The Development of Steam Turbines, by Mr. Carey, Western Electric Co., and

Heat Insulation, by Mr. Dean. Illustrated with slides. November 16. Attendance 20.

The Action and Development of the Bell Telephone, by Colonel R. L. Boyd, Southern Bell Telephone and Telegraph System. Illustrated with moving pictures. Joint meeting with Benton Engineering Society. December 7. Attendance 50.

Georgia School of Technology

Telephotography, by D. M. Therral, The Southern Bell Telephone Co. Illustrated with slides and photographs. November 24. Attendace 60.

University of Idaho

Experiences in Shops at Schenectady, by Professor Bailey. November 17. Attendance 15.

University of Iowa

Railless Electrical Vehicles, by F. A. Kulas, and

Manufacturing Insulated Copper Wire, by M. C. Little. November 18. Attendance 45.

The St. Lawrence Water Way, by R. H. Lird;

Rural Electrification, by E. F. Miller, and

Electric Locomotive Drives, by D. A. Shaw. November 25. Attendance 48.

Water, by N. C. Grover, United States Geological Survey. Joint meeting with A. S. M. E. and A. S. C. E. December 4. Attendance 53.

Alternating-Current Railways, by J. C. Risius, and

Wilson Dam, by G. Smith. December 9. Attendance 47.

Kansas State College

Summer Work with the Kansas Gas and Electric Company, by A. L. Brady. November 26. Attendance 76.

University of Kansas

Economics in Engineering, by Professor John Ise. December 3. Attendance 59.

Annual Banquet. December 10. Attendance 173.

University of Kentucky

Business Meeting. The following officers were elected: President, J. W. Weingartner; Secretary, C. E. Albert. October 7.

University of Maine

Business Meeting. The following officers were elected: Chairman, S. B. Coleman; Vice-Chairman, R. A. Parkman; Secretary, H. S. McPhee; Treasurer, R. M. Noyes. November 24. Attendance 9.

Massachusetts Institute of Technology

Uses of Vacuum Tubes, by O. M. Hovgaard, student. November 27. Attendance 21.

Inspection trip to plant of the General Electric Company at Lynn. December 2. Attendance 5.

Michigan State College

Business Meeting. November 17. Attendance 17.

A film, entitled "White Coal," was shown. November 24. Attendance 80.

School of Engineering of Milwaukee

Lightning Arresters, by R. N. Selleg, Westinghouse Electric & Mfg. Co. October 31. Attendance 56.

Business Meeting. The following officers were elected: Chairman, S. A. Moore; Vice-Chairman, Carl Herr; Secretary, B. J. Chromy; Treasurer, W. G. Peck. November 19. Attendance 25.

Missouri School of Mines and Metallurgy

Loud Speakers, by Dryden Hodges. December 4. Attendance 14.

University of Missouri

Talks were given by students on their Summer experiences working for various companies. October 19. Attendance 17.

Bell Telephone Laboratory of New York City, by Professor Grandy. A film on the manufacture of storage batteries was shown. November 2. Attendance 34.

Electrification of Railways—History and Development of Rapid Transit, by Professor Johnson. November 16. Attendance 21.

Montana State College

A moving picture, entitled "The King of the Rails." was shown. November 16. Attendance 162.

The Transmutation of Mercury into Gold. This lecture was read by B. A. Shaw, and

Hydrogen as a Cooling Medium for Electrical Machinery. Read by John Chamberlain. December 7. Attendance 159.

University of Nevada

Transformers, by W. C. Smith, General Electric Co. Illustrated with slides and a model transformer. November 18. Attendance 48.

College of the City of New York

Railway Signals, by James Wilson, student. November 19. Attendance 17.

Inspection trip to the Electrical Testing Laboratories. November 30. Attendance 14.

A report on the test of a 150-kw. alternator was given by Daniel Schneeweis and James Wilson. December 10. Attendance 13.

North Carolina State College

The Life and Work of the Late J. B Duke, and

Report of Committee on Production and Application of Light, by E. W. Chadwick. November 3. Attendance 36.

Methods of Resuscitation, by Captain Gordon, Red Cross Life Saving Corps. November 17. Attendance 45.

University of North Carolina

Hydrogen-Cooled Generators, by W. E. Wortman, student. November 19. Attendance 20.

University of North Dakota

Sightseeing in a Large Manufacturing Plant, by Professor D. R. Jenkins;

A New Theory of Light, by Elmer Johnston, student, and

Permalloy, by Helmer Gronhovd, student. November 16. Attendance 30.

The Vacuum Tube, by Karl Rudser, student, and

Muscle Shoals, by Merton Peterson, student. November 30. Attendance 15.

Northeastern University

Business Meeting. The following officers were elected: Chairman, F. W. Morley; Vice-Chairman, E. O. Alden; Assistant Secretary-Treasurer, L. C. Tyack. November 27. Attendance 21.

University of Notre Dame

Short-Wave Propagation, by Frank Castro, and

Heating as Your Job, by Mr. Strawbridge, Indiana and Michigan Elec. Co. November 2. Attendance 31.

A Comparison of Electrically Driven Centrifugal Oil Pumps with Steam-Driven Reciprocating Pumps, by M. B. Daly, and

The Milky Way, by Rev. Emil de Wulf. Illustrated. November 16. Attendance 26.

Ohio Northern University

Business Meeting. December 10. Attendance 15.

Ohio State University

Arc Welding, by E. K. Lincoln, Lincoln Electric Co. November 20. Attendance 180.

Oklahoma Agricultural and Mechanical College

Rural Electrification, by Earl Miller, student. Illustrated. November 18. Attendance 19.

University of Oklahoma

A Brake Test on a 0.000,001-H. p. Motor, by Prof. O. W. Walter;

Local Engineering, by Bruce Spence;

Electric Meters, by Floyd Williams, and

High-Line Maintenance, by Ralph Tyler. November 19. Attendance 32.

Pennsylvania State College

Business Meeting. October 28. Attendance 40.

A film, entitled "The Queen of the Waves," was shown. Professor L. A. Doggett gave a talk in which he described the electrical installations of the U. S. S. New Mexico, the U. S. S

Saratoga and other battleships. He also gave an explanation of the action of the gyro-compass and its installations. November 18. Attendance 100.

Canal Zone, by G. J. Cartwright;

Bell Telephone Laboratories, by D. A. McMaster;

New York Edison Company, by J. E. Hogan, and

Westinghouse Elec. & Mfg. Company, by Professor H. I. Tarpley. These talks dealt with recent Summer experiences of some of the members. December 9. Attendance 52.

University of Pittsburgh

Pittsburgh Railways Problems, by G. A. Culbertson, student;

Purification of Circuit-Breaker Oils, by R. L. Johnson; student and

Recent Developments in Palestine, by A. Abulafia, student. November 6. Attendance 29.

Machine-Switching Telephones, by S. H. King, student. November 13. Attendance 26.

The Klydonograph, by E. H. Powell; student;

The Manufacture of Steel Pipe, by D. P. Mitchell, student, and

Harnessing the Tides of the Bay of Fundy, by N. Watkins, student. November 20. Attendance 25.

Purdue University

The Use of Electrical Analogies in Solving Mechanical Problems, by J. A. Long, American Tel. & Tel. Co., and

Telephone Apparatus in the Purdue Telephone Laboratory, by E. B. King, Indiana Bell Telephone Co. October 26. Attendance 40.

Improving Consumer Substations, by A. W. Miller, student, and

Transformer Design and Operation, by A. M. Wiggins, student. November 10. Attendance 80.

The Electric Railway and Its Relation to Industry, by Professor D. D. Ewing, and

Swordfishing, by Professor J. L. Bray. December 1. Attendance 100.

Rensselaer Polytechnic Institute

Work with the New York Edison Company, by Fred Van Olinda;

Work with the United Electric Light and Power Company, by Louis M. Dowell;

Work with Kingston Public Utilities Company, by Luke Holton;

Work with the New Haven Power and Light Company, by Paul Escholtz;

Work with the General Electric Company, at Springfield, by Leslie Hochgraf;

New Methods of Making Transmission-Line Surveys, by Dr. Wm. L. Robb;

New Alloy for Spark-Plug Points, by Dr. M. A. Hunter;

Physics and the Theory of Relativity, by Dr. R. A. Patterson and

Making an Interference Survey by Radio, by Dr. W. J. Williams. November 10. Attendance 106.

Rhode Island State College

The Life and Work of Oliver Heaviside, and

The Einstein Theory of Relativity, by Professor Anderson. November 20. Attendance 27.

The Melrose Substation, by J. Lamb. December 4. Attendance 18.

Rose Polytechnic Institute

Principles of Street Lighting, by G. F. Mudgett, Westinghouse Elec. & Mfg. Co. November 11. Attendance 41.

High-Frequency Waves, by D. R. Werner. December 2. Attendance 43.

South Dakota State School of Mines

Telephone Engineering, by Fred Spain. November 16. Attendance 16.

Swarthmore College

Engineering as a Profession, by A. Prescott Willis. December 10. Attendance 50.

Syracuse University

Business Meeting. The following officers were elected: President, K. N. Cook; Secretary, R. H. Watkins; Treasurer, G. R. Brownell. September 23. Attendance 20.

Commercial Research Engineering, by W. E. Mueller. September 30. Attendance 19.

High-Tension Cables, by E. L. Dunlap. October 7. Attendance 18.

Automobile Braking Systems, by G. R. Brownell. October 14. Attendance 17.

The Dufour High-Frequency Oscillograph, by L. F. Busse. October 21. Attendance 19.

Piezo Crystals and Piezo Electricity, by B. C. Carpenter. October 28. Attendance 19.

The Klydonograph and Its Application to Surge Investigation, by K. N. Cook. November 4. Attendance 20.

Carrier Telephony on High-Voltage Lines, by C. N. Coombe. November 11. Attendance 20.

Street-Railway Power and Line Distribution, by E. R. Fitzgerald. November 18. Attendance 20.

Texas Agricultural and Mechanical College

High-Voltage Transmission Lines, by D. M. Davis, student, and

Power-Plant Design, by R. M. Kennedy, student. November 20. Attendance 83.

Virginia Military Institute

A New Departure in Engineering Education, by Cadet S. A. Carson;

Losses in Iron under the Action of Superposed A-C. and D-C. Excitations, by Cadet L. Metcalfe, and

Electricity as Applied to Medicine, by Cadet R. L. Yeager. December 7. Attendance 21.

Virginia Polytechnic Institute

The New Orthophonic Victrola, by A. R. Green;

New Courses Offered by the University of Pennsylvania, by Mr. Keller, and

The Corn Products Refining Plant, by H. E. Broyles. November 18. Attendance 25.

The Wireless, by Professor Haynes. December 2. Attendance 35.

University of Virginia

A film, entitled "Speeding Up Our Deep-Sea Cables," was shown. November 16. Attendance 23.

University of Washington

The Development of the Submarine Cable, by M. T. Crawford, Puget Sound Power and Light Co. Illustrated with slides. November 4. Attendance 27.

West Virginia University

What Mental Tests Will Do in Industries, by W. L. Nuhfer;

Dipping and Baking Railway-Motor Armatures, by W. F. Davis;

Babbitt Metal, by G. R. Latham;

Advantages of Highway Lighting, by W. A. Williams;

Steam Geysers and Electrical Development, by E. A. Berry;

A Thermostat, by S. McGowan, and

Highway Lighting, by C. W. Moore. November 23. Attendance 28.

Business Meeting. November 30. Attendance 28.

University of Wisconsin

The Value of Non-Professional Subjects to the Engineer, by Professor Edward Bennett;

Accuracy in Engineering Work, by Professor C. M. Jansky, and

The Value of Membership in the Student Branch and National A. I. E. E., by Professor J. T. Rood. November 10. Attendance 140.

Worcester Polytechnic Institute

Business Meeting. The following officers were elected: Chairman, O. H. Brewster; Vice-Chairman, D. A. Calder; Secretary, R. A. Beth; Treasurer, J. F. Wood; Counselor, H. A. Maxfield. November 19. Attendance 21.

My Travels in Mohammedan Countries, by Professor H. B. Smith. December 8. Attendance 60.

University of Wyoming

Business Meeting. The following officers were elected: Chairman, Everett Murray; Vice-Chairman, James Yates; Secretary-Treasurer, Virgil Shinbur; Faculty Advisor, G. H. Sechrist. November 19. Attendance 9.

Engineering Societies Employment Service

Under joint management of the national societies of Civil, Mining, Mechanical and Electrical Engineers cooperating with the Western Society of Engineers. The service is available only to their membership, and is maintained as a cooperative bureau by contributions from the societies and their individual members who are directly benefited.

Offices:—33 West 39th St., New York, N. Y.,—W. V. Brown, Manager.
63 West Jackson Blv'de., Room 1736, Chicago, Ill., A. K. Krauser, Manager.

MEN AVAILABLE.—Brief announcements will be published without charge but will not be repeated except upon requests received after an interval of one month. Names and records will remain in the active files of the bureau for a period of three months and are renewable upon request. Notices for this Department should be addressed to ***EMPLOYMENT SERVICE, 33 West 39th Street, New York City,*** *and should be received prior to the 15th of the month.*

OPPORTUNITIES.—A Bulletin of engineering positions available is published weekly and is available to members of the Societies concerned at a subscription rate of $3 per quarter, or $10 per annum, payable in advance. Positions not filled promptly as a result of publication in the Bulletin may be announced herein, as formerly.

VOLUNTARY CONTRIBUTIONS.—Members obtaining positions through the medium of this service are invited to cooperate with the Societies in the financing of the work by nominal contributions made within thirty days after placement, on the basis of $10 for all positions paying a salary of $2000 or less per annum; $10 plus one per cent of all amounts in excess of $2000 per annum; temporary positions (of one month or less) three per cent of total salary received. The income contributed by the members, together with the finances appropriated by the four societies named above, will it is hoped, be sufficient not only to maintain, but to increase and extend the service.

REPLIES TO ANNOUNCEMENTS.—Replies to announcements published herein or in the Bulletin, should be addressed to the key number indicated in each case, with a two cent stamp attached for reforwarding, and forwarded to the Employment Service as above. Replies received by the bureau after the positions to which they refer have been filled will not be forwarded.

POSITIONS OPEN

ELECTRICAL DESIGNER, who has had experience on oil switches. Salary $200-$250 a month. Location, Chicago. R-7818-R-7-C.

DESIGNER, for manufacturing purposes of such equipment as air break switches, gang operated disconnect switches, bus supports, etc. Experience in simple station operation, design of substations, etc., does not qualify a man for this position. Experience in the actual design and manufacture of the class of equipment described essential. Location, Pennsylvania. R-8118-C.

SALES ENGINEER, technical graduate, for manufacturer of storage batteries. Opportunity. Apply by letter stating age, education and experience. Location, Georgia. R-8208-C.

ELECTRICAL ENGINEER, experienced in developing small electrical machines and devices. Knowledge of spot welding and heat resistance units desirable. Apply by letter stating experience, age, education and salary desired. Location, Middlewest. R-8243-C.

SALES ENGINEER, for manufacturer of electrical heating and control appliances. Apply by letter. Location, San Francisco. R-8257-C-S.

DESIGNING ENGINEER, 30-35, with electrical crane and hoist experience. Apply by letter. Salary $3000 a year. Location, Pennsylvania. R-8205-C.

MEN AVAILABLE

EXECUTIVE, 43, married, thoroughly competent to take charge of offices, plant or factory. Many years' actual experience in organization, personnel management, valuation and appraisal, installations and supervision, office management, correspondent and special confidential investigations. Available at once. Location, New York or New Jersey. C-521.

ENGINEERING EXECUTIVE, position desired with growing company in commercial or engineering capacity, preferably as department head, or assistant to general executive. At present assistant to chief engineer company manufacturing heavy machinery. Ten years' experience since graduation from Rensselaer Polytechnic Institute in design, manufacture heavy machinery, design, manufacture electrical equipment, appraisal of physical property of public service corporations, maintenance of shop equipment, and power plant operation. Authority on application of industrial electrical equipment. Available because of closing of plant with which connected for past seven years. A-280.

PLANT ENGINEER, age 33, technical education, broad experience in the design, construction and maintenance of industrial plants. Specialty oil refineries. New York license. Available immediately. B-9376.

ENGINEER-SCIENTIST, 30, married, educated at M. I. T., three years in chemistry, three years in mathematical physics, graduating in mechanical engineering. Employed as technical report writer for research laboratory of G. E. and as industrial physicist and designer by Corning Glass Works. Executive experience and broad training in commercial subjects. Employed. B-9930.

ENGINEERING EXECUTIVE, nine years' experience, mainly with one large power company in station operation, distribution lines, substation construction, transmission line construction, distribution engineering, commercial work including power sales. Now district superintendent charge distribution entire district, also entire charge local offices reporting to district office. Graduate electrical engineer, G. E. test course training. Wants place as assistant to chief engineer, or general manager electric power company, or in consulting engineering firm. Married, 32. C-650.

ENGINEERING EXECUTIVE, 44, married, considerable experience selection, installation, operation wide variety electrical and mechanical equipment. G. E. test, sales engineering, steel mill superintendent. Successful record building efficient operating organization. Effective in practical analysis and presentation of industrial problems. Refer present employer. Available January first. Location anywhere. C-615.

ELECTRICAL ENGINEER, 30, technical graduate, desires position as assistant engineer or executive. Eighteen months G. E. test, four years assistant foreman on installation, testing and development work. Will not consider a place that has no chance for advancement. Location, greater New York City. Available on two weeks' notice to present employer. C-702.

ELECTRICAL ENGINEER, college graduate with five years' experience in power house and substation design, as well as construction, desires responsible position with public utility or engineering firm, offering opportunity. Available on reasonable notice. C-692.

ELECTRICAL ENGINEER, research, designing and executive practice, particularly in gasoline-electric traction problems, fully acquainted with theory and practice of electrical, electro-physical and mechanical problems and shop practice, desires responsible permanent position. At present chief and consulting engineer. Available in short time. Pittsburgh or East preferred. C-693.

GRADUATE OF THE UNIVERISTY OF PENNSYLVANIA in industrial management, four years' experience in electrical construction, drafting and machine design in executive capacity. Age 26. Available January 15, 1926. C-694.

ELECTRO-PHYSICIST AND RADIO ENGINEER, age 40, married, former professor in Russian technical colleges; publications and inventions in x-rays, positive rays, radio, measuring instruments, agricultural applications. Two years' industrial experience in radio receivers and parts in United States. Employed in testing laboratory of radio concern. Desires research, radio engineering, or testing position. Available on one week's notice. B-371.

ELECTRICAL AND VALUATION ENGINEER, 32, single, good working knowledge Spanish. Ten years' practical experience installation, operation of steam, hydro-electric plants, electric mining, industrial and public utility equipment, including two years General Electric Company's tests, two years with Public Service Commission of New York State. Now specializing in inventories, appraisals, property reports, investigations, classified accounting systems for public utilities, mining and industrial corporations. Salary $300 per month. B-9636.

ELECTRICAL AND MECHANICAL ENGINEER, 45, married, with very wide experience in dredging, construction and executive work, desires a permanent position with public utility, or consulting, or construction firm. Willing to go anywhere. Perfect knowledge of modern languages. Available end of January or earlier. C-720.

ELECTRICAL ENGINEER, 25, single, Columbia graduate 1925, extensive training of six years with ability to use his hands and his head; ten years' electrical and mechanical shop experience, seven months' experience in test department of large power company, desires a position with a manufacturing company where there is an opportunity for advancement. Wishes to specialize in electric relays and control devices and would be most interested in this work. Available on two weeks' notice. Location, anywhere. C-237.

TECHNICAL GRADUATE, desires position with established radio manufacturing concern, domestic or foreign. Present position with U. S. Government on care, upkeep, and maintenance of radio direction finding stations. C-723.

PROFESSOR, electrical engineering, would consider making a change. Ten years' of teaching experience. Well acquainted with industrial requirements through design, application and construction experience. Desires professorship in an institution where research is encouraged. B-7083.

STUDENT ENGINEER, age 22, single, seventeen months on G. E. test, desires position in power plant, preferably in connection with generation and transmission. Available on two weeks' notice. Location, New England, or Eastern New York. C-731.

MEMBERSHIP — Applications, Elections, Transfers, Etc.

ASSOCIATES ELECTED DECEMBER 11, 1925

AGENS, HERBERT M., Asst. to Electrical Engineer, The Foundation Co., 120 Liberty St., New York, N. Y.

ARMERO, JOSE P., Electrical Engineer, Operating Dept., Alabama Power Co., Birmingham, Ala.

BARBER, HARRY ORVAL, Supt., Snoqualmie Falls Generating Sta., Puget Sound Power & Light Co., Snoqualmie, Wash.

BATES, L. W., Engineer in charge of Automatic Substations, Appalachian Power Co., Bluefield, W. Va.

BOOTHE, EUGENE F., Electrician, Marshall Electric Co., 3225A Locust St., St. Louis, Mo.

BUSCH, HUGO WILLIAM, Designing & Maintaining of Test Equipment, Ware Radio Corp., 543 West 42nd St., New York, N. Y.

CARVER, DELMONT WILSON, Charge of Meter Dept., Brevard County Power Co., Melbourne, Fla.

CASSELL, WALLACE LEWIS, Instructor, Elec. Engg. Dept., University of Colorado, Boulder, Colo.

CAYLOR, RALPH A., Service Manager, The E. H. Walker Co., 210-212 N. Erie St., Toledo, Ohio.

CHRISTIE, SOREN L., Jr., Electrical Engineer, Elec. Heating Engg. Dept., Westinghouse Elec. & Mfg. Co., East Pittsburgh; res., Wilkinsburg, Pa.

CLANCEY, JOSEPH A., Jr., Production Manager, Gray Electro Chemical Laboratory, Inc., 9-11 W. 20th St., Bayonne, N. J.

*CONNOLLY, ROBERT COTTMAN, Asst. Electrical Engineer, Western Sugar Refinery, San Francisco, Calif.

CONOLEY, ALEXANDER GORMAN, Division Line Inspector, American Tel. & Tel. Co., 928 Hurt Bldg., Atlanta, Ga.

*CORCORAN, HARRY ROBERT, Sales Engineer, Electric Controller & Mfg. Co., 2700 E. 79th St., Cleveland, Ohio.

*CRANKALL, RICHARD JOHN, Technical Writer, Engg. Dept., National Lamp Works, General Electric Co., Nela Park, Cleveland, Ohio.

CULLINAN, CORNELIUS, Construction Superintendent, Public Service Production Corp., 15 E. Park St., Newark, N. J.

DANCE, HERBERT ERNEST, Asst. Consulting Engineer, Lecturer, Elec. Engg. Dept., Birkenhead Technical School, Birkenhead, Eng.

DAVIS, ROWLAND FENNER, Engineer, O. & E. Dept., American Tel. & Tel. Co., 195 Broadway, New York; res., Brooklyn, N. Y.

DEAN, SAMUEL MILLS, Engineer, The Detroit Edison Co., 2000 Second Ave., Detroit, Mich.

DEARLOVE, TOM CARLTON, Electrical Engineering, 19 Homewood Ave., Toronto, Ontario, Can.

*De VEYHER, CONSTANTIN, Fieldman, Transmission Engg. Dept., So. California Telephone Co., 433 S. Olive St., Los Angeles, Calif.

DIGGINS, GEORGE J., Jr., Asst. Engineer, Railway Electrification, Gibbs & Hill, Pennsylvania Sta., New York, N. Y.

DRUSHEL, RAYMOND WENDELL, Division Operator, The Ohio Public Service Co., Alliance, Ohio.

ECKERSLEY, JAMES, Foreman, Meter Dept., Toronto Hydro-Electric System, 225 Yonge St., Toronto, Ont., Can.

ELBERTY, ROBERT S., Jr., Engineer, American Laundry Machinery Co., Norwood; res., Cincinnati, Ohio.

*FANAFF, PAUL ANDREW, Electrical Work, 628 Ogden Ave., Toledo, Ohio.

FLEMING, WILLIAM RAYMOND, Electrical Switchboard Operator, Commonwealth Edison Co., Fisk Street Station, Chicago, Ill.

GARDNER, JOHN H., Jr., Captain, U. S. A., Fort Hayes, Columbus, Ohio.

GETTESS, GEORGE HAROLD, Engineer, The Detroit Edison Co., 2000 Second Ave., Detroit, Mich.

GLAZIER, FORREST SMOOT, Sales Engineer, W. A. Ramsay, Ltd., 74 S. Queen St., Honolulu, T. H.

GRISWOLD, RALPH G., Instructor, Elec. Engg. Dept., Purdue University, West Lafayette, Ind.

HARDY, ROBERT S., Asst. General Manager, Niagara Lockport & Ontario Power Co., 608 Lafayette Bldg., Buffalo, N. Y.

*HOFFMAN, HENRY JULIUS, Student Engineer, General Electric Co., Erie, Pa.

HORN, HENRY GEORGE, Designing Engineer, General Electric Co., Pittsfield, Mass.

*HOWERTH, DWIGHT GOLDWIN, Asst. to Statistician, Adirondack Power & Light Corp., Clinton St., Schenectady, N. Y.

HUBBARD, McCOY, Asst. Engineer, Southern Utilities Co., West Palm Beach, Fla.

HUBINGER, JOSEPH EDWARD, Jr., Construction Dept., Mississippi River Power Co., Keokuk, Iowa; for mail Warsaw, Ill.

ISAAC, ARCHIBALD CHARLES THOMPSON, Mechanical Engineer, General Electric Co., Pittsfield, Mass.

JOHNSTON, ROBERT FOSTER, Estimator, General Electric Co., 120 Broadway, New York, N. Y.

KOLDOFF, ANTHONY GEORGE, Cabling Engineer, Western Electric Co., Inc., 24th St., & Cicero Ave., Cicero; res., Elmhurst, Ill.

KOPATZKE, GEORGE A., Service Manager, Wagner Electric Corp., 501 Broadway, Milwaukee, Wis.

*KWONG, FREDERICK KIMMING, Chief Engineer, Toi-shan Electric Light & Power Co., Ltd., 97 Wing Lok St., Hongkong, China.

LARSON, NILS GERON, Electrical Drafting, The International Paper Co., 100 E. 42nd St., New York, N. Y.

LEROY, EVERETT ROOSEVELT, Engineering Assistant, New York Telephone Co., 104 Broad St., New York, N. Y.

LOCHNER, BJORN R., Draftsman, Westinghouse Elec. & Mfg. Co., Sharon, Pa.

LOSINSKY, JACOB, Control Engineer, Volhov Hydro-Electric Power Plant Works, A. S. E. A., Ludvika, Sweden.

MARSH, HALLOCK SNYDER, Service Clerk, Radio Corp. of America, 925 Fort St., Honolulu, T. H.

MILTON, ROBERT McCARLEY, Electrical Inspector, U. S. Engineer's Office, Wilson Dam, Florence, Ala.

*McNAIR, J. W., Engr. Assistant, United Electric Light & Power Co., 56 Cooper Square, New York, N. Y.

McNALLY, CLAUDE, Electrical Instructor & Engineer, Academy High School, Erie, Pa.

MILLER, WILLIAM G., Electrical Engineer, Designing Dept., Electric Bond & Share Co., 71 Broadway, New York, N. Y.

NUTTALL, BRANSON, Switchboard Engineer, Messrs. Ferguson Pailin Ltd., Higher Openshaw, Manchester, Eng.

PARRY, EDWARD M., 202 Howard St., Passaic Park, N. J.

PALMER, HARLAN B., Instructor, Elec. Engg. Dept., University of Colorado, 810 14th St., Boulder, Colo.

PETTERSEN, HERBERT CHRISTIAN, Draftsman, Inside Plant Dept., Commonwealth Edison Co., 72 W. Adams St., Chicago, Ill.

PULLEN, JOHN THOMAS, Jr., Asst. Engineer, Southern Utilities Co., West Palm Beach, Fla.

PYLE, MARK, Engineer, Puget Sound Power & Light Co., Eastern Dist., Wenatchee, Wash.

QUINN, JOSEPH JOHN, Estimating Engineer, Engg. Dept., Duquesne Light Co., 435 6th Ave., Pittsburgh, Pa.

*RICHARDS, KENNETH WEATHERBY, Cadet Engineer, Public Service Electric & Gas Co., Newark, N. J.

ROBINSON, TREVOR ARMSTRONG, Draughtsman, Northern States Power Co., 76 W. 3rd St., St. Paul, Minn.

ROITBURD, BERNARD, 2905 Grand Concourse, Bronx, New York, N. Y.

ROTE, OAKLEIGH C., Student Engineer, General Electric Co., Schenectady, N. Y.

RUDERSHAUSEN, FRANZ JOSEF, Laboratory Assistant, Chile Exploration Co., Chuquicamata, Chile, So. Amer.

RUMP, SIGURD, Yarmouthville, Maine.

SALERNO, MARCUS JOSEPH, 515 W. 111th St., New York, N. Y.

SANDSTROM, PER N., Draftsman, Commonwealth Edison Co., 72 W. Adams St., Chicago, Ill.

SAYRE, EARL ROLAND, Sales Engineer, Hart & Hegeman Co., 623 W. Jackson Blvd., Chicago, Ill.

SCHENCK, IRVING PRIESTLEY, Electrical Engineer, Day & Zimmerman, 1600 Walnut St., Philadelphia, Pa.; for mail, Plainfield, N. J.

SCLAVOUNOS, LAMPROS P., Manager, Member, Board of Directors, The Egyptian Radio Co., Cheriff Pacha Street 16, Alexandria, Egypt.

SCOTT, ARTHUR H., Engineer, General Electric Co., Pittsfield, Mass.

SIMPSON, WALTER LA VERN, Electrical Engineer, Canadian & General Finance Co., 357 Bay St., Toronto, Ont., Can.

SIVIAN, LEON J., Research Engineer, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.

SOCOLOFSKY, PAUL, Student, Industrial Elec. Engg. Dept., Pratt Institute, 254 Clermont Ave., Brooklyn, N. Y.

STAROSSELSKY, DMITRY V., Inspector, Electrical Construction Bureau, Brooklyn Edison Co., Pearl & Willoughby Sts., Brooklyn, N. Y.

STEWART, PHILIP BRUCE, Supt. of Transmission, Union Gas & Electric Co., 4th & Plum Sts., Cincinnati, Ohio.

SUMMERS, CHARNELLE H., Jr., Asst. Distribution Engineer, Southern Utilities Co., West Palm Beach, Fla.

TAYLOR, PAUL B., Instructor, Engineering School, Drexel Institute, Philadelphia, Pa.

THOMAS, WINTHROP ATHERTON, Asst. Engineer, Elec. Engg. Dept., New York Edison Co., 124 E. 15th St., New York, N. Y.

*THOMASON, FREDERICK LAYTON, Engineer, Murrie & Co., 45 E. 17th St., New York; res., Brooklyn, N. Y.

THOMPSON, SUMNER MATELL, Electrical Inspector, Bureau of Power & Light, City of Los Angeles, 120 E. 4th St., Los Angeles, Calif.

WILKINSON, GEORGE DAVID, Division Traffic Inspector, Western Union Telegraph Co., 24 Walker St., New York, N. Y.

*WOOD, A. ROYAL, Ass't Supervisor, The Philadelphia Electric Co., 2301 Market St., Philadelphia, Pa.

Total 82

*Formerly Enrolled Students

ASSOCIATES REELECTED DECEMBER 11, 1925

ASHLEY, ALLEN, Special Representative, Condit Electrical Mfg. Corp., 152 W. 42nd St., New York, N. Y.

TUCKER, ALLAN WINTHROP, Member, Technical Staff, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.; res., West New York, N. J.

MEMBERS ELECTED DECEMBER 11, 1925

BOLIS, PIETRO, Chief Engineer, Transformer Factory, Compagnia Generale di Elettricita, Via Borgognone, 40, Milan, Italy.

DOW, JAY L., Telephone Engineer, Bell Tel. Laboratories, Inc., 463 West St., New York, N. Y.

DREESE, ERWIN ERNEST, Chief Engineer, Lincoln Electric Co., Cleveland, Ohio.

PERSHAD, BALA, Supt., Telephone Dept., H. E. H., The Nizam's Government, Hyderabad, Deccan, India.

RUTH, CONANT W., President, C. W. Ruth Engineering Co., 8 S. Dearborn St., Chicago, Ill.

SCUDDER, FREDERICK J., Technical Staff, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.

van MEETEREN, WILLIAM, General Manager, Siemens-Mexico, S. A., Puente de Alvarado, 91-99, Mexico, D. F., Mex.

TRANSFERRED TO GRADE OF FELLOW DECEMBER 11, 1925

PANNELL, ERNEST V., Technical Advisor to the British Aluminum Co., New York, N. Y.

TRANSFERRED TO GRADE OF MEMBER DECEMBER 11, 1925

BAILEY, EDGAR L., Electrical Engi eer, Detroit, Mich.

BARTON, ROBERT C., Engineer on Construction Methods, Pacific Tel. & Tel. Co., San Francisco, Calif.

BROWN, HARRY F., Assistant Electrical Engineer, N. Y., N. H. & H. R. R. Co., New Haven, Conn.

CAMP, C. R., Head Draftsman, Commonwealth Edison Co., Chicago, Ill.

CANNADY, N. E., State Electrical Engineer, Raleigh, N. C.

CODDING, HENRY W., Assistant Engineer, Elec. Engg. Dept., Public Service Production Co., Newark, N. J.

COLEY, WALTER R., Plant Superintendent, Leeds & Northrup Co., Philadelphia, Pa.

CROTHERS, HAROLD M., Professor of Electrical Engineering, South Dakota State College, Brookings, S. D.

D'ALTON, F. K., Assistant Laboratory Engineer, Hydro-Electric Power Commission of Ontario, Toronto, Ont.

DANA, ALAN S., Research Engineer, Kerite Insulated Wire & Cable Co., Seymour, Conn.

DAVIS, LEE I., Test Engineer, Otis Elevator Co., Yonkers, N. Y.

DuBOIS, DELAFIELD, Electrical Research Engineer, Safety Insulated Wire & Cable Co., Bayonne, N. J.

FINCH, FLOYD R., Electrical Engineer, General Electric Co., Pittsfield, Mass.

GAGE, DAVID H., Foreign Wire Relations Engineer, Postal Telegraph-Cable Co., 253 Broadway, New York, N. Y.

GEORGE, F. R., Engineer of Operation, Pacific Gas & Electric Co., San Francisco, Calif.

HALL, HERBERT S., Electrical Engineer on Valuation, Murrie & Co., New York, N. Y.

HYER, RAYMOND G., Superintendent Design & Construction, Westchester Lighting Co., Yonkers, N. Y.

JOLLYMAN, JOSIAH P., Chief, Div. of Hydroelectric & Transmission Engineering, Pacific Gas & Electric Co., San Francisco, Calif.

KRUG, FREDERICK, Superintendent of Power Production, Porto Rico Railway, Light & Power Co., San Juan, P. R.

MACK, CARL T., Attorney at Law, Patent Causes, Washington, D. C.

MAC LAREN, MALCOLM, Professor of Electrical Engineering, Princeton University, Princeton, N. J.

McCABE, GORDON B., Technical Engineer Operating Dept., Detroit Edison Co., Detroit, Mich.

METZENHEIM, HENRY H., Instructor in Electricity & Mathematics, Newark Technical School, Newark, N. J.

MICHETTI, O. D., Lieut. Commander, Engineering, Argentine Navy, Quincy, Mass.

PAXTON, E. B., Engineer, General Engineering Dept., General Electric Co., Schenectady, N. Y.

REID, MEREDITH W., Electrical Engineer, General Engineering & Management Corp. New York, N. Y.

RUSSELL, ROY E., Estimator, Frank J. York, Co., Detroit, Mich.

SMITH, LOUIS G., Assistant to General Superintendent, Consolidated Gas, Electric Light & Power Co., Baltimore, Md.

SNYDER, EDWARD B., Manager, Sales & Engineering, Hi-Tension Ins. Div., Ohio Brass Co., Mansfield, Ohio.

SPOONER, HENRY W., Engineer, The Foundation Co., New York, N. Y.

STEMLER, EDWARD J., Chief Operator, Interborough Rapid Transit Co., New York, N. Y.

TALBOT, EMMETT D., Engineer, Bell Telephone Laboratories, New York, N. Y.

TOUR, GREGORY I., Assistant Engineer, Stone & Webster, Inc., Boston, Mass.

TRUEBLOOD, HOWARD M., Engineer, Dept of Development & Research, American Telephone & Telegraph Co., New York, N. Y.

van NIEUKERKEN, J. M., Assistant Engineer, Cleveland Union Terminals Co., Cleveland, Ohio.

VINET, EUGENE, Assistant to Vice-President in charge of Engineering, Middle West Utilities Co., Chicago, Ill.

WOOD, E. M., Assistant Engineer, Hydro-Electric Power Commission, Toronto, Ont.

RECOMMENDED FOR TRANSFER

The Board of Examiners, at its meeting held December 7, 1925, recommended the following members for transfer to the grade of membership indicated. Any objection to these transfers should be filed at once with the National Secretary.

To Grade of Fellow

BETTIS, ALEXANDER E., Vice-President, Kansas City Power & Light Co., Kansas City, Mo.

CURTIS, HARVEY L., Senior Physicist, Bureau of Standards, Department of Commerce, Washington, D. C.

DANN, WALTER M., Electrical Engineer, Westinghouse Electric & Mfg. Co., Sharon, Pa.

HOBART, K. E., Superintendent Overhead Lines, Commonwealth Edison Co., Chicago, Ill.

PRINCE, DAVID C., Research Engineer, General Electric Co., Schenectady, N. Y.

TO Grade of Member

CAMPBELL, THADDEUS C., Telephone Engineer, Systems Development Dept., Bell Telephone Laboratories, New York.

EWENS, W. SYDNEY, District Manager, Alfred Collyer & Co., Toronto, Ont.

HAZELTINE, HAROLD L., Engineer of Insulation, Sterling Varnish Co., Pittsburgh, Pa.

JOHNSON, EDWARD J., Member of Technical Staff, Bell Telephone Laboratories, New York

MEYER, A. A., Assistant General Superintendent Detroit Edison Co., Detroit, Mich.

NOSS, MARSENA A., Chief Engineer, International Telepost Co., New York.

ROBINSON, BLIGHT S., Engineer, R. W. Cramer & Co., Inc., New York.

SHEPARD, ROBERT B., Electrical Engineer, Underwriters' Laboratories, New York

SILSBEE, FRANCIS B., Physicist, Bureau of Standards, Department of Commerce, Washington, D. C.

SMITH, EVERETT H., Supervising Equipment Design Engineer, Bell Telephone Laboratories, New York.

SNIDER, GEORGE E., Chief Electrical Engineer, Ohio Public Service Co., Cleveland, O.

STEVENS, ALEXANDER C., Electrical Engineer, General Electric Co., Schenectady, N. Y.

WEIGHT, JOHN W., Head, Industrial Truck and Locomotive Dept., Electric Storage Battery Co., New York.

WILKINS, ROY, Assistant Engineer, Dept. of Hydro-Elec. & Transmission Engg., Pacific Gas & Electric Co., San Francisco, Calif.

APPLICATIONS FOR ELECTION

Applications have been received by the Secretary from the following candidates for election to membership in the Institute. Unless otherwise indicated, the applicant has applied for admission as an Associate. If the applicant has applied for direct admission to a higher grade than Associate, the grade follows immediately after the name. Any member objecting to the election of any of these candidates should so inform the Secretary before January 31, 1926.

Abe, T., Japanese Government Railways, New York, N. Y.

Adam, A. O., Jr., Bell Telephone Laboratories, Inc., New York, N. Y.

Adkins, A. H., Electric Storage Battery Co., Washington, D. C.

Ahrens, J. H., Henry & Wright Mfg. Co., Hartford, Conn.

Ahrling, G. A., Murrie & Co., Inc., New York, N. Y.

Aikins, N. B., New England Tel. & Tel. Co., Portland, Me.

STUDENTS ENROLLED DECEMBER 10, 1925

Achenbach, Jay Oswald, Cornell Univ.
Adams, Hampton C., Univ. of Ky.
Allen, Lesler E., University of Kansas
Allen, William B. C., Yale Univ.
Alvarado, Everardo M., Milwaukee School ofE ngg.
Anders, Russell D., Penn. State College
Andriacchi, Louis A. Marquette Univ.
Arehart, Narbin E., U. of Notre Dame
Askey, Russel O., Univ. of Ill.
Babcock, John W., University of Nevada
Barshewski, Francis A. Mil. School of Engg.
Batchelor, Harold, Kans. St. Agri. College
Bauer, Lawrence J., State College of Washington
Baur, Roy E., Armour Inst.
Beckman, Clifford A., Armour Inst.
Bell, Delamar T., Ga. School of Tech.
Bellaschi, Peter L., Mass. Inst. of Technology
Benner, Philip E., Iowa State College
Benson, Arnold, University of Nevada
Bergstrom, Francis A., Ore. Inst. of Tech.
Bernhard, Carl W. H., University of Wash.
Beth, Richard A., Worcester Poly. Inst.
Bishop, Charles B., Univ. of British Columbia
Bliss, Donald S., Worcester Poly. Inst.
Bostwick, Myron A., State College of Washington
Bower, Marcy J., Univ. of Delaware
Bowyer, Dee, Kansas State Agri. College
Boyd, Spencer W., Georgia School of Tech.
Boyle, Stanley C., Univ. of Notre Dame
Brandt, R. T., Case School Appl. Science
Braunsdorf, Joseph A., Univ. of Notre Dame
Breen, Raymond K., Notre Dame Univ.
Bretschneider, Max E., Northeastern Univ.
Brewster, Oliver H., Worcester Poly. Institute
Brooks, Gerald, E., Okla. Agri. & Mech. College
Brown, Arthur R., Worcester Poly. Inst.
Brown, Paul M., University of Colorado
Brumbaugh, Claude J., Case School Applied Science
Buchanan, Thomas G., University of British Columbia
Bundy, O. Le Grand, Cornell University
Bunte, Herman C., Kansas State College
Burchfield, Clinton, R., Penn., State College
Burcky, Charles W., Armour Inst.
Burns, Leroy H., Yale Univ.
Burton, Raymond E., Kansas State Agri. College
Calder, Donald A., Worcester Poly. Inst.
Camelio, John F., Northeastern Univ.
Capodanno, Rocco J., Univ. of Illinois

Officers A. I. E. E. 1925-1926

PRESIDENT
(Term expires July 31, 1926)
M. I. PUPIN

JUNIOR PAST PRESIDENTS

(Term expires July 31, 1926) HARRIS J. RYAN
(Term expires July 31, 1927) FARLEY OSGOOD

VICE-PRESIDENTS

(Terms expire July 31, 1926)
HAROLD B. SMITH (District No. 1)
EDWARD BENNETT (District No. 5)
JOHN HARISBERGER (District No. 9)
L. F. MOREHOUSE (District No. 3)
H. W. EALES (District No. 7)

(Terms expire July 31, 1927)
P. M. DOWNING (District No. 8)
HERBERT S. SANDS (District No. 6)
W. E. MITCHELL (District No. 4)
ARTHUR G. PIERCE (District No. 2)
W. P. DOBSON (District No. 10)

MANAGERS

(Terms expire July 31, 1926)
H. M. HOBART
ERNEST LUNN
G. L. KNIGHT

(Terms expire July 31, 1928)
JOHN B. WHITEHEAD
J. M. BRYANT
E. B. MERRIAM

(Terms expire July 31, 1927)
W. M. McCONAHEY
W. K. VANDERPOEL
H. P. CHARLESWORTH

(Terms expire July 31, 1929)
M. M. FOWLER
H. A. KIDDER
E. C. STONE

NATIONAL TREASURER — **NATIONAL SECRETARY**
(Terms expire July 31, 1926)
GEORGE A. HAMILTON — F. L. HUTCHINSON

HONORARY SECRETARY
RALPH W. POPE

GENERAL COUNSEL
PARKER & AARON
30 Broad Street, New York

PAST-PRESIDENTS—1884-1925

*Norvin Green, 1884-5-6.
*Franklin L. Pope, 1886-7.
*T. Commerford Martin, 1887-8.
Edward Weston, 1888-9.
Elihu Thomson, 1889-90.
*William A. Anthony, 1890-91.
*Alexander Graham Bell, 1891-2.
Frank Julian Sprague, 1892-3.
*Edwin J. Houston, 1893-4-5.
*Louis Duncan, 1895-6-7.
*Francis Bacon Crocker, 1897-8.
A. E. Kennelly, 1898-1900.
Carl Hering, 1900-1.
*Charles P. Steinmetz, 1901-2.
Charles F. Scott, 1902-3.
Bion J. Arnold, 1903-4.
John W. Lieb, 1904-5.
*Schuyler Skaats Wheeler, 1905-6.
*Samuel Sheldon, 1906-7.
*Henry G. Stott, 1907-8.
Louis A. Ferguson, 1908-9.
Lewis B. Stillwell, 1909-10.
Dugald C. Jackson, 1910-11.
Gano Dunn, 1911-12.
Ralph D. Mershon, 1912-13.
C. O. Mailloux, 1913-14.
Paul M. Lincoln, 1914-15.
John J. Carty, 1915-16.
H. W. Buck, 1916-17.
E. W. Rice, Jr., 1917-18.
Comfort A. Adams, 1918-19.
Calvert Townley, 1919-20.
A. W. Berresford, 1920-21.
William McClellan, 1921-22.
Frank B. Jewett, 1922-23.
Harris J. Ryan, 1923-24.
Farley Osgood, 1924-25.

*Deceased.

LOCAL HONORARY SECRETARIES

T. J. Fleming, Calle B. Mitre 519, Buenos Aires, Argentina, S. A.
Carroll M. Mauseau, Caixa Postal No. 571, Rio de Janeiro, Brazil, S. A.
Charles le Maistre, 28 Victoria St., London, S. W. 1, England.
A. S. Garfield, 45 Bd. Beausejour, Paris 16 E, France.
H. P. Gibbs, Tata Sons Ltd., 24 Bruce Road, Bombay—1, India.
Guido Semenza, 39 Via Monte Napoleone, Milan, Italy.
Eiji Aoyagi, Kyoto Imperial University, Kyoto, Japan.
P. H. Powell, Canterbury College, Christchurch, New Zealand.
Axel F. Enstrom, 24a Grefturegatan, Stockholm, Sweden.
W. Elsdon-Dew, P. O. Box 4563, Johannesburg, Transvaal, Africa.

A. I. E. E Committees

GENERAL STANDING COMMITTEES

EXECUTIVE COMMITTEE

M. I. Pupin, Chairman, 1 W. 72nd St., New York
Farley Osgood. Vice-Chairman
H. P. Charlesworth, G. A. Hamilton, G. L. Knight,
H. W. Eales W. K. Vanderpoel.

FINANCE COMMITTEE

G. L. Knight, Chairman, Pearl & Willoughby Sts., Brooklyn, N. Y.
L. F. Morehouse W. K. Vanderpoel

MEETINGS AND PAPERS COMMITTEE

E. B. Meyer, Chairman, 80 Park Place, Newark, N. J.
E. H. Hubert, Secretary, 33 W. 39th St., New York
A. W. Berresford, H. W. Eales, C. E. Skinner
E. E. F. Creighton, J. B. Macdonald, Harold B. Smith.
L. W. W. Morrow
Chairman of Committee on Coordination of Institute Activities, ex-officio.
Chairmen of technical committees, *ex-officio.*

PUBLICATION COMMITTEE

L. F. Morehouse, Chairman, 195 Broadway, New York
F. L. Hutchinson, Donald McNicol, J. H. Morecroft.
E. B. Meyer,

COMMITTEE ON COORDINATION OF INSTITUTE ACTIVITIES

Farley Osgood, Chairman, 80 Park Place, Newark, N. J.
F. L. Hutchinson, E. B. Meyer, W. I. Slichter,
G. L. Knight, L. F. Morehouse, Harold B. Smith.

BOARD OF EXAMINERS

Erich Hausmann, Chairman, Polytechnic Institute of Brooklyn, Brooklyn, N. Y.
H. W. Drake, Harold Goodwin, Jr., W. M. McConahey,
E. H. Everit, F. V. Magalhaes, N. L. Pollard,
F. M. Farmer, W. I. Slichter.

SECTIONS COMMITTEE

Harold B. Smith, Chairman, Worcester Polytechnic Institute, Worcester, Mass.
H. H. Henline, W. B. Kouwenhoven, Herbert S. Sands.
C. E. Magnusson,
Chairmen of Sections, *ex-officio.*

COMMITTEE ON STUDENT BRANCHES

C. E. Magnusson, Chairman, University of Washington, Seattle, Wash.
C. Francis Harding, Charles F. Scott, W. H. Timbie.
Harold B. Smith,
Student Branch Counselors, ex-officio.

MEMBERSHIP COMMITTEE

J. L. Woodress, Chairman, 1806 Pine Street, St. Louis, Mo.
R. B. Bonney,
J. M. Bryant, E. E. Dorting George E. Quinan,
C. K. Chapin, R. B. Mateer, A. E. Soderholm,
H. C. Don Carlos, S. H. Mortensen, J. F. Warwick.
L. S. O'Roark.
Chairmen of Section membership committees, *ex-officio.*

HEADQUARTERS COMMITTEE

H. A. Kidder, Chairman, 600 W. 59th Street, New York
F. L. Hutchinson, G. L. Knight.

LAW COMMITTEE

W. I. Slichter, Chairman, Columbia University, New York
H. H. Barnes, Jr., L. F. Morehouse, Charles A. Terry.
R. F. Schuchardt,

PUBLIC POLICY COMMITTEE

Gano Dunn, Chairman, 43 Exchange Place, New York
A. W. Berresford, F. B. Jewett, William McClellan,
H. W. Buck, John W. Lieb, Harris J. Ryan.

STANDARDS COMMITTEE

Executive Committee

H. S. Osborne, Chairman, 195 Broadway, New York
H. E. Farrer, Secretary, 33 W. 39th Street, New York
W. A. Del Mar, A. M. MacCutcheon, L. T. Robinson,
H. B. Gear, J. Franklin Meyer, C. H. Sharp
C. R. Harte, F. D. Newbury, C. E. Skinner,
H. M. Hobart, Harold Pender, R. H. Tapscott,
G. L. Knight, F. L. Rhodes. H. R. Woodrow,

Ex-officio

Chairmen of Working Committees
Chairmen of A. I. E. E. delegations on other standardizing bodies.

EDISON MEDAL COMMITTEE

Appointed by the President for term of five years.

(Terms expire July 31, 1926)
B. A. Behrend, John H. Finney, C. S. Ruffner.
(Terms expire July 31, 1927)
Gano Dunn, Chairman, F. A. Scheffler, W. R. Whitney.
(Terms expire July 31, 1928)
C. C. Chesney, Robert A. Millikan, M. I. Pupin.
(Terms expire July 31, 1929)
N. A. Carle, W. C. L. Eglin, John W. Lieb.
(Terms expire July 31, 1930)
George Gibbs, Samuel Insull, Ralph D. Mershon.

Elected by the Board of Directors from its own membership for term of two years.

(Terms expire July 31, 1926)
L. F. Morehouse, Harris J. Ryan, Harold B. Smith.
(Terms expire July 31, 1927)
W. P. Dobson, Farley Osgood, A. G. Pierce.

Ex-Officio

M. I. Pupin, President, George A. Hamilton, National Treasurer,
F. L. Hutchinson, National Secretary

COMMITTEE ON CODE OF PRINCIPLES OF PROFESSIONAL CONDUCT

John W. Lieb, Chairman, 124 E. 15th Street, New York
C. A. Adams, G. Faccioli, L. F. Morehouse,
A. H. Babcock, R. D. Mershon, C. E. Skinner.

COMMITTEE ON AWARD OF INSTITUTE PRIZES

E. B. Meyer, Chairman, 80 Park Place, Newark, N. J.
L. F. Morehouse, Percy H. Thomas.

COMMITTEE ON AWARD OF COLUMBIA UNIVERSITY SCHOLARSHIPS

W. I. Slichter, Chairman, Columbia University, New York
Francis Blossom, H. C. Carpenter.

COMMITTEE ON SAFETY CODES

Paul Spencer, Chairman, 1401 Arch St., Philadelphia, Pa.
F. A. Barron, Philander Betts, W. J. Canada, R. N. Conwell, J. V. B. Duer, J. C. Forsyth, R. C. Fryer, D. H. Gage, H. B. Gear, P. J. Howe, L. C. Ilsley, M. G. Lloyd, Ernest Lunn, Wills Maclachlan, J. C. Martin, J. E. Moore, R. W. E. Moore, George Quinan, Joseph Sachs, H. R. Sargent, W. H. Sawyer, M. L. Sindeband, H. S. Warren.

SPECIAL COMMITTEES

INSTITUTE PRIZES—POLICIES AND PROCEDURE

L. W. W. Morrow, Chairman, *Electrical World*, 10th Ave. & 36th St., New York
H. P. Charlesworth, H. A. Kidder, C. E. Magnusson, M. E. Skinner, A. C. Stevens.

LICENSING OF ENGINEERS

Francis Blossom, Chairman, Sanderson & Porter, 52 William Street, New York
H. W. Buck, Gano Dunn, L. E. Imlay, E. W. Rice, Jr.

TECHNICAL ACTIVITIES

A. G. Pierce, Chairman, 1239 Guardian Building, Cleveland, Ohio
H. P. Charlesworth, H. M. Hobart, H. A. Kidder, J. B. Whitehead.

TECHNICAL COMMITTEES

COMMUNICATION

H. P. Charlesworth, Chairman, 195 Broadway, New York
F. L. Baer, O. B. Blackwell, L. W. Chubb, Charles E. Davies, H. W. Drake, Major P. W. Evans, R. D. Evans, E. H. Everit, L. F. Fuller, D. H. Gage, S. P. Grace, P. J. Howe, F. H. Kroger, N. M. Lash, Ray H. Manson, R. D. Parker, H. S. Phelps, Lieut. Comm. B. B. Ralston, F. A. Raymond, Chester W. Rice, J. K. Roosevelt, H. A. Shepard, John F. Skirrow, E. B. Tuttle, E. A. Wolff, C. A. Wright.

EDUCATION

Harold Pender, Chairman, University of Pennsylvania, Philadelphia, Pa.
C. A. Adams, Bion J. Arnold, Edward Bennett, Gano Dunn, W. C. L. Eglin, C. E. Eveleth, D. C. Jackson, F. B. Jewett, Farley Osgood, Harold B. Smith, R. W. Sorensen, J. B. Whitehead, W. R. Whitney, W. E. Wickenden.

ELECTRICAL MACHINERY

H. M. Hobart, Chairman, General Electric Co., Schenectady, N. Y.
J. C. Parker, Vice-Chairman, Brooklyn, N. Y.
C. A. Adams, H. C. Albrecht, B. F. Bailey, B. L. Barns, B. A. Behrend, A. C. Bunker, James Burke, Walter M. Dann, L. L. Elden, G. Faccioli, W. J. Foster, Harold Goodwin, Jr., J. I. Hull, V. Karapetoff, A. H. Kehoe, A. E. Kennelly, P. M. Lincoln, A. M. MacCutcheon, F. D. Newbury, N. L. Pollard, R. F. Schuchardt, C. E. Skinner, A. Still, R. B. Williamson.

ELECTROCHEMISTRY AND ELECTROMETALLURGY

G. W. Vinal, Chairman, Bureau of Standards, Washington, D. C.
Lawrence Addicks, Arthur N. Anderson, T. C. Atchison, Farley G. Clark, Safford K. Colby, F. A. J. Fitzgerald, W. F. Hendry, Walter E. Holland, F. A. Lidbury, Wm. A. Moore, Charles H. Moritz, Carl G. Schluederberg, Magnus Unger, J. B. Whitehead, J. L. Woodbridge, J. L. McK. Yardley.

ELECTROPHYSICS

J. H. Morecroft, Chairman, Columbia University, New York
V. Bush, R. E. Doherty, Herbert Bristol Dwight, Charles Fortescue, V. Karapetoff, A. E. Kennelly, W. B. Kouwenhoven, R. A. Millikan, F. W. Peek, Jr., Harold Pender, Chester W. Rice, J. Slepian, Harold B. Smith, J. B. Whitehead.

INSTRUMENTS AND MEASUREMENTS

A. E. Knowlton, Chairman, Dunham Laboratory, Yale University, New Haven, Conn.
F. V. Magalhaes, Vice-Chairman
H. B. Brooks, Secretary
O. J. Bliss, Perry A. Borden, W. M. Bradshaw, J. R. Craighead, W. A. Del Mar, E. D. Doyle, W. M. Goodwin, Jr., C. M. Jansky, Jr., W. B Kouwenhoven, P. M. Lincoln, W. M. McConahey, W. J. Mowbray, H. A. Perkins, L. T. Robinson, Bryon W. St. Clair, G. A. Sawin, I. B. Smith, Roy Wilkins.

APPLICATIONS TO IRON AND STEEL PRODUCTION

F. B. Crosby, Chairman, Morgan Construction Co., 15 Belmont St., Worcester, Mass.
A. C. Cummins, W. C. Kennedy, A. G. Pierce, A. G. Place, F. O. Schnure, G. E. Stoltz, J. D. Wright.

PRODUCTION AND APPLICATION OF LIGHT

Preston S. Millar, Chairman, Electrical Testing Laboratories, 80th St. & East End Ave., New York
W. T. Blackwell, J. M. Bryant, W. T. Dempsey, H. W. Eales, F. M. Feiker, F. F. Fowle, G. C. Hall, H. H. Higbie, A. S. McAllister, G. S. Merrill, F. H. Murphy, Charles F. Scott, B. E. Shackelford, C. J. Stahl, G. H. Stickney.

APPLICATIONS TO MARINE WORK

L. C. Brooks, Chairman, Bethlehem Shipbuilding Corp., Quincy, Mass.
H. F. Harvey, Jr., Vice-Chairman
J. S. Jones, Secretary
R. A. Beekman, J. F. Clinton, C. S. Gillette, William Hetherington, Jr. H. L. Hibbard, Edward C. Jones, A. Kennedy, Jr., M. A. Libbey, E. B. Merriam, W. F. Meschenmoser, I. H. Osborne, Arthur Parker, G. A. Pierce, H. M. Southgate, W. E. Thau, C. P. Turner, A. E. Waller, J. L. Wilson, R. L. Witham.

APPLICATIONS TO MINING WORK

F. L. Stone, Chairman, General Electric Co., Schenectady, N. Y.
W. C. Adams, M. C. Benedict, Graham Bright, H. W. Eales, L. C. Ilsley, G. M. Kennedy, R. L. Kingsland, A. B. Kiser, Carl Lee, W. H. Lesser, John A. Malady, Charles H. Matthews, D. C. McKeehan, W. F. Schwedes, W. A. Thomas, C. D. Woodward.

GENERAL POWER APPLICATIONS

A. M. MacCutcheon, Chairman, Reliance Electric Engineering Co., 1088 Ivanhoe Road, Cleveland, Ohio
P. H. Adams, D. H. Braymer, H. E. Bussey, R. F. Chamberlain, C. W. Drake, E. W. Henderson, H. D. James, P. C. Jones, J. C. Kositzky, A. C. Lanier, W. S. Maddocks, N. L. Mortensen, H. W. Rogers, H. L. Smith, W. H. Timbie, W. K. Vanderpoel, A. E. Waller, W. C. Yates.

POWER GENERATION

Vern E. Alden, Chairman, Consolidated Gas & Electric Company, Baltimore, Md.
H. A. Barre, E. T. Brandon, H. W. Eales, Louis Elliott, N. E. Funk, C. F. Hirshfeld, Francis Hodgkinson, P. Junkersfeld, H. A. Kidder, J. T. Lawson, W. H. Lawrence, James Lyman, W. E. Mitchell, I. E. Moultrop, J. C. Parker, M. M. Samuels, F. A. Scheffler, R. F. Schuchardt, A. R. Smith, Nicholas Stahl, W. M. White.

POWER TRANSMISSION AND DISTRIBUTION

P. H. Thomas, Chairman, 120 Broadway, New York
P. H. Chase, Vice-Chairman, Philadelphia, Pa.
R. N. Conwell, Vice-Chairman, Newark, N. J.
F. M. Farmer, Secretary, 80th St. & East End Ave., New York

DIGEST OF CURRENT INDUSTRIAL NEWS

NEW CATALOGUES AND OTHER PUBLICATIONS

Mailed to interested readers by issuing companies.

Motors.—Bulletin 137, 12 pp. Describes Wagner wound-rotor, slip-ring, polyphase motors. Wagner Electric Corporation, St. Louis, Mo.

Circuit Breakers.—Bulletin 9000, 12 pp. Describes Pacific multi-break oil circuit breakers. Pacific Electric & Manufacturing Company, 5815 Third Street, San Francisco, Cal.

Transformers.—Bulletin 2050, 4 pp. Describes Pittsburgh polyphase transformers, and discusses the importance of low exciting current and its value in the operation of transformers. Pittsburgh Transformer Company, Columbus & Preble Avenues, Pittsburgh, Pa.

Outdoor Substations.—The December 15 issue of the "Delta-Star Monthly," published by the Delta Star Electric Company, 2400 Block Fulton Street, Chicago, contains an interesting description of a standard outdoor substation construction for voltages up to 132 kv.

Electrical Drives for Power Plant Auxiliaries.—Bulletin 7381, 24 pp. Describes the advantages of motor driven power plant auxiliaries, including pumps, fans and blowers, coal handling equipment, pulverized fuel equipment, etc. Westinghouse Electric & Mfg. Company, East Pittsburgh, Pa.

Illuminating and Wiring Equipment.—Catalog 24, 182 pp. Describes Benjamin electrical products, which include reflector-sockets, outdoor lighting fixtures, store and office lighting equipment, industrial signals, wiring devices, etc., Benjamin Electric Manufacturing Company, 120 So. Sangamon Street, Chicago, Ill.

Block Signals On a Steam Railway.—Bulletin 146, 100 pp., entitled "Alternating Current Signals on the Southern." The installation described covers 667 continuous miles of double track and presents a good example of the applicability of this type of signal system on a steam railroad where average track conditions prevail. General Railway Signal Company, Rochester, N. Y.

General Electric Catalog No. 6001 B.—Supersedes all previous catalogs issued by the company, except those dealing with railway, mine and industrial supplies and merchandise products. This complete catalog is issued every two years. The book is two inches thick and contains more than 1100 pages, the illustrations total more than 3200. The catalog is thumb-indexed into sixteen sections, as follows: Generation, wire and cable, distribution transformers, arresters, voltage regulators, switchboards and accessories, meters and instruments, motors, motor applications, industrial control, railway, lighting, industrial heating, miscellaneous and indexes.

NOTES OF INDUSTRY

Union Electric Manufacturing Company, Milwaukee, Wis., manufacturers of electric motor control equipment, announce the opening of a New York office in the Hudson Terminal Building, 30 Church Street, under the direction of A. J. Heidt.

Simplex Wire & Cable Company, Boston, Mass., has opened a branch office in the Lew Building, St. Augustine, Fla., in order to better care for the steadily increasing volume of business in this state. F. H. Pettee, who has represented the company in Florida for a number of years will be manager of the new office.

The Gray Instrument Company, 64 W. Johnson St., Germantown, Philadelphia, has been organized by J. G. Gray, formerly president of Queen & Company, Inc., and Queen-Gray Company. The new company will continue the manufacture of the line of electrical measuring and scientific instruments made for many years by the above named companies.

The J. G. White Engineering Corporation, New York, which has a contract with the Firestone Plantations Company to construct a harbor, breakwater, wharves, roads, etc., for the Government of Liberia at Monrovia, West Africa, recently sent a construction organization via England on the steamship President Roosevelt. Plant, tools, equipment and all necessary supplies also went forward on the same day, via the steamship West Humhaw, sailing direct to Monrovia.

Electrification of Chilean Mines.—The Andes Copper Company and the Chilean Exploration Company, both of Chile, have placed with the Westinghouse Electric & Manufacturing Company, orders totalling twenty-three industrial electric locomotives for the purpose of inaugurating the electrification of the haulage systems of these two mining properties. The complete electrification eventually will require some fifty additional 70-ton locomotives. The electric power for the haulage system at the Chile Exploration Company is generated by steam turbines and oil fired boilers located at the seacoast seventy-five miles away, and transmitted to the mining property at 110,000 volts.

General Electric Company Secures Manufacturing Site in St. Louis.—Gerard Swope, President of the General Electric Company, has announced that the company has definitely decided to purchase a site for a manufacturing establishment in the City of St. Louis. The tracts of real estate selected contain in the aggregate about 155 acres, of which all but 11 acres are within the city limits of St. Louis; the balance lies just beyond the city limits in St. Louis County. The property in general lies between the Belt Line of the Terminal Railroad Association and Goodfellow Avenue. It also has a frontage on Bircher Avenue.

Increase in Foreign Trade During 1925.—The Director of the Bureau of Foreign and Domestic Commerce reports that the export trade of the United States during 1925 continued its steady advance, exceeding by more than 7% its value in 1924. The total value of our exports for the year is in the neighborhood of $4,900,000,000, the largest figure since 1920. British exports of domestic products were slightly less than in 1924, and French exports also showed a decline. Those of Germany increased about 6%.

Exports of electrical machinery, in contrast with the normal increase in recent years, have been stationary. The increase of recent years in exports of copper was continued during 1925.

Buffalo General Electric Company Expands.—The rapidly increasing load supplied by the Niagara system, and the necessity of maintaining a proper balance in the supply of steam and hydro-power have made it necessary to add a 60,000 kw. turbine to the equipment of the River Station of the Buffalo General Electric Company. The construction schedule calls for the new unit to be in operation early in the fall of 1926. The River Station at present includes three 20,000 kw. and one 35,000 kw. turbine generators. These, as well as the new unit now to be added, are of General Electric manufacture.

Western Electric Creates New Company.—The electrical supply business carried on by the Western Electric Company has been set apart from the telephone manufacturing business and incorporated under the name of Graybar Electric Company. The Western Electric Company has been both the manufacturing company of the Bell System and a distributor of electrical supplies. Both of these lines of business require specialized organization and specialized management. The rapid expansion of the supply department made an entirely separate corporate identity even more necessary.

The new company is capitalized at $15,000,000, all owned by the Western Electric Company. The officers are as follows: Charles G. DuBois, president of the Western Electric Company, is chairman of the Board; Albert L. Salt, president; Frank A. Ketcham, George E. Cullinan, Leo M. Dunn and Howard A. Halligan, vice-presidents; Richard H. Gregory, comptroller.

The Invisible Service of Science

Service of Science reminds us first of the visible service of science, which one can see in every nook and corner of our daily life. But there is an invisible service of science which has a purely intellectual, esthetic, and spiritual value. This is the service to which I wish to call attention. In this connection it is well to point out at this very outset that during the last three hundred years, since the pilgrim fathers landed at Plymouth rock, science has revealed three distinct physical realities. The first physical reality was revealed through the science of matter in motion; the second, through the science of electricity in motion; and the third, through the science of energy in motion. Each one of these contributes a service which is not visible in every nook and corner of our daily life; but it has an intellectual as well as an esthetic and spiritual value.

1. The Science of Matter in Motion

The first physical reality revealed by the science of matter in motion announced its approach three hundred years ago, when Galileo discovered the concept of acceleration and its relation to the moving force. A hundred years later Newton finished the work which Galileo had commenced; he placed the crowning dome upon the beautiful intellectual structure the foundation of which had been laid by Galileo. The Galileo-Newton science of matter in motion, the science of dynamics, is this intellectual structure. It revealed the first physical reality which is our earliest scientific knowledge of the material unvierse. Nothing exhibits the beauty of this reality so well as the motion of the planets around the sun. Here we have a cosmic system of bodies, in whch each part moves along a definite path with a precision unattainable in any mechanism constructed by the hand of man. And yet the only guiding force in this perfect order is the gravitational action of matter, operating according to laws of childlike simplicity. Michelangelo, we know, rendered immortal service to the intellectual as well as to the esthetic and spiritual activity of the human soul, when he impressed his genius upon that magnificent edifice on the Vatican Hill, St. Peter's basilica in Rome. Newton, the Michelangelo of the science of dynamics, rendered to mankind a similar, but immeasurably greater service when through his science he gave a new meaning to the most sublime edifice known to man, to the starry vault of heaven.

2. Science of Electricity in Motion

The second physical reality revealed itself through the science of electricity in motion. Among those who laid the foundation to this physical reality Faraday must be mentioned first. He discovered the meaning of acceleration in electrical motions; he is the Galileo of the Electrical science. But who is its Newton? Sixty years ago Maxwell spoke like a prophet when he made the startling announcement that radiation of light and heat is a manifestation of moving electricity. The prophecy came true and Maxwell rose to the lofty position of a Newton of electrical science. Its achievements during the last sixty years are the fruits of our efforts to find a complete interpretation of Maxwell's prophecy. The greatest among them is the discovery that the origin of all radiation is in the motions of the tiny electrons which are, as far as we know today, the immutable primordial building stones of the material universe. Atoms have been revealed to us as complex structures, made up of positive and negative electrons, the unchangeable granules of that subtle substance which we call electricity. Everything that moves and has its being in this boundless universe seems to be deriving its breath of existence from the electrical forces which have their origin in the tiny electrons. The combined activities of these infinitely small but infinitely numerous workers is the activity of that stupendous unit, called the universe. The book of Genesis, composed by a Moses of modern science, would probably start as follows:

In the beginning God said: Let electricity move, and the embryo of the universe began to form.

If the contemplation of this physical reality does not uplift the soul of man and stimulate its intellectual and esthetic as well as its spiritual activity then St. Paul was in error when he said: "We all with open face beholding the glory of the Lord are changed into the same image from glory to glory . . . . ."

3. The Science of Radient Energy in Motion

These two physical realities prepared the human mind for a third physical reality which is being revealed to us through the motion of cosmic, that is of radiant, energy. The concept of energy is a comparatively new concept, and its full meaning dawned upon us less than a hundred years ago. Today we know that the background of every physical phenomenon is a transformation of some form of energy. We also know that

*Address delivered on January 8th before the Pittsburgh Section of the A. I. E. E.

the total energy content in the universe is constant, but that its radiated parts are wandering through space, as if in search of new opportunities for benevolent service. Each visible star radiates its energy to other stars, and our little terrestrial globe would be a sad and barren abode if it did not float in the life-giving energy stream of solar radiation.

This radiation proceeds from countless tiny electronic centers, each one of them attending strictly to its own activity and paying no attention to the activity of its neighbors. It is, therefore, a chaotic activity of an immense number of essentially autonomous workers. Hence solar radiation is a most chaotic swarm of countless energy units, and yet their service on earth shows that beautiful order which is the fairest adornment of our terrestrial globe. Just watch the clouds of the summer sky, moving, like Milton's heavenly host, in stately procession, and carrying relief to the thirsty continent. Remember, then, that the power behind this gigantic labor of beautifully ordered service is the chaotic energy stream of solar radiation. Here is a transformation of a chaos into a cosmos, a revelation of a new physical reality, which gives a concrete meaning to the belief of ancient Greece, that the creation of the world is a transformation of a chaos into a cosmos. A new science is rising in the background of this physical reality. Its foundation was laid a hundred years ago by that great savant, Sadi Carnot, who is its Galileo. But who is its Newton? Not only has he not yet appeared but the science has not yet received its appropriate name. I call it, for want of a better name, The Science of Coordination.

Carnot told us how the chaotic molecular activity, called heat, can be transformed into orderly service by interposing a heat engine in the path of heat in its passage from a higher to a lower temperature. The engine is a guide, a coordinator, of the chaotic heat energy. Similarly a galvanic cell is a coordinator of chemical activity which is chaotic when unguided. The caloric engine and the galvanic cell are coordinators invented by man. Their guiding operation is performed in accordance with the designing intelligence of man who has a definite purpose in view. But what is the coordinator which transforms the chaotic solar energy, absorbed by the leaf of a plant, into a coordinated service which manifests itself in the orderly growth of the plant? Each organic cell as a whole and all of its miscroscopic and ultra microscopic components feed, grow, and divide in an orderly way; they transform chemical activity, which is chaotic when unguided, into orderly work and service. Is there a guiding coordinator attached to each one of these tiny organic units, and, if there is, does it operate in accordance with some intelligent design and purpose as is the case in the caloric engine and the galvanic cell? What function, if any, does the recently revealed radiation of marvellous penetrability play in the physico-chemical processes of the organic cells? One cannot resist the temptation of asking this question, because it suggests the possibility of finding a new relationship between some new cosmic processes going on near the very boundaries of our stellar system and the tiny living cells on earth. Some future Newton will answer all these questions; in the meantime the contemplation of the physical reality of which these questions are a part cannot fail to furnish that intellectual, esthetic, and spiritual exhilaration which is the noblest service of science to the human soul.

M. I. PUPIN.

Some Leaders of the A. I. E. E.

Dugald C. Jackson, the twenty-third president of the A. I. E. E., was born at Kennett Square, Pa., February 13, 1865. He was graduated from Pennsylvania State College in 1885 with the degree of B. S., receiving the degree of C. E. from the same college in the year 1888. Following graduation, Mr. Jackson devoted two years to post graduate work in electrical engineering at Cornell University, serving as instructor in physics in 1887.

For two years he was vice-president and engineer of the Western Engineering Company, at Lincoln, Neb., and throughout the years 1889-1890 served as assistant chief engineer with the Sprague Electric Railway and Motor Company, at New York. Following this, for one year, he was chief engineer of the central district of the Edison General Electric Company.

In the year 1891, Mr. Jackson became a member of the faculty of the University of Wisconsin. During the sixteen years of his engagement there the department of Electrical Engineering of the University was developed.

Since the year 1907 Professor Jackson has been at the head of the Department of Electrical Engineering at Massachusetts Institute of Technology. He was senior member of the firm of D. C. and W. B. Jackson, consulting engineers, for twenty years, during which time the company was actively identified with many of the noteworthy electrical projects of the country. At the time the British telephone systems were taken over by the British Government, he served it as consulting engineer.

In the World War, Professor Jackson served overseas as Lieut.-Colonel of Engineers, rendering distinguished service to the American Expeditionary Forces.

Professor Jackson was a member of the Jury of Electrical Awards at the World's Columbian Exposition, Chicago, 1893, and at the Pan-American Exposition, Buffalo, 1901. He is a Chevalier of the Legion of Honor, France; was president of the A. I. E. E. throughout the term 1910-11; president of the Society for Promotion of Engineering Education, 1905-06, and a member of various other American and foreign technical and scientific societies.

He is the inventor of a number of electrical devices as well as author of many technical papers and books.

Cipher Printing Telegraph Systems

For Secret Wire and Radio Telegraphic Communications

BY G. S. VERNAM[1]

Associate, A. I. E. E.

Synopsis.—*This paper describes a printing telegraph cipher system developed during the World War for the use of the Signal Corps, U. S. Army. This system is so designed that the messages are in secret form from the time they leave the sender until they are deciphered automatically at the office of the addressee. If copied while en route, the messages cannot be deciphered by an enemy, even though he has full knowledge of the methods and apparatus used. The operation of the equipment is described, as well as the method of using it for sending messages by wire, mail or radio.*

The paper also discusses the practical impossibility of preventing the copying of messages, as by wire tapping, and the relative advantages of various codes and ciphers as regards speed, accuracy and the secrecy of their messages.

* * * * *

Introduction

The purpose of this paper is to discuss briefly certain methods for obtaining secrecy in connection with messages sent by wire or radio telegraphy, and to describe in particular printing telegraph cipher systems that were developed for this purpose during the World War.

The desirability of obtaining secrecy in telegraphic communications and the possible advantages of a system that would be capable of sending messages in such form as to be entirely secret, and which at the same time, would be more rapid and accurate than the codes and ciphers ordinarily used, were brought out in conversations with officers of the Signal Corps, U. S. Army. These discussions made it evident to the engineers of the Bell System that it would be very helpful if the well-known automatic features of the printing telegraph art could be made available for enciphering and deciphering telegraph messages, and could at the same time be made practical for use under service conditions.

The engineers recognized that printing telegraphs[2] were rapid and accurate, but were not secret except to the extent that their signals could not be read from a telegraph sounder. With the general requirements for secrecy systems in mind, studies were made of printing telegraph systems to determine how their messages could be made secret. The result of this work was the development of a cipher system that is capable of rendering messages entirely secret, is rapid and accurate, and is practical to use.

This "Cipher Printing Telegraph System" was called to the attention of the Signal Corps. The Signal Corps became very much interested, tested the secrecy of communications handled by the system and tried it out between New York and Washington. This trial proved that the system could be successfully used to send messages secretly and at a speed many times faster than by methods previously in use.[3]

Each message is automatically enciphered at the sending station and deciphered in the same manner at the receiving station. The method of ciphering will be described later in this paper and is such that under certain conditions of use, the messages are rendered entirely secret, and are impossible to analyze without the key, even if it is assumed that the enemy can capture a machine, learn its method of operation in all details, and intercept a large number of messages.

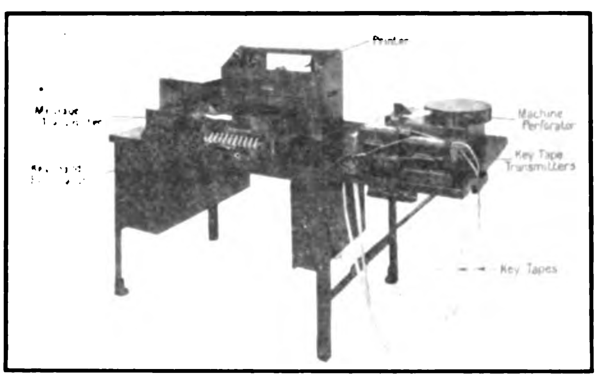

Fig. 1—Cipher Printing Telegraph Machine

Flexibility of System

This method of ciphering can be used with machines of various types. The electrically-driven machine shown in Fig. 1 was developed during the war particularly for the Signal Corps, U. S. Army. In order to save time in production, standard printing telegraph parts were used wherever possible with the result that this machine has the appearance of a "start-stop" printing telegraph set with some additional units mounted on a shelf at the right end of the table. This type of cipher set is particularly suitable for handling large amounts of traffic at high speed.

To be presented at the Midwinter Convention of the A. I. E. E., New York, Feb. 8-11, 1926.

3. Note: See page 140, "Report of the Chief Signal Officer to the Secretary of War" for the year ending June 30, 1919.

If something smaller in size and portable is required, the machine shown in Fig. 2 may be used. This machine is light and strictly portable as no electric current is required for its operation. It is slower than the large machine and requires a knowledge of the standard "Baudot" printer code (see Fig. 8) on the part of the operator, but its messages are equally secret.

These machines are considered suitable for general use by government departments, business concerns,

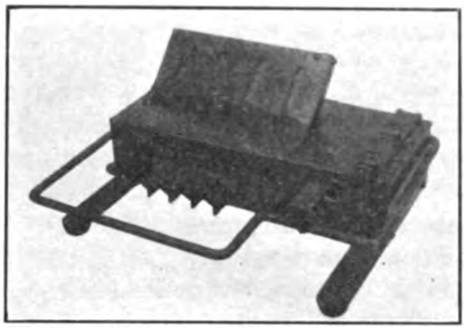

FIG. 2—PORTABLE CIPHER MACHINE

etc., for handling confidential messages rapidly and secretly. The method of using them can be varied to suit conditions and so as to make unauthorized decipherment as difficult as may be necessary up to the point where it becomes impossible even for an expert cryptanalyst.

If an appreciable demand exists for machines of special sizes or having particular operating features for special uses, these can be built to employ the same secrecy principle. For example, the functions of ciphering and transmitting over a telegraph circuit can be combined in one machine, if desired, so that, at the sending station, messages can be simultaneously enciphered and transmitted over the telegraph circuit, and so that, at the receiving station, messages can be received, deciphered automatically and printed directly in plain text; thus avoiding the slight delay caused by separately enciphering and deciphering each message.

FIG. 3—SAMPLE CIPHER MESSAGE IN PRINTED FORM

This method is particularly suitable for cases where the cipher equipment can be directly connected to a telegraph line or to a radio transmitter and receiver and can be operated by the same personnel.

If the cipher messages are to be turned over to a telegraph or cable company to transmit, they should be in written or printed form. For this purpose, the cipher machine can be arranged to print the cipher messages in groups of five letters each, spaced to form "words." Fig. 3 is a copy of such a message shown exactly as it was prepared by the cipher set. Such messages can be printed by the machine directly on the telegram blank with the address and signature in plain English, and if desired, a carbon copy can be made at the same time for record purposes.

PREVENTING ACCESS TO MESSAGES

There appear to be two general methods for securing secrecy in connection with communications, namely, (1) by preventing or at least attempting to prevent access to the messages or to the lines of communication and, in the case of telegraphic communications by rendering the lines incapable of being tapped, and (2) by the use of codes and ciphers with key systems known only to the proper parties.

As regards wire tapping, sensitive alarm devices arranged to operate on small changes in the electrical constants of the line circuit, are unsuccessful as a means of preventing unauthorized parties from obtaining access to the circuit. The electrical condition of a long telegraph circuit is continually changing as a result of variation in temperature and other weather conditions. This fact limits the useful sensitivity of any such alarm devices, whereas by using vacuum tube amplifiers, a record of the signals passing over a circuit can be obtained without appreciably disturbing the line circuit and even without actual contact with the wire.

Telegraph systems have been invented, that will operate successfully on very small line currents, and which use coils and condensers to suppress the harmonics in the signal impulses, or in other words to avoid sudden changes in current value. The currents induced in neighboring circuits by such a system would be small, so that it would be rather difficult, if ordinary methods are used, to obtain a record of the signals by their inductive effect. This can be readily done, however, if modern vacuum tube amplifying equipment is used. It is also obvious that a record can be easily obtained if the wire is tapped.

Many attempts have been made to obtain secrecy during the actual transmission of telegraph messages by making them unintelligible. In one system of this sort, successive signal impulses are sent alternately over two line wires by means of a rotary switch which puts the sending key in connection first with one wire and then with the other at each movement of the key. At the receiving end, the impulses are combined through one relay. With this system, the messages may be readily copied if both wires are tapped, and it is quite possible to decipher the messages even if only one wire is tapped.

Proposals have also been made to use complex devices or methods, or so to mutilate the normal impulses that they become unintelligible to anyone tapping the line circuit or intercepting the signals if sent

by radio. Any secrecy system of this general class can be readily "broken" by anyone having a knowledge of the methods used and the ability to assemble and operate the necessary apparatus.

Tapping Duplex and Multiplex Circuits

It has also been considered that a full duplex circuit or a multiplex printer circuit, in which messages are being transmitted simultaneously in opposite directions, could not be tapped and that circuits of this character insured secrecy to the communications thus being handled. This is not true, however, and means have been invented by which a message originating at one station of an ordinary duplex circuit can be tapped at any part of the circuit, even though a second message is also going over the same circuit simultaneously in the opposite direction. This means that a multiplex printer circuit, in which as many as eight messages, four in each direction, are handled simultaneously, may be tapped and a person who is familiar with the system can readily analyze the multiplex impulses to distinguish between adjacent channels and the letters of each message in each channel.

An arrangement for tapping a duplex circuit is shown in Fig. 4. A single sensitive polar relay may be used to receive the signals from either end of the circuit, or by using two such relays, the signals in both directions may be read simultaneously. Each relay may control a sounder or a suitable recording device. One winding of each relay is connected in series with the line, the other winding being connected in a circuit from line to ground through an "artificial line" composed of adjustable resistances and con-

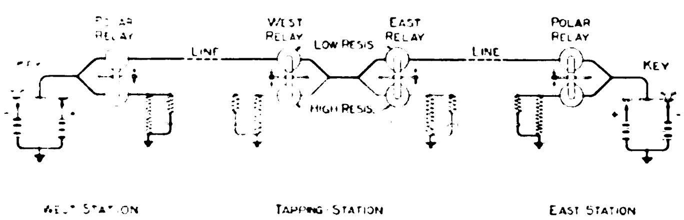

Fig. 4—Method of Tapping a Duplexed Line

densers. The line winding of each relay should have relatively few turns and should be of low resistance, the other winding having a large number of turns. Each artificial line should be adjusted to be substantially equivalent to the impedance of the corresponding section of line including that of the terminal station equipment multiplied by the ratio of turns of the relay windings.

Signals transmitted from the west station will pass through the line windings of both relays at the tapping station, a small part of the signal currents also going through the lower windings and artificial lines to ground. The signal currents pass through both windings of the west relay in series, the magnetic effects of the two windings aiding each other, so that the armature of this relay will follow the signals. The same signals pass through both windings of the east relay in parallel, the magnetic effects opposing and balancing so that this relay does not respond to signals from the west station.

In a similar manner, signals from the east terminal station will energize the east relay but not the west relay at the intermediate station, so that by using suitable recording devices associated with each relay, a copy of signals in both directions may be obtained.

Tapping a Multiplex Circuit

This method may be used to tap a multiplex printer circuit, in which case a tape record of the form shown in Fig. 5 will be obtained. If this is taken from a

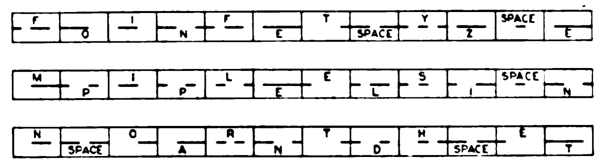

Fig. 5—Tape Record of Multiplex Printer Signals

"double-duplex" circuit alternate letters must be read as indicated, to get the message from either channel. Every third or every fourth letter must be chosen if the circuit is operated by the "triple-duplex" or "quadruple-duplex" method. The individual letters are in the ordinary five-unit printer code, the polarities of alternate signals being reversed. To decipher such a tape, it should be divided into units of five dot lengths each. The correct starting point can be found in not more than five trials and can be recognized by the fact that the letters of each message then form sensible combinations.

Codes and Ciphers

Secrecy, in connection with telegraphic communications, is usually obtained at the present time by means of codes and ciphers, the term "code" being applied in cryptography to the method in which entire words, or phrases of a message are replaced by arbitrary groups of letters or numbers usually printed in a code book, identical copies being kept by those using the code, "cipher" referring usually to a system in which the individual letters of a message undergo a change either in arrangement or nature.

It is obvious that the combinations of letters in a cipher message will not form pronounceable groups or genuine words except occasionally by accident, but "code" systems can be arranged to use pronounceable artificial "words" or actual dictionary words, if desired. This is usually done, as such "code words" are handled by the telegraph and cable companies at a cheaper rate than the unpronounceable so called cipher "words."

Each of these two general systems has advantages and disadvantages which cause them to be used for

certain classes of work, depending upon the conditions. The code system has the outstanding advantage, especially for commercial work, of enabling messages to be shortened so that the tolls are reduced, and it is chiefly for this reason that commercial codes are used. Code is not very accurate, as a mistake in a single code group or even a single letter may change the meaning of an entire message, or necessitate its repetition. If secrecy is required, it is necessary to use carefully guarded private code books, the maintenance of secrecy and accuracy during the printing and distribution of which may cause great trouble. Such books must be carefully used to maintain secrecy, and must be immediately replaced, sometimes at great expense and inconvenience if they should become compromised.

Ciphers, in general, are slower than codes unless machines are used, but then they may be very much faster. They are more accurate, and depending on the system used, cipher messages may be more or less secret than code messages.

There are two general classes of ciphers, known respectively as transposition ciphers and substitution ciphers. In the first class, as the name suggests, the letters of the original message are rearranged, according to a definite system, and in the second class, substitutions for the original letters are made according to some prearranged key. In one, the relative positions of the letters are changed and in the other, the letters themselves.

Transposition Ciphers

A transposition cipher may be distinguished from a substitution cipher by a study of the frequency of occurrence of the letters of the message by comparison with a frequency table of the language of the original message. Studies which we have made of the frequency of the different letters of the English language as they occur in telegrams sent over our private wires, indicate that they are used about as shown in Fig. 6. It is apparent that some letters are used very frequently, the vowels a, e, i, o, u, forming approximately 40 per cent. of the total, e being the most commonly used letter of all. [4]This chart is similar to those used by cipher experts.

In a transposition cipher the letters must be rearranged according to a definite system known to the receiving correspondent. Those who make a study of ciphers tell us that such systems are usually easy to discover, particularly if a considerable number of messages are intercepted including two or more of exactly the same length. Transposition ciphers are not suitable for use with machines.

Substitution Ciphers

In substitution ciphers the order of the letters remains unchanged, but for each letter is substituted its equivalent in one or more cipher alphabets. For example, using the table below, for each letter in the plain text alphabet we may substitute its equivalent in the cipher alphabet. To decipher, this process is reversed.

Plain Text–A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

Cipher –F Q R U K A H G Z S E M L Y P O B C J V D T X W N I

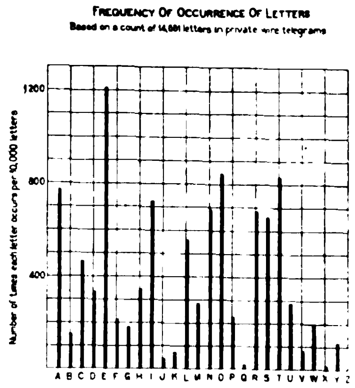

Fig. 6

If a chart is prepared from a frequency count of the letters in such a cipher message, it will have the general appearance of Fig. 6 but the crests will correspond to different letters. Messages of this type are readily deciphered by an expert even when a "mixed" alphabet

Fig. 7

is used, such as that illustrated above in which the letters of the cipher alphabet are not in the usual alphabetic order.

By using more than one alphabet, the cipher may be made more difficult to "break." The method may

4. See "Manual for the Solution of Military Ciphers" by Lt. Col. Parker Hitt.

be described by referring to the "cipher square" shown in Fig. 7. In this table, the top alphabet represents the plain text, whi e below it are shown 26 cipher alphabets, each designated by a "key" letter given in the left-hand column. Some form of key, usually a word, is used, the letters of this key word designating the alphabets and the order in which they are to be used. A different cipher alphabet is used in a repeating manner, with each successive letter of the message.

This type of cipher may be distinguished by the fact that the frequency chart is rather flat, the frequency of occurrence of all letters being roughly the same. Each cipher alphabet is used repeatedly at regular intervals. By first finding this interval and then studying each alphabet separately, messages of this type can be deciphered readily by an expert.

Running Key Ciphers

If the key used with this type of cipher is made very long, so that it never repeats and if any portion of this key is never used for more than one message, the operation of "breaking" the cipher becomes very much more difficult. If, now, instead of using English words or sentences, we employ a key composed of letters selected absolutely at random, a cipher system is produced which is absolutely unbreakable.

This method, if carried out manually, s slow and laborious and liable to errors. If errors occur, such as the omission of one or more letters, the messages are difficult for the recipient to decipher. Certain difficulties would also be involved in preparing, copying and guarding the long random keys. The difficulties with this system are such as to make it unsuitable for general use, unless mechanical methods are used.

Cipher Printing Telegraph System

By using machine methods, this type of cipher may be made practicable for use. Fig. 1 is an illustration of the cipher machine previously referred to, and which operates on this principle. As previously mentioned, this machine was developed during the recent war and adopted by the Signal Corps, U. S. Army.

Certain parts of this machine are the same as those used for ordinary printing telegraphs, such as those described in recent papers before the Institute. For this reason, it will not be necessary to describe in detail the parts which are commonly used in such systems, such as the keyboard perforator, the transmitters, and printer.

Cipher Machine—Method of Operation

The messages are first punched in a paper tape by means of the keyboard perforator. The code used is shown in Fig. 8. This is the well-known five-unit printing telegraph code. Each letter is represented by a small feed hole and one or more larger holes which may be punched in five different positions across the tape. Since n each of these five positions a hole may or may not be punched, there are $(2)^5$ or 32 possible different combinations in this code of which 26 are used to designate letters, the other 6 representing the so-called "stunts," which are the "space," "carriage return," "line feed," "figure shift," "letter shift," and the "blank" or "idle" signal.

The cipher "key" may take the form of another tape of similar form having characters punched in it at random and with every tenth character numbered, so that the tape may be set to any designated starting position. The key tapes are prepared in advance, the original key being perforated by hand, as by working

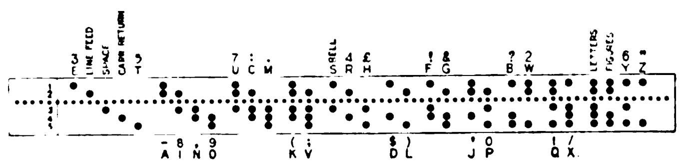

Fig. 8—Tape Showing Printing Telegraphic Code

the keyboard at random, additional copies being made automatically by the machine.

The message tape is passed through a unit known as a transmitter, where the holes in the tape serve to control the positions of five contact levers, each of which makes contact with either of two bus-bars. The key tape controls the contacts of a second tape transmitter. The contacts of the two transmitters are connected to a set of five magnets or relays as shown in Fig. 9. Each magnet wil be energized if the correspondingly numbered contacts of the two transmitters are against opposite bus-bars, but not if they are making contact with similar bus-bars. In the diagram, contacts 1 and 2 of the message transmitter, are against the left or positive bus-bar, this setting representing the letter *A*. Contacts 1, 4 and 5 of the key transmitter are against the positive bus-bar, representing the letter *B* in the printer code. This will energize magnets 2, 4 and 5, which combination represents the letter *G*.

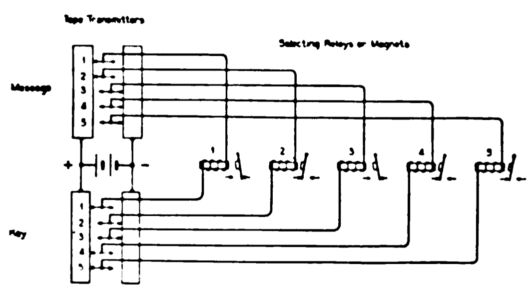

Fig. 9

All of the possible combinations resulting from various characters in the two tapes might be shown in a cipher square similar to that of Fig. 7 except that it would have 32 characters on a side instead of 26.

The characters of the cipher messages, formed in this

way, may be recorded as perforations in a third tape. For this purpose a "machine perforator" is used. This device is similar in many respects to a keyboard perforator and is shown in Fig. 10. The tape, from a reel on the top of the machine, passes through the punch block at the front left corner of the machine. Here it passes under a die plate and over a group of six punches, which may be forced up through the tape by the action of an electromagnetic hammer. Five of these punches are too short to be acted on directly by the hammer and are pushed through the tape only when an individual "selecting finger" is interposed between the punch and hammer. The five selecting fingers are actuated by five magnets which may be controlled by the relays shown in Fig. 9. A ratchet-operated, star-wheel feeds the tape forward after each character has been punched.

The cipher message tape prepared in this way is unintelligible in form and may be sent to the receiving station by messenger or by mail, or if desired, it may

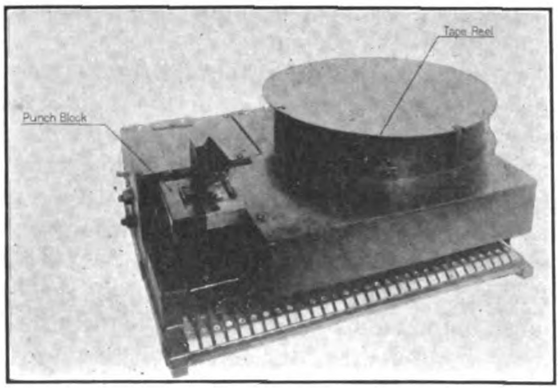

FIG. 10—MACHINE PERFORATOR

be transmitted by wire or radio and reproduced by another machine perforator at the receiving point. The cipher tape is there run through the message transmitter, where its characters combine with those of a duplicate key tape to reproduce the original message, which will be printed out in page form and in "plain text."

LENGTH OF KEY TAPE

With the system as described above, the key tape must be at least as long as the sum of all the message tapes used with it, as the messages will lose their secrecy to some extent if the key tape is used repeatedly. The use of a short repeating key may give sufficient secrecy for some uses however.

A roll of tape eight inches in diameter contains about 900 feet of tape and would serve to encipher about 18,000 words counting five printed characters and a space per word, without repeating the key. If sent at an average speed of 45 words per minute this number of words would require 400 minutes or nearly 7 hours to transmit.

In order to reduce the amount of key tape required for handling large amounts of traffic, the "double key" system was devised. In this system two key tapes are used, the ends of each tape being glued together to form a loop preferably about seven feet in circumference. The tapes should differ in length by one character or by some number which is not a factor of the number of characters in either tape. A separate transmitter is used for each tape, and the characters of the two key tapes are combined, by a method similar to that shown in Fig. 9, with those of the message tape to form the cipher message.

The result is the same as though the two key tapes were first combined to produce a long single non-repeating key, which was later combined with the message tape. This long, single key is not, strictly speaking, a purely random key throughout its length as it is made up of combinations of the two original and comparatively short key tapes. The characters in this key do not repeat in the same sequence at comparatively short regular intervals, however, as would be the case if only one key tape loop were used.

The number of characters in this equivalent single key is equal to the product of the number of characters in the two tape loops, and may easily exceed 600,000 before any part of the key begins to repeat. If proper care is taken to use the system so as to avoid giving information to the enemy regarding the lengths of the two key tape loops or their initial settings and to avoid the possibility of ever re-using any part of the resultant single key, this system is extremely difficult to break even by an expert cryptanalyst having a large number of messages and full knowledge of the construction of the machine and its method of operation.

Captain W. F. Friedman, Cryptanalyst of the Signal Corps, U. S. Army, has recently invented some modifications[5] of this system intended to eliminate the loss in secrecy that results from using the two more convenient comparatively short repeating key tapes instead of the single long non-repeating key tape. These modifications consist of changing at intervals the order of connection of the five contacts of one or more of the tape transmitters or of adding a third key tape and transmitter so arranged that the extra key tape does not step ahead in unison with the other two key tapes, but starts and stops at irregular intervals. Either of these methods, properly used, makes unauthorized decipherment practically impossible and, at the same time, does not unduly complicate the machine or its method of operation.

With the double key tape system, the handling of large volumes of traffic is greatly simplified. The tapes should be numbered so that the deciphering operator can set them at the correct starting point for each message, and rules should be adopted so that both key tapes will never be set twice at the same

5. See Patents 1,522,775 of Jan. 13, 1925 and 1,516,180 of Nov. 18, 1924.

starting point. Information regarding the proper settings for the key tapes for deciphering each message must be sent to the deciphering operator. These settings may be prearranged or they may be selected arbitrarily by the sending operator. In the latter case the numbers representing the key tape settings should be prefixed to the message. These "key indicators" should preferably be enciphered by running them through the machine together with a special key tape which is used only for this purpose.

Speed of Operation

This type of machine was operated by the Signal Corps over its private wire telegraph circuits. In service tests made by the United States Army, each outgoing message was checked by running it again through the machine to decipher and print it, and the deciphered copy was then compared with the original message, so that each message tape was run through

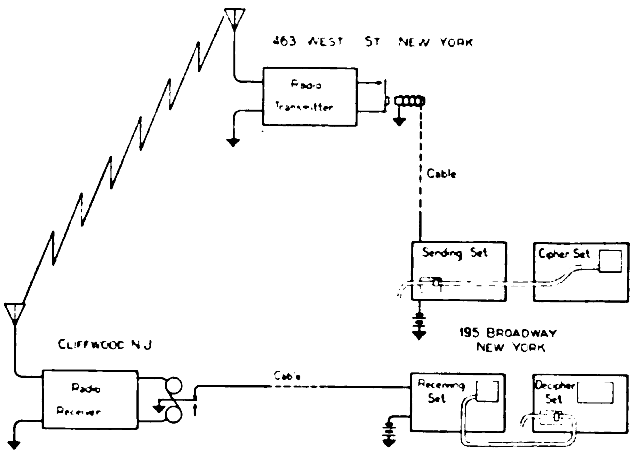

Fig. 11—Circuit for Radio Cipher Demonstrations

twice. A certain amount of time was lost, due to setting and resetting the key tapes, checking, etc., for each message, but an average enciphering speed of 10-15 words per minute was readily maintained. We understand this to be many times faster than those manual methods for enciphering or coding, which are used where a high degree of secrecy is required. Incoming messages were deciphered at the rate of 30-40 words per minute.

Operation by Radio

This cipher system was demonstrated before the delegates to the Preliminary International Communications Conference in October, 1920. During this demonstration, cipher messages were sent over a circuit containing a radio link, as illustrated in Fig. 11. The radio equipment was the same as that employed a year previous in tests on the operation of multiplex and start-stop printing telegraphs by radio and is described elsewhere.[6]

A considerable number of cipher messages was transmitted over this radio circuit during this demonstration, these messages being automatically enciphered before and deciphered after transmission, so that they they were absolutely secret, even though transmitted by radio. No interference from atmospherics or from other radio stations was noticed, all messages being received without error.

In conclusion, we wish to express our appreciation of the assistance given us by the officers of the Signal Corps and the General Staff, of the United States Army, in making tests and trials of cipher printing telegraph systems; and we wish particularly to acknowledge our indebtedness to Lt.-Col. J. O. Mauborgne, of the Signal Corps, for his advice in connection with this development and for his assistance in arranging to have tests made to determine its secrecy and demonstrations and service trials to determine its practicability for Army use. We also wish to express our appreciation of the services rendered by the Cipher Department of the Riverbank Laboratories, Geneva, Illinois, and by Col. George Fabyan, the head of these laboratories, in making tests of the secrecy of messages enciphered in various ways with these machines.

DIELECTRIC PHENOMENA

An important contribution to the study of dielectric phenomena in electric cables was made by Capt. P. Dunsheath in a recent I. E. E. paper. Developing a theory first propounded by Clerk Maxwell, the author showed how, without any hypotheses regarding the molecular structure of a dielectric, the familiar absorption effect can be explained by the lack of homogeneity of the dielectric. In such a dielectric the ratio of capacities of adjacent layers will not be identical with the inverse ratio of their resistances. The potential distribution due to the capacities will, then, differ from that due to the resistances. The latter distribution being the one obtaining when the steady state is reached, compensating capacity currents have to flow into the various condensers to adjust their potentials to the required values. The circuit for these currents consists of capacity in series with a very high resistance; they will therefore follow an exponential law and persist for a considerable time. The charging current of a cable subjected to a steady potential consists, accordingly, of three parts, the initial rush giving a potential distribution corresponding to capacity, a steady leakage current, and a transient current which gives the final potential distribution. Developing this theory, Capt. Dunsheath gave a simple explanation of the well-known V curve connecting A. C. dielectric loss with temperature, based on the negative temperature coefficient of electrolytic conductors. Although the difference between the Maxwell and the molecular theories may be purely verbal, the advantage of the former cannot be questioned, as giving a clearer insight into the electrical properties of dielectrics, and marking an advance towards the more perfect knowledge which will enable dielectric phenomena to be subjected to exact calculations.—*World Power*, December, 1925.

Supervisory Systems for Electric Power Apparatus

BY CHESTER LICHTENBERG[1]

Member, A. I. E. E.

Synopsis.—A general survey and description of the various types of supervisory systems for control and indication of remotely located electrical apparatus is given in the paper, the author first of all comparing the better known remote-control system with the supervisory system in general practise today. Description is given of the selector, distributor, audible, code-visual, synchronous-relay-visual and the carrier-current systems, the principles and features of each being discussed. The subject of telemetering is also included, together with an expression of the author's ideas of future possibilities for each of the systems above enumerated.

INTRODUCTION

SUPERVISORY systems for the control and indication of remotely located electric power apparatus can best be introduced by comparing them with the better known and more widely applied remote control systems in general application today.

The usual remote control scheme employs at least one continuous individual metallic connection between each device to be controlled and the controlling switches or keys. Supervisory systems use no individual and one, two, three or more common metallic connections between the devices to be controlled and the controlling switches or keys for as many as fifty or sixty or even more devices. Remote control systems ordinarily use control currents of the order of magnitude of one to ten amperes. Supervisory systems usually use currents of the order of magnitude of three to ten milliamperes. Remote control systems require a definite and usually very short time interval to elapse between the closing of the control switch or key and the closing of the contacts at the remote point. Supervisory systems require an appreciable and variable time to elapse between the operation of the control switch or key and the closing of the contacts at the remote point. Remote control schemes are usually designed into the electrical operating sequence of the power apparatus. Supervisory systems are invariably superimposed upon the usual sequence. Briefly, supervisory systems provide improved means for the supervision of electric power transmission and distribution.

HISTORY

Supervisory systems were developed to meet the requirements of the railway and central station industries as these expanded. The grouping of generating stations under the direction of a centrally located load dispatcher made it desirable that the dispatcher have prompt and accurate information concerning the electric power system. The widespread application of automatic switching to railway substations made it important that the power director have immediate and correct information in regard to his substations at all times.

One of the first supervisory systems was installed between the Sherman Creek Station of the United Electric Light & Power Co. at 201st Street and Broadway, New York City, and the load dispatcher's office of the New York Edison Co. at 38th Street and First Avenue, New York City in 1915. It used a form of step-by-step selector relay developed about that time for automatic telephone application. It gave indication at the dispatcher's office of the open and closed position of about one hundred oil circuit breakers using a total of six wires between the generating station and the load dispatcher's office.

The next step was made when the Receiver of the Des Moines City Railway expressed a desire for some means of isolating his automatic railway substations in case of an emergency such as a fire or an accident. This demand was met by the development of the selector supervisory system and followed promptly by the development of the distributor supervisory system. Next in order came the code visual, the audible, the synchronous relay and lastly the carrier current supervisory system. Beside these, developed and standardized by the manufacturing companies in this country, there has been a number of systems developed by the employees of many corporations not only in the railway field but also in the central station and industrial fields. These, however, have usually been limited to a definite field of application and have not been extended to become a commercial article of trade.

SELECTOR

The selector system was the first one developed for commercial application which is still on the market. It uses the essential elements of the telephone train dispatching call system modified for the control and indication of remote electric power apparatus. An installation made in 1920 is still in active service.

A key, a selector, some indicating lamps, and three line wires form the essential elements. The key when turned and then released makes and breaks an electric circuit through two of the wires to which all of the selectors in the outlying stations are connected in multiple. The key in operating sends out a predetermined number of electric impulses spaced in a definite time sequence thus forming a code. The selectors are provided with contacts mounted so as to make an electric circuit when a ratcheted wheel moves a given number of steps. The code sent out by the key starts all of the selectors simultaneously.

1. Engineering Dept., General Electric Co., Schenectady, N. Y.

To be presented at the Midwinter Convention of the A. I. E. E., New York, N. Y., February 8-11, 1926.

Only that selector, however, which is arranged to respond to the code sent out by the key closes its contacts. The other selectors drop out successively as the code being sent fails to give their combination. Thus, there is usually one hand-operated key at the controlling station for each selector contact at the outlying station. For the return indication

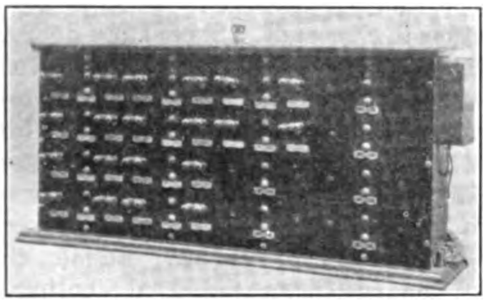

FIG. 1—LAMP AND KEY CASE FOR DISPATCHER'S OFFICE OF SELECTOR SUPERVISORY SYSTEM

there is provided at the outlying station a motor operated key for each group of four or less pairs of functions at that station to be indicated. Upon the operation of any supervised device in an outlying station, auxiliary contacts upon it start the motor key. This then sends back to the controlling station a code

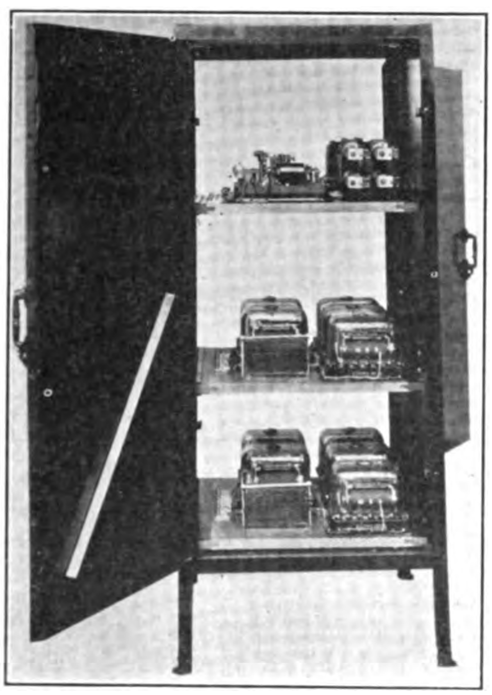

FIG. 2—SENDING APPARATUS IN CABINET OF SELECTOR SUPERVISORY SYSTEM

similar to that sent out from the controlling station to perform an operation. The selector located at the controlling station which is set to close its contacts upon the receipt of the code operates indicating lamps to show the position of the device supervised.

All of the outlying stations of a selector supervisory system are connected to one controlling station by three line wires. At each outlying station, the equipment is multipled to two of the wires as they pass by while the third wire loops into each station. The two wires as before mentioned are used for sending out the code for causing an operation to be performed and for transmitting back the code which results in giving an indication by lamps of the position of the equipment supervised. The third wire is used to lock out all the stations connected to the system excepting the one being controlled or the one sending in a code for causing an indication to be shown.

An arbitrary maximum of fifteen outlying stations may be connected by the usual selector systems to the controlling station. Each outlying station may have a maximum of eight devices to be supervised if there are as many as fifteen stations, or if there are fewer, each

FIG. 3—LAMP AND KEY UNIT FOR DISTRIBUTOR SUPERVISORY SYSTEM

outlying station may have a maximum of twelve or fifteen. The maximum number of devices, however, which can be most economically supervised by a single selector system depends largely on circumstances but under present conditions should never exceed fifty or sixty.

The selector system requires about nine seconds to send out each code, and complete an operation. Therefore, if ten outlying devices were to be operated it would take about one and two-thirds minutes to send out the code and operate these devices.

DISTRIBUTOR

The distributor system was the next type of supervisory system to be developed. It is an adaptation of the automatic printing telegraph in commercial use today on practically all the principal telegraph circuits. An installation of this type of supervisory system made in 1921 is still in active service.

A key, a distributor, a polarized relay, some indicating lamps, and four line wires form the elements. The key is usually a two-position one and is the equivalent of a double-throw switch. When turned to either

position it makes a circuit between a common wire and either the positive or negative side of a source of power and a segment on the distributor. The distributor consists essentially of three sets of coaxial segments insulated from each other. Each segment of one set is connected individually to its control key. Each segment of the second set is connected to the coil of a two-position polarized relay which is

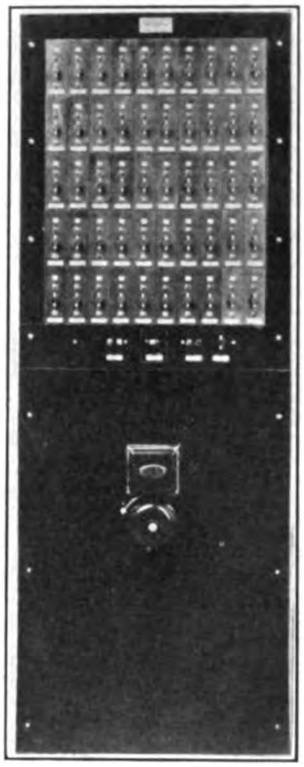

FIG. 4—PANEL CONTAINING LAMP AND KEY UNITS

For the control and indication of fifty circuit breaker equivalents in distributor supervisory system

associated with the appropriate indicating lamps. A set of segments midway between these two is used for synchronizing the distributor in the outlying station with the distributor in the dispatcher's office, synchronism being checked each five segments or ten times per revolution.

The distributors are each provided with three sets of brushes which rotate over the coaxial segments and make connections successively between each individual segment and a continuous segment in each set thus permitting a momentary electric circuit to be made through the distributor. The brush arms of each distributor are driven through a reduction gearing by a direct-current motor from a trickle-charged storage battery and are provided with a centrifugal governor for maintaining constant speed within quite narrow limits. The brush arm has a speed of about twelve rev. per. min.

At the controlling station are located the control key, indicating lamps, one distributor for each group of fifty or less devices to be supervised, and one relay for each device to be supervised, as well as suitable battery or other power equipment. At the outlying station are located a similar distributor for each group of fifty or less devices to be supervised in that station, one relay for each device to be supervised and the necessary battery or other power equipment.

The system operates continuously. This means that the positions of all devices which are supervised are automatically checked twelve times per minute or once each five seconds. Should any device change its position the change is indicated at the controlling station within five seconds of the time the operation has occurred. If several devices or the entire group connected to the system change position simultaneously, the lamps at the controlling station will give correct indication of the new position within five seconds of the time the change has occurred. Besides, the workability of the system is indicated continuously in much the same manner as the pulse indicates the general health of a human being.

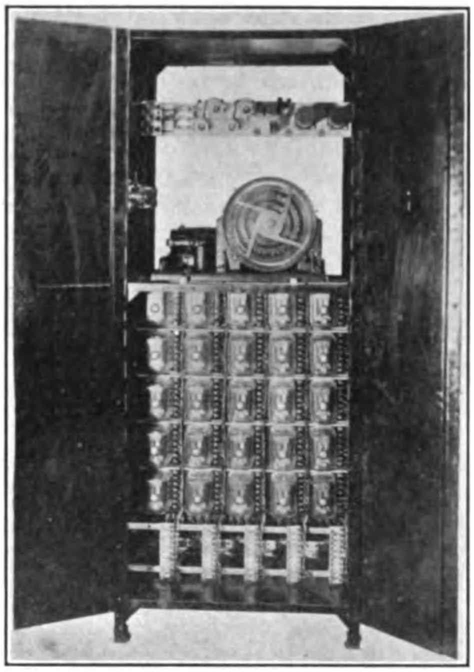

FIG. 5—RELAY AND DISTRIBUTOR CABINET

For control and indication of fifty circuit breaker equivalents in the distributor supervisory system

To open or close an oil circuit breaker or perform any similar function it is merely necessary to turn first one key and then a master key. This changes the polarity of a segment on the distributor at the controlling station and within five seconds momentarily energizes a corresponding segment on the distributor at the outlying station. This causes the position of the polarized relay connected to that segment at the outlying station to change in accordance with the impulse sent out from the controlling station and the operation desired is performed. Immediately the operation is completed auxiliary switches on the device supervised

change the polarity on an associated segment on the distributor at the outlying station. This, within a maximum time of five seconds, changes the polarity of a corresponding segment on the distributor at the controlling station which in turn changes the position of associated polarized relays located there. The relays then change the lamp combinations to indicate the new positions of the devices supervised at the outlying station.

Audible

The audible system is an adaptation of the automatic telephone being applied in many large and small telephone systems today. Its essential elements are a dial, a telephone line, telephone lamps, selectors and a

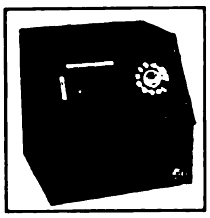

Fig. 6—Dispatcher's Sending Station for Westinghouse Audible Supervisory System

receiver or loud speaker. Operation is secured by dialing as in calling a number by an automatic telephone. The first dialing selects the station to be supervised, it being possible to connect as many as six to a single controlling station by a single pair of tele-

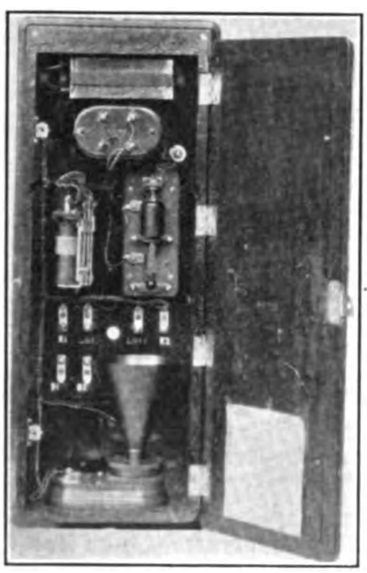

Fig. 7—Dispatcher's Sending Cabinet for G. E. Audible System

phone lines. The stations not selected are locked out by the operation of suitable devices in their equipment.

The station selected sets up a series of impulses indicated at the controlling station by a series of tones in code through a receiver or loud speaker located at that point.

The next dialing causes the desired operation to occur in the outlying station by setting up a suitable path in a relay combination finally closing the contacts of an operating relay. When the operation directed has been performed, auxiliary contacts on the device actuate other relays which in turn set up impulses indicated at the control station by a series of tones in code as before.

Code Visual

The code visual system is similar in principle to the selector system but differs quite markedly in its detailed design. It consists essentially of a key, with

Fig. 8—Lamp and Key Unit
For code visual supervisory system

its associated lamps, groups of relays at the controlling station and similar groups at the outlying station. It uses two common wires between the control station and all of the outlying stations and in addition one

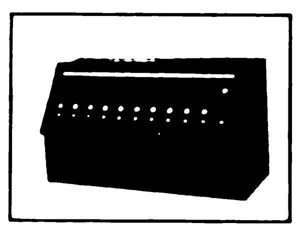

Fig. 9—Dispatcher's Lamp and Key Cabinet
For code visual supervisory system

individual wire from the controlling station to each outlying station. Thus, if there were three outlying stations, there would be five wires starting from the controlling station and running to the first outlying station, four running to the second outlying station and three to the third outlying station.

An operation is performed by moving a three-position key to either of the two extreme positions. This com-

pletes an electric circuit which causes groups of relays at the control station to send out a code of successive impulses. These impulses select suitably coded groups of relays at the outlying station. If the code is not received correctly at the outlying station, the controlling station then again starts the code out and continues to send it at intervals until correct code is received at the outlying station. If the code, however, is repeated correctly at the outlying station, then an

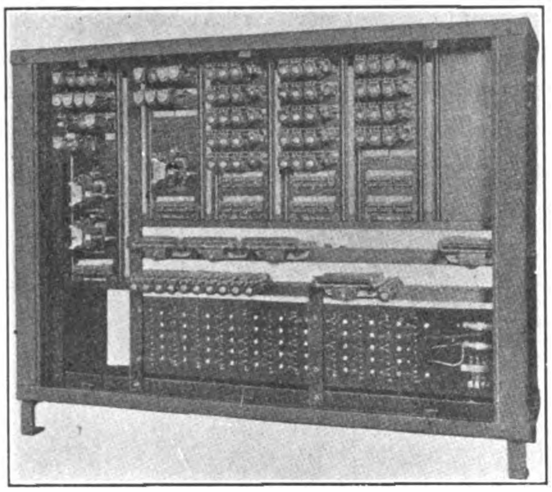

Fig. 10—Relay Equipment in Dispatcher's Office
For code visual supervisory system

impulse is sent out from the controlling station which causes the operation desired to be completed.

When the operation of a supervised device has occurred an auxiliary switch connected to it causes a code to start from the outlying station. This is formed and transmitted to the control station in the same fashion as is the operating sequence from the controlling station. When the correct code is checked the lamp signals at the controlling station are changed to indicate the new position of the supervised device.

This system operates devices successively and it requires about nine seconds per device to cause a series of operations. If, therefore, ten devices were to be operated it would take about ninety seconds to operate the devices.

Synchronous Relay Visual

The synchronous relay visual supervisory system is an all relay system which uses the principle of step-by-step synchronous selection. It consists essentially of a two position key with its associated lamps, a start key and relays in the controlling station, four wires between the controlling station and the outlying station, and relays in the outlying station.

When an operation is to be performed, the two-position key is turned from the position it occupies to the other position and the start key is pushed. This immediately causes a simultaneous operation of relays in the control station and the outlying station until the point is reached in the sequence in the outlying station corresponding to the position of the key in the controlling station. Operating current then passes through the signaling circuit from the control station to the outlying station and causes the desired operation to be performed. When the device supervised has had its position changed, auxiliary contacts on it transmit a return signal in a similar fashion to the controlling station causing the lamps located there to change in accordance with the changed position of the apparatus in the outlying station.

Two of the four wires between the control station and the outlying station are used for keeping the signaling relays at the two stations in step as they are moved from point to point in a definite sequence. The other two wires are switched by the operation of these relays from one device to another as occasion demands to cause operation or indication of that device.

Carrier Current

Carrier current has been developed for use with the selector and code visual systems. Both systems use codes of impulses for causing an operation to be performed and for causing an indication of that operation to be registered. The carrier current equipment consists of the necessary tubes, reactors, condensers

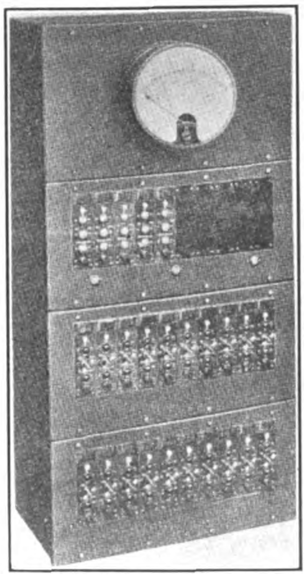

Fig. 11—Cabinet Containing Lamp and Key Units and Ammeter
For the control and indication of three circuit breaker-equivalents by the synchronous relay supervisory system

and resistors for generating high frequency at the controlling and outlying stations.

In general, the code is transformed from pulsating alternate polarity impulses to high frequency impulses and is transmitted over one line and ground or a pair of lines which may at the same time be used for communication or power transmission purposes. The carrier current equipment is connected to the transmission circuit by a condenser or other suitable coupling.

Carrier current for use with supervisory systems takes the place of the special line wires required where direct-current impulses are employed. It permits the use of practically the same equipment, so far as the controlling station and outlying stations are concerned as is used for direct-current. The only difference is that where direct-current is employed, special line wires are required, while where carrier current is employed, any existing wires can usually be used.

Wireless

Wireless has been considered for use with supervisory systems but to date no commercial development or application is known by the writer. The art seems not yet to have developed sufficiently.

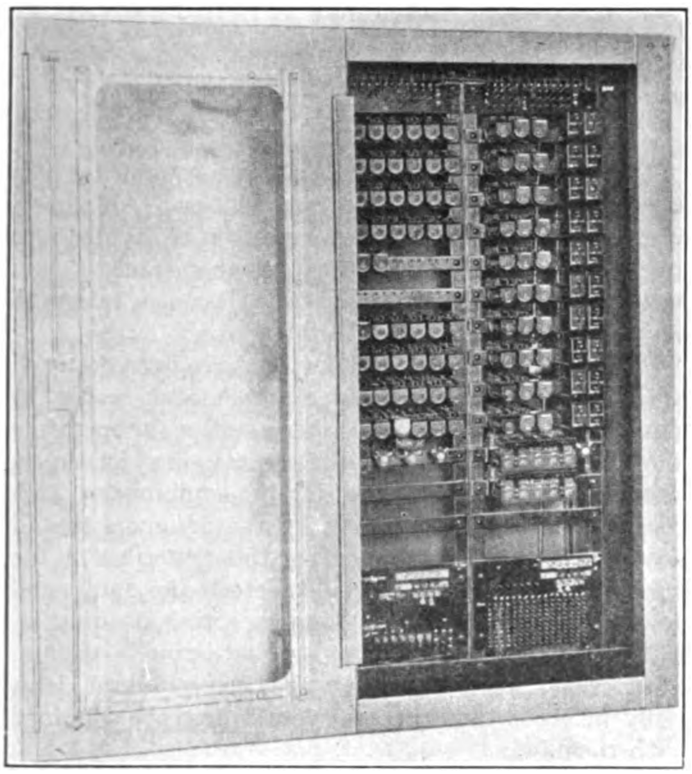

Fig. 12—Relay Cabinet for Dispatcher's Office—Synchronous Relay Supervisory System

Control Station

The control station equipments provided for the various types of supervisory systems which have been described vary one from another.

The selector system uses two keys, one to perform a closing or similar operation, the other to perform an opening or opposite operation. The key is quite similar to that used in the call stations of the Western Union Telegraph Company. The key is turned but nothing happens in the external circuit until it is released. The turning of it winds up a helical spring. As soon as the key is released the helical spring rotates it in the reverse direction under the control of a fly ball governor in order to obtain practically constant speed. In rotating back to its original position it opens and closes contacts in a definite sequence. If these contacts are suitably connected in an electric circuit they thereupon form a code of successive impulses.

As before stated two keys are required for each pair of functions. Associated with these two keys are two telephone lamps, capped with suitable lenses. These indicate the open or closed position of the device supervised. In place of indicating the position of a device if it is desired to indicate the position of water level or the position of a gate then the lamps only are used and as many of them are employed as positions to be indicated are desired.

The distributor system uses a combination of three telephone lamps and one two-position key to obtain control and indication. The two position key performs the same connections as a single pole double throw switch having no mid position. Associated with it are three telephone lamps. One is capped with a red lens, one with a green lens and one with a white lens. The red and green capped lamps indicate the closed and open position of the device supervised or any other indication usually desired. The white capped lamp is lit only during the time that a function has been called for and is put out immediately after that function has been completed and a return indication showing the completion of this function recorded at the controlling station. It is also lit should a device supervised at the outlying station automatically change its position, in which case it remains lit until the key in the controlling station is turned to acknowledge the operation at the outlying station. For each group of fifty two-position keys with their associated lamps there is one master key. The master key is turned after the two-position keys have been placed in the positions corresponding to the one which it is desired that the outlying supervised devices take.

The audible supervisory system employs a dial similar to that used for automatic telephones. In one commercial scheme, this dial is identical with that used for automatic telephones; in another commercial scheme this dial is similar but has had its speed altered to make it correspond to that of the selectors used. No lamps are used with the audible system, the operator depending upon hearing certain code tones in a receiver or loud speaker for indications.

The code visual supervisory system uses a three-position key associated with three telephone lamps capped by red, green and white lenses in much the same fashion as does the two-position key with its associated lamps in the distributor system.

The synchronous visual supervisory system employs a dispatcher's equipment consisting of a two-position key, a locking-type push button and three-telephone lamps capped by red, green and white lenses. The two-position key is to fix the operation while the push button is to stop the synchronous relay control equipment at any point.

Various methods have been employed for mounting the controlling lamps and keys. They may be placed on vertical panel boards, set into desk tops or even placed in a system diagram. The mounting best suited for any particular application depends to a large measure upon the individual requirements.

Application

The application of supervisory systems to any existing or new electric power transmission or distribution systems requires careful study in order that a maximum benefit may be derived. It is necessary to know intimately the method of operating the network of lines, feeders, and machines as well as the electric power traffic requirements. For congested districts where an emergency may at times require the rapid re-establishment of service, the speed of operation of a supervisory system is quite essential. On interurban railway projects, however, where automatic substations are located at intervals along a narrow strip of territory and where there are only three or four devices or functions to be supervised in each station, speed is not as important as line maintenance so another type of supervisory system is usually chosen. In some cases, the revenue derived from a station warrants only the most inexpensive supervisory system. Hence, here would be a place for the so-called audible type where the operator checks manually and at intervals determines by sound the condition of the equipment in the outlying station. Again, on a high-tension transmission system where distances often exceed one hundred miles the carrier current supervisory system is the best choice.

In applying supervisory systems it must be clearly borne in mind at all times that they are quite different in their performance as contrasted with the usual types of remote control systems. Each has its limitations. Remote control systems are in general limited to distances of several miles while the supervisory systems may be used for distances up to several hundred miles. Supervisory systems require an appreciable time interval averaging about five seconds for the completion of an operation through their medium while remote control systems operate practically instantaneously. So in applying supervisory systems, care must be exercised to take into account all of the electric power system characteristics as well as the limitations of the supervisory system.

Installation

The correct installation of a supervisory system is quite as important as its selection if the best results are to be obtained. Supervisory systems use currents of telephonic magnitude while remote control systems use currents of power magnitude. Hence, insulation and current leakage require very careful attention for the successful installation of a supervisory system, telephone practise being the standard toward which the installation of these systems must tend. The steam railroads have recognized these requirements when installing the selector type telephone train dispatching call system. More and more of them are going to the higher grade lead-covered paper-insulation telephone cable for their train dispatching circuits. The same cable and the same type of insulation are generally recommended as best practice for supervisory system installations.

Checking

Supervisory systems from a checking standpoint may be classified into two groups. One group requires checking at intervals, the other group is automatically checked at intervals.

All systems excepting the distributor system require manual checking at intervals. The distributor system has a distinct advantage in that it automatically checks the position of all of the devices connected to it at frequent intervals besides indicating its readiness to serve continuously.

Maintenance

The maintenance of a supervisory system depends upon its initial design and installation. All supervisory systems may for this comparison be divided into two classes. One class uses telephone relays and auxiliaries throughout. The other class uses telegraph relays and similar devices throughout.

The telephone relays and devices have been designed with the fundamental idea that someone would be present not only at the subscriber's station for operating the equipment but also at the central office for supervising and constantly inspecting the equipment. This results in a tacit assumption by the designers that if anything should go wrong either the subscriber or the wire chief or operator would detect the fault and correct it, no harm being done excepting possibly an interruption of service from one subscriber's station. Such relays particularly require inspection at least daily in order that the best results may be obtained with them.

The systems using telegraph devices may be typified by the selector system. Here the devices are large and substantial and so designed as not to require attention for years at a time. To be sure, there is quite a difference in the cost of the individual devices since the telegraph devices are made in very much less quantity than are the telephone devices. Contrasted, however, one with the other is the fact that the telephone type of devices require more maintenance and adjustment than do the telegraph devices.

Protection

Supervisory systems operating over special wires require protection particularly where these wires are subjected to lightning, inductive and similar high voltage disturbances. In general, isolating transformers or drainage coils cannot be used because these transformers would interrupt the flow of signals and the drainage coils would drain off the signal current. So

far as is known the best type of protection is for the conductors to be placed in cables. For this purpose paper-insulated lead-covered cable having an insulation which will withstand 1000 volts between conductors and 3500 volts between conductors and lead sheath is usually recommended.

The question of protection is an active one at the present time and many of the operating companies as well as the manufacturers would be interested to hear what other operators are doing to maintain their supervisory systems with a maximum of protection and a minimum of interruption.

TELEMETERING

A discussion of supervisory systems would not be complete without brief mention being made of telemetering. Telemetering furnishes the concluding link in the development of the art of supervising remotely located power apparatus.

Telemeters have been developed for transmitting the readings of ammeters, voltmeters, watthour meters, wattmeters and power factor meters over telephone lines the same distance as supervisory systems can be operated. They use practically the same type of relays at the originating and receiving ends of the telephone lines and in certain designs it has been found possible to combine the telemetering and supervisory functions on the same wires. In one particular installation recently made, two incoming lines, two synchronous converters and nine feeders were controlled and indicated and the readings of two watthour meters transmitted back to the controlling station, all over two pair of telephone lines between the controlling station and the outlying station. This is not a limiting number of things which could be done over these four wires but represents only about one-third of the functions and readings which could have been obtained if desired.

FUTURE

Supervisory and telemetering systems are just about being recognized by the engineering public. They are relatively new although a number of installations are now in operation. Nevertheless, it is believed that only an initial advantage has been taken of them and that they are not yet as thoroughly a part of electric power transmission and distribution engineering as are transformers, turbines, and the more commonly accepted pieces of electrical apparatus.

It is my firm belief that supervisory and telemetering systems in combination with automatic stations represent as distinct an advance in the electric art as has the development of the automobile in the transportation problem. It is also believed that a very great change will be effected in electrical engineering practise during the next ten years as a result of the economic application of supervisory and telemetering systems.

FLUX IN A CIRCULAR CIRCUIT

By CARL HERING

Fellow, A. I. E. E.

The flux density, H, at the center of a circular circuit of one turn is known accurately to be $2\,\pi\,i/r$; in fact, it has been made the quantitative connecting link between current and magnetism and the basis of the ampere. But the H in any other part of the circle is very difficult to calculate as it involves elliptical integrals, and to integrate these for getting the total flux is almost hopelessly complicated and then at best only approximate.

The density at any point outside of a single, straight, conductor (one far removed from its return) is definitely known to be $H = 2\,i/r$, and the total flux around any length l and radius a, up to any radial distance r, is also known definitely to be $F = 2\,l\,i \log_e\,(r/a)$. This, however, does not include the flux inside of the wire.

By calculating the total flux in a circular circuit indirectly from Kirchhoff's well-known, though only approximate, formula for self-inductance, $L = 2\,l\,(\log_e\,(l/a) - 1.508)$ in which a is the radius of the wire, and l the length, the author found, over extremely wide ranges of the radius r (a being constant),

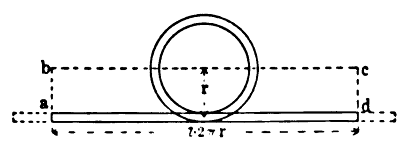

FIG. 1

the interesting result that the total flux in a circle of radius, r, seems to be equal to that around a length, l, of single, straight, conductor of equal length (that is, equal to the circumference of the circle) and up to a distance r from the axis, that is, to that in the rectangle $a\,b\,c\,d$.

There is a small, though constant, difference (always greater for the circle) due undoubtedly to the flux inside of the wire, which is included in the formula for the circle but not in that for the single conductor; these lines have only a fractional effect in the induction. The agreement is of the kind that strongly indicates that this equality would probably be found to be theoretically exact for the same size of wire if the theoretically definite value of the flux in a circle could be found; when a result is indicated or known, a proof is sometimes more easily found. Such being the case, the total flux in a circle could be expressed by a simple, theoretically exact, definite formula, independent of the self-inductance, and the latter checked by it, so far as quantity of flux is concerned.

Had our forefathers, in formulating our units, adopted as their fundamental the single conductor instead of the circle, the factor π would have dropped from some of the present fundamental relations.

The Ratings of Electrical Machines As Affected by Altitude

BY CARL J. FECHHEIMER[1]

Fellow, A. I. E. E.

Synopsis.—*The paper contains equations applicable to machines cooled by forced air convection currents. It is to be hoped that the A. I. E. E. Standards Committee will find some helpful suggestions in the paper.*

Ignoring differences in ambient temperature, the effect of altitude may be considered from two standpoints:

(a) The change in temperature rise, the rating remaining the same; or (b) the change in rating, the temperature rise at a given altitude equaling that at sea-level. The applications of both are considered, and equations are solved in both ways. The difference in ambient temperature at sea-level and at altitude is also taken into consideration in other equations.

The present A. I. E. E. rule is known to be faulty, applies only on the basis of temperature change, and starts at 1000 meters. These and other objections are believed to be met in this paper.

Several of the equations are plotted in families of curves, which should be of assistance to the reader. By assuming other values for some of the factors, other similar curves can be drawn.

In Appendix I, the derivations of equations are given. Appendixes II and III cover discussions of two of the factors used in the equations. In Appendix IV, some cases other than a slotted core are discussed.

A number of assumptions were made in the derivations of the equations: (1) The temperature coefficient of resistance was neglected. (2) The heat that flows transversely through the insulating wall is the same percentage of the heat generated in the copper at altitude as at sea-level. The equations are intended to apply to a slotted core, although they may be used for other parts of an electrical machine. Some examples are given in Appendix IV.

* * * * *

It has long been known that the density of a gaseous cooling medium influences the rate at which heat is dissipated from a heated surface, and at the February 1913 Convention of the American Institute of Electrical Engineers an attempt was made to correlate the temperature rise of an electrical machine with the barometric pressure. The revised A. I. E. E. standardization rules of December 1914 contained a statement for correcting temperature rise or rating to correspond to higher altitude, but the rule was intended only to be temporary, and it is now recognized as faulty. Several articles on this subject have recently appeared in the *Technical Press*[2] and in this article another method of attack is presented. It is to be hoped that the A. I. E. E. Standards Committee will find some helpful suggestions herein.

If the change in ambient temperature is ignored, it is evident that the effect of altitude may be considered from two standpoints: (a) The change in temperature rise, the rating remaining the same; or (b), the change in rating, the temperature rise at a given altitude equaling that at sea-level. Perhaps the most usual case, in which the purchaser of apparatus is interested, is how much less the temperature rise of the machine should be at sea-level than at a given altitude for the same load. The machine usually is tested near sea-level, and the customer wishes to know how much to decrease the test temperature rises to equal approximately those at the higher altitude. This is the most useful way for the correction to appear in the A. I. E. E. Standards. It is well, however, to include another method to cover the change in permissible output with altitude for operating recommendations. Equations in this form should also be of value to the designing engineer, as with their use he can tell how much the rating of a machine should be altered if transferred from sea-level to a higher altitude.

In the 1925 A. I. E. E. Standards, the rule reads: "For apparatus intended for service at altitudes greater than 1000 meters, it is provisionally agreed that the permissible temperature rises (to be included in contracts and checked by test at low altitude) shall be less than specified in these standards by one per cent of the specified rise for each 100 meters of altitude in excess of 1000 meters." The "Usual Service Conditions" are given as "(a) When and where the temperature of the cooling medium does not exceed 40 deg. cent. (b) Where the altitude does not exceed 1000 meters."

From the above it will be seen that in the existing A. I. E. E. rules:

(1) The correction for altitude is only on the basis of temperature change, not on a change in rating.

(2) The correction for altitude starts at 1000 meters, there being no correction for altitudes lower than that elevation.

(3) The correction for altitude is in very simple form, and as such cannot possibly bring in the various factors upon which such correction depends.

(4) The correction for altitude is empirical, and is based upon a limited amount of data; it is consequently liable to be considerably in error.

It is believed that these objections are met in this article. The derivation of the equations are given in Appendix I. The final equations may be put into various forms, according to what the point of interest is, what items are to be considered and what ones are to be ignored. They may be classified according to whether the solution is for temperature or for rating.

1. Research Engineer, Westinghouse Electric & Manufacturing Co., East Pittsburgh, Pa.

2. Particularly the paper by Doherty and Carter: "Effect of Altitude on Temperature Rise," TRANS. A. I. E. E., 1924, p. 824.

To be presented at the Midwinter Convention of the A. I. E. E., New York, N. Y., February 8-11, 1926.

The solutions are applicable to forced convection conditions only. The equations are intended to apply chiefly to a slotted core, in which some of the losses are constant, and some are proportional to the square of the load. The factor k is the fraction of loss in the core that is proportional to the square of the load at sea-level rating. (Thus, in estimating k, the numerator is the embedded copper loss, and the denominator the embedded copper loss plus the core loss). For the more usual applications of the equations 1 and 2 below, k fortunately does not appear. The equations can be applied to other parts than the slotted core, such as field coils in synchronous alternators, but then, although $k = 1$ and the equations are therefore simplified, account must be taken of the rate at which the field current changes with the load, and that is beyond the scope of this paper. In Appendixes II and IV, k and cases other than a slotted core are briefly discussed.

The final equations are as follows: (The list of symbols follows the equations.)

(a) Solutions for temperatures:

I. Surface temperatures only considered.

$$\frac{\theta_{s1}}{\theta_{s2}} = \left(\frac{B_2}{B_1}\right)^m \qquad (1)$$

II. Internal (copper) temperatures considered:

$$\frac{1}{b} = \frac{\theta_1}{\theta_2} = \frac{1}{a + (1-a)\left(\frac{B_1}{B_2}\right)^m} \qquad (2)$$

(b) Solution for Ratings.

I. Surface temperatures only considered.

1. Permissible temperature rise at a given altitude the same as at sea-level.

$$K = \sqrt{1 - \frac{1}{k}\left[1 - \left(\frac{B_2}{B_1}\right)^m\right]} \qquad (3)$$

2. Permissible temperature rise at a given altitude different from that at sea-level:

$$K = \sqrt{1 - \frac{1}{k}\left[1 - b\left(\frac{B_2}{B_1}\right)^m\right]} \qquad (4)$$

II. Surface drop and drop through insulation considered.

1. Permissible temperature rise at a given altitude the same as at sea-level.

$$K = \sqrt{\frac{1 - (1-k)(1-a)\left(\frac{B_1}{B_2}\right)^m}{a + k(1-a)\left(\frac{B_1}{B_2}\right)^m}} \qquad (5)$$

2. Permissible temperature rise at a given altitude different from that at sea-level:

$$K = \sqrt{\frac{b - (1-k)(1-a)\left(\frac{B_1}{B_2}\right)^m}{a + k(1-a)\left(\frac{B_1}{B_2}\right)^m}} \qquad (6)$$

In the above equations,

a = ratio of the thermal drop from the copper to the iron to the total temperature rise, at sea-level.

b = ratio of the total temperature rise at a given altitude to the total temperature rise, at sea-level.

B_1 = barometer reading at sea-level.

B_2 = barometer reading at a given altitude.

k = fraction of loss in the core that is proportional to the square of the load at sea-level rating.

K = fraction of sea-level rating that should apply at a given altitude.

m = exponent of barometric pressure ratio, and is the power to which that ratio should be raised to determine how much the surface temperature rise is altered by a change in density. Its value is between 0.75 and 1, and for most purposes 0.9 may be used.

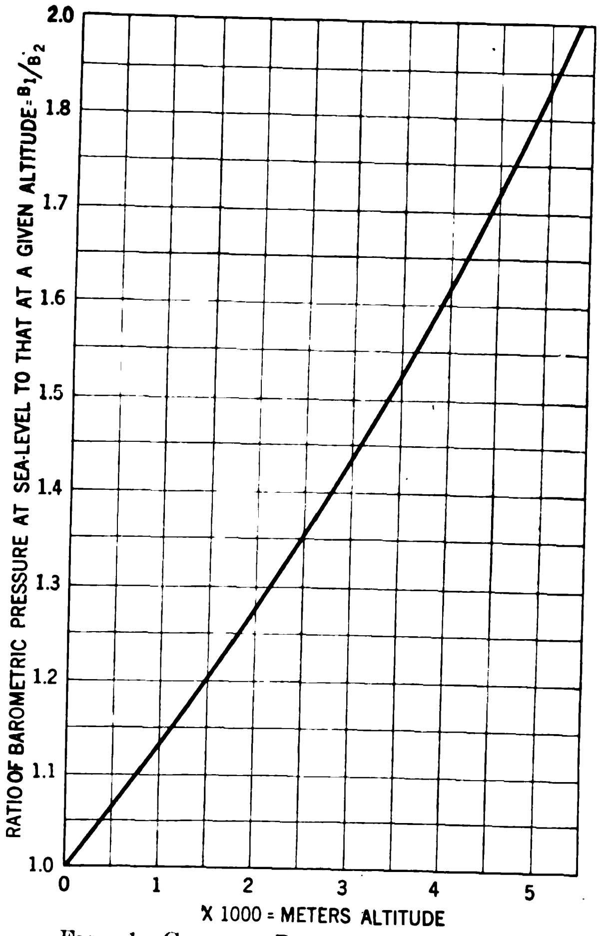

FIG. 1—CURVE OF BAROMETRIC PRESSURE

θ_1 = total temperature rise at sea-level.

θ_2 = total temperature rise at a given altitude.

θ_{s1} = temperature rise of the cooling surface above the ingoing air, at sea level.

θ_{s2} = same as θ_{s1}, but at a given altitude.

In Fig. 1 is plotted the ratio of the barometric pressure at sea-level to that at a given altitude. With these data, and that contained in equation (1), the curves in Fig. 2 have been plotted. They show what the ratio of the temperature rise at sea-level to that

at altitude should be, outside surface temperatures only being considered. They are plotted for three different

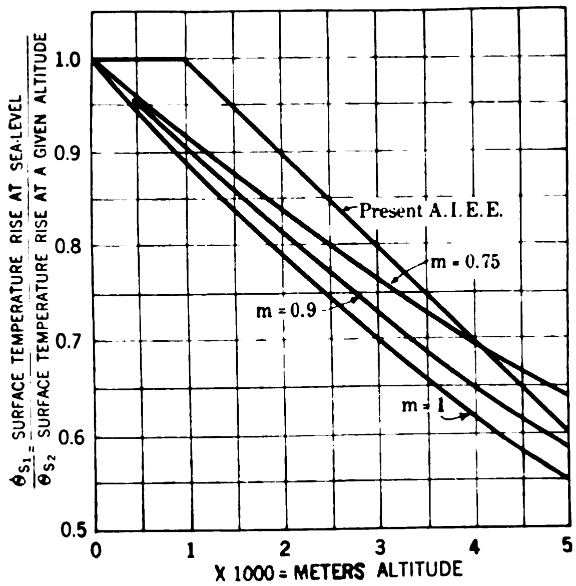

FIG. 2—RATIO OF SURFACE TEMPERATURE RISE AT SEA-LEVEL TO THAT AT A GIVEN ALTITUDE. "m" HAS A DIFFERENT VALUE FOR EACH CURVE

$$\frac{\theta_{s1}}{\theta_{s2}} = \left(\frac{B_2}{B_1}\right)^m$$

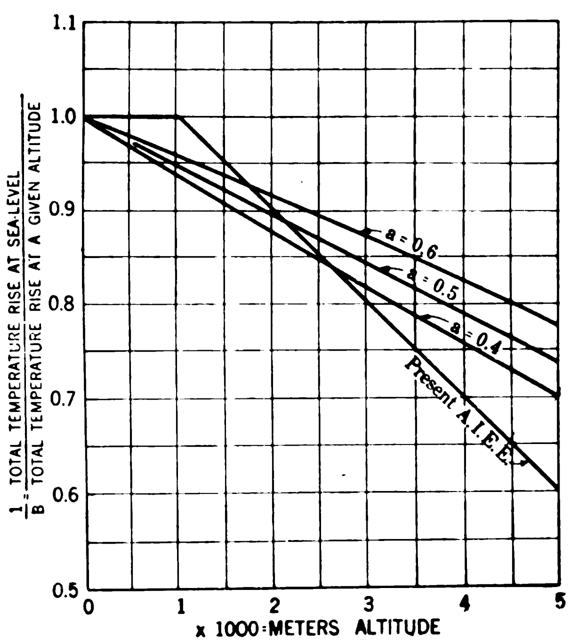

FIG. 3—RATIO OF INTERNAL TEMPERATURE RISE AT SEA-LEVEL TO THAT AT A GIVEN ALTITUDE. "a," THE RATIO OF DROP FROM COPPER TO IRON TO TOTAL TEMPERATURE RISE, HAS A DIFFERENT VALUE FOR EACH CURVE

$$\frac{1}{b} = \frac{\theta_1}{\theta_2} = \frac{1}{a + (1 - a)\left(\frac{B_1}{B_2}\right)^m}$$

m = 0.9 FOR ALL CURVES

values of m. The corresponding ratio, using the provisional A. I. E. E. rules, is also plotted. If the assumption is made that the probable most usual value of m is say 0.9, data from the curve corresponding to that value could conveniently be incorporated in the rules. Or, for m = 0.9, the data may be quite accurately represented by the equation

$$\frac{\theta_{s1}}{\theta_{s2}} = 1 - 0.09 \times \frac{\text{alt.}}{1000} \text{ up to about 4000 meters.}$$

In those machines in which temperatures are measured by embedded temperature detectors, equation (2) may be used. The plots for a = 0.4, 0.5, and 0.6 are given in Fig. 3 for m = 0.9. Those three

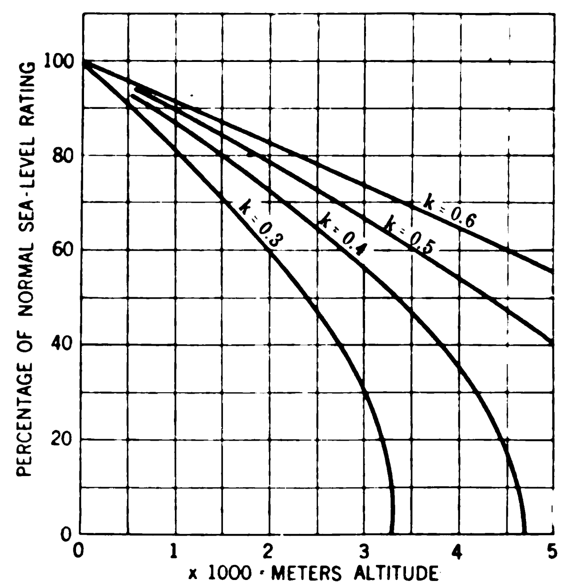

FIG. 4—RATINGS AS AFFECTED BY ALTITUDE. m = .9 FOR ALL CURVES, SURFACE TEMPERATURE ONLY CONSIDERED k, THE FRACTION OF LOSS IN THE CORE THAT IS PROPORTIONAL TO THE SQUARE OF THE LOAD AT SEA-LEVEL, HAS A DIFFERENT VALUE FOR EACH CURVE

$$K = \sqrt{1 - \frac{1}{K}\left[1 - \left(\frac{B_2}{B_1}\right)^m\right]}$$

curves are so nearly straight lines, that their approximate equations may be written as follows:

$$a = 0.4, \frac{1}{b} = 1 - 0.0604\left(\frac{\text{Alt.}}{1000}\right)$$

$$a = 0.5, \frac{1}{b} = 1 - 0.0526\left(\frac{\text{Alt.}}{1000}\right)$$

$$a = 0.6, \frac{1}{b} = 1 - 0.044\left(\frac{\text{Alt.}}{1000}\right)$$

Alt. = Altitude in meters.

The error for the high altitudes is not negligible, when the present A. I. E. E. rule is used. Thus, for a = 0.5, the temperature rise at sea-level is 0.6, instead of 0.785, of the rise at 5000 meters.

It will be noted that equations (1) and (2) do not contain k, the fraction of the loss in the core that is proportional to the square of the load. This follows

because the temperature of the external surface of, say an armature, is independent of the distribution of losses in the copper and iron. This is fortunate, as one less variable means simplification.

When the equations are solved for the rating ratio K, the term k is present. When so solved, the simplest solution, equation (3), applies when surface temperatures only are considered, and when the permissible temperature rise at a given altitude is the same at

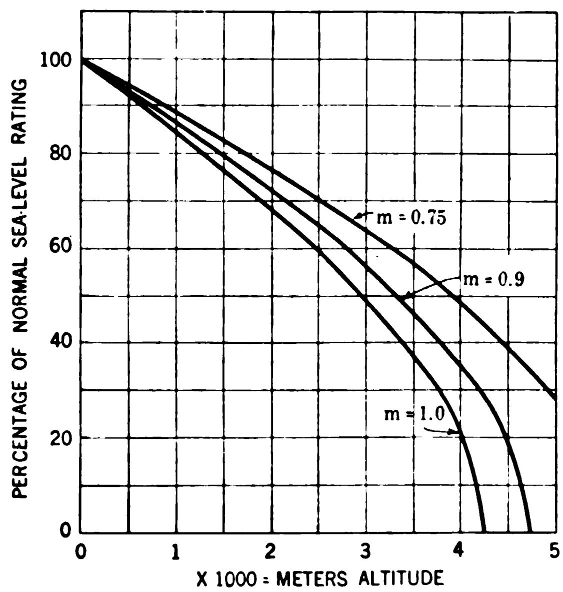

FIG. 5—RATINGS AS AFFECTED BY ALTITUDES. SURFACE TEMPERATURE ONLY CONSIDERED. "m" HAS A DIFFERENT VALUE FOR EACH CURVE. $k = .4$ FOR ALL CURVES.

$$K = \sqrt{1 - \frac{1}{K}\left[1 - \left(\frac{B_2}{B_1}\right)^m\right]}$$

sea-level. Perhaps that is the form of "rating" equation that an engineer would use most frequently. The percentage of normal sea-level rating may then be read directly from a family of curves, such as are shown in Fig. 4. Those curves were calculated on the basis that the barometric pressure ratio = 0.9, and that the value of k, the fraction of total loss that, at sea-level, is proportional to the square of the load, is constant along any one curve. The value to assign to k is considered in Appendix II. If a fixed value is chosen for k, the equation may again be plotted in the form of a family of curves, the exponent m being fixed for each curve. The value of 0.4 has been chosen for k in the plot in Fig. 5. From data on various machines, it seems as though 0.4 is a fair average value. As stated elsewhere in this paper, a value of 0.9 for m is probably the one that may generally be adopted. It is, therefore, suggested that for machines on which surface temperatures only are measured, the data from either Fig. 4 or 5, for $m = 0.9$ or $k = 0.4$ be used.

If again, surface temperatures only are considered, and values be assured for m and k, a family of curves may be plotted with the use of equation (4). As shown in Fig. 6, $m = 0.9$ and $k = 0.4$. Equations (3) and (4) are the same except that in (3) the temperature rise is taken to be the same at altitude as at sea-level, for a given rating $\left(b = \frac{\theta_2}{\theta_1} = 1\right)$. The ratio b is constant along any curve in the family in Fig. 6. It will be seen that it is quite within the range of possibilities for a machine to be good for a higher rating at a higher altitude than at sea-level. For example, if the air temperature is 40 deg. at sea-level, and the rise is 40 deg., then at a certain location at 3000 meters altitude, where the air temperature is 20 deg., the permissible rise is $40 + 40 - 20 = 60$ deg. to secure the same total temperature. The rating may then be, from Fig. 6, 110.5 per cent of sea-level rating.

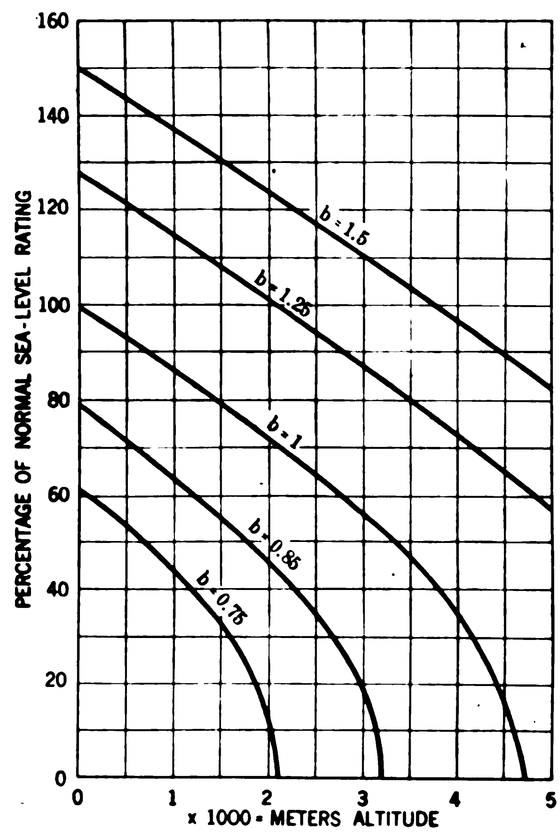

FIG. 6—RATINGS AS AFFECTED BY ALTITUDE. SURFACE TEMPERATURE ONLY CONSIDERED $m = 0.9$ AND $K = 0.4$ FOR ALL CURVES. B, THE RATIO OF THE TEMPERATURE RISE AT ALTITUDE TO THAT AT SEA-LEVEL, HAS A DIFFERENT VALUE FOR EACH CURVE.

Equations (5) and (6) are solved for the percentage of sea-level rating, account being taken of the drop through the insulation. Thus, the factor a is the ratio of the thermal drop from the copper to the iron to the total temperature rise, at sea-level. The assumption is made that the heat that flows transversely through the insulating wall is the same percentage of the heat generated in the copper at altitude as at sea-level. Evidently these two equations apply only when the temperatures are measured by embedded

temperature detectors. Equation (**5**) is the same as (**6**), except that in (**5**) the temperature rise at altitude is taken to be the same as at sea-level.

With the number of factors, as given in equations (**5**) and (**6**), it becomes more difficult to plot them in families of curves, and such curves are, therefore, not included in this paper. As those equations will probably be of value chiefly to the designer, and as it is necessary to evaluate such factors as k and a, with which frequently only the designer is familiar, he can readily substitute the numerical values in the equations and solve for K.

Appendix I

Derivation of Equations

For the usual case, the slotted core construction is of greatest interest. While that construction is the one chiefly considered, the equations are applicable to other parts. Some cases are considered in Appendix IV.

The derived equations take into account the relative values of $I^2 R$ loss, the percentage thermal drop through the insulating wall, and the comparative allowable temperature rises at altitudes and at sea-level. The equations are simplified if any of these are neglected. Furthermore, the equations can be readily applied if tests have been made at the factory where such items as the barometric pressure, ingoing air temperature, the temperature rise of the iron surface, and of the embedded copper have been measured, or whose approximate values may be assumed. The assumption is made that all heat is dissipated by forced convection currents of air, natural convention and radiation being of negligible influence. The equations, therefore, are not applicable to transformers, totally enclosed machinery, or other apparatus in which those two effects are predominant. The assumption is also made that in a slotted core the heat that flows transversely through the insulating wall is the same percentage of the heat generated in the copper at altitude as at sea-level.

Call L_1 the losses upon which the temperature in the member under consideration are dependent when operating at sea-level. (Usually embedded copper losses plus iron loss). Also k = fraction of loss L_1 that is proportional to square of the load, at sea-level. Then:

$$L_1 = k\,L_1 + (1 - k)\,L_1 \qquad (7)$$

Thus, $k\,L_1$ = variable losses that are proportional to the square of the load, and the remainder, $(1 - k)\,L_1$ = constant losses. At a given altitude, the constant losses are still $(1 - k)\,L_1$, and the variable losses are as at sea-level multiplied by the square of the ratio of ratings. If L_2 is the loss at altitude,

$$L_2 = k\,K^2\,L_1 + (1 - k)\,L_1 \qquad (8)$$

The difference between the surface temperature and that of the cooling medium adjacent to the surface is proportional to the losses, and inversely proportional to a fractional power of the density of the medium. The fractional exponent is probably between 0.75 and 1, and its value is further discussed in Appendix III. The cooling medium, air, is itself heated by the absorption of losses up to the particular surface, and that air temperature rise must be added to the thermal drop from the surface to the adjacent air. The air rise is inversely proportional to the density of the cooling medium. The temperature rise of the surface above the air entering the machine is then made up of two parts, one of which is inversely proportional to the first power of the density ratio and the other is inversely proportional to a power of that ratio whose value is between 0.75 and 1. In the general case, in which the temperature rise above the ingoing air is considered, the resultant exponent is probably not far from 0.9, but in these equations it is written as m. The equation coordinating losses and barometric pressures with surface temperature rise may then be written as:

$$\frac{\theta_{s2}}{\theta_{s1}} = \frac{L_2}{L_1}\left(\frac{B_1}{B_2}\right)^m \qquad (9)$$

Here θ_{s1} = temperature rise of cooling surface above the ingoing air, at sea-level. θ_{s2} = same as θ_{s1}, but at altitude. B_1 and B_2 are respectively the barometric pressure readings at sea-level and at altitude.

From equations (**7**), (**8**) and (**9**),

$$\frac{\theta_{s2}}{\theta_{s1}}\left(\frac{B_2}{B_1}\right)^m = \frac{L_2}{L_1} = k\,K^2 + (1 - k) \qquad (10)$$

Whence, for $\theta_{s2} = \theta_{s1}$,

$$K = \sqrt{1 - \frac{1}{k}\left[1 - \left(\frac{B_2}{B_1}\right)^m\right]} \qquad (11)$$

Equations (**11**) and (**3**), in the text are identical. Assuming that the load at sea-level and at altitude are the same, $K = 1$, and the equation may be written:

$$\frac{\theta_{s1}}{\theta_{s2}} = \left(\frac{B_2}{B_1}\right)^m \qquad (12)$$

This is the same as equation (**1**) in the text.

Consider next the transverse flow of heat through the insulation wall adjacent to the copper in the slot, the total temperature rise of the copper above the ingoing air θ_2 is the sum of the drop through the insulating wall θ_{i2} and the surface rise θ_{s2}. That is:

$$\theta_2 = \theta_{s2} + \theta_{i2} \qquad (13)$$

Similarly at sea-level, using subscripts 1 instead of 2,

$$\theta_1 = \theta_{s1} + \theta_{i1} \qquad (14)$$

The heat flows in part transversely through the insulation from the copper to the iron, and in part longitudinally and the relations are too complex to embody in these equations.[3] (In some cases the flow may be from the iron to the copper). It is believed, however, to be reasonable to assume that the percentage of the total heat generated in the copper that flows trans-

3. Those equations will be found in a paper by the author: "Longitudinal and Transverse Heat Flow in Slot Wound Armature Coils." Trans. A. I. E. E., 1921, p. 589.

versely is the same at a given altitude as at sea-level. The difference in temperature between the copper and the cooling surface may then be taken as proportional to the copper losses:

$$\frac{\theta_{i2}}{\theta_{i1}} = \frac{K^2\, k\, L_1}{k\, L_1} = K^2 \qquad (15)$$

Call a the ratio of the drop from the copper to the cooling surface to the total temperature rise at sea-level:

$$a = \frac{\theta_{i1}}{\theta_1} \qquad (16)$$

One other factor may enter, as the permissible temperature rise at a given altitude is frequently greater than at sea-level, due to the lower ambient temperature at the higher altitudes. The ratio of the permissible rise is:

$$b = \frac{\theta_2}{\theta_1} \qquad (17)$$

Equations (10), (13), (14), (15) and (16) may readily be combined, and the solution may be written as:

$$K = \sqrt{\frac{b - (1-k)\,(1-a)\left(\dfrac{B_1}{B_2}\right)^m}{a + k\,(1-a)\left(\dfrac{B_1}{B_2}\right)^m}} \qquad (18)$$

This is the same as equation (6) in the text. By taking the ambient temperature at sea-level to be the same as at altitude, $b = 1$, equation (5) is obtained. If in (18), a, the ratio of the drop from the copper to the iron to the total temperature rise at sea-level, be taken as zero, equation (4) is obtained. Then, again, if in equation (4), $b = 1$, equation (3) follows. Also, if in equation (18) the ratio of ratings at altitude and at sea-level be taken as unity, equation (2) is obtained. Equation (1) may be obtained from (2) by placing $a = 0$. Then the surface rises (θ_{s1} and θ_{s2}) are taken to be equal to the total rises θ_1 and θ_2.

Appendix II

Discussion of Values of k

The value of the fraction of the embedded loss that is proportional to the square of the load k is necessarily largely dependent upon the type of machine, upon the speed, upon the voltage, upon the choice of proportions by the designer, etc. A number of machines of three types were chosen at random, as given in the table.

SALIENT POLE ALTERNATORS

Rating at Sea Level

Kv-a.	Volts	Frequency	Rev. per min.	k
18750	12000	60	150	0.498
1250	13200	60	112	0.302
850	2200	60	100	0.730
12500	13200	60	720	0.370
10000	15000	50	600	0.590
				0.498 = Av. k

LARGE INDUCTION MOTORS

H. p.	Volts	Frequency	Syn. Rev. per min.	k
1200	2200	60	600	0.206
1200	6600	25	500	0.475
1400	2200	60	514	0.448
1500	6600	25	375	0.320
1200	2200	60	300	0.316
1500	2200	60	360	0.357
				0.353 = Av. k

D-C. GENERATORS AND MOTORS

Kw.	Volts	Rev. per min.	k
500	250	1200	0.216
1000	250	720	0.380
1500	250	514	0.420
300	250	150	0.407
600	250	100	0.450
1000	250	100	0.508
			0.397 = Av. k

Mean of the three values of k = .416

From Fig. 4 it will be seen that the value of k has considerable influence upon the rating. For the general average case, the value of 0.4 is probably not far wrong. The curves in Figs. 5 and 6 were plotted for that value. Inasmuch as the equations involving k are of principal value to the designer, he can readily determine the proper value to assign to it, and estimate the rating at the higher altitude by substituting in the proper equation. For short machines the longitudinal flow affects the distribution, and for such machines the value of k should be reduced.

Appendix III

Discussion of Values of m

The value to assign to m, the barometric pressure ratio exponent, could easily be made the subject of an entire paper. Only a brief outline of the subject and mention of several papers are given in this note. As stated in Appendix I, m is dependent upon two factors which are additive, (a) the rate at which heat is transferred from a heated surface to the moving fluid, and (b) the temperature increase of the cooling fluid from entrance to the machine up to the point under consideration. These two do not bear a fixed relation to each other; in one type of machine the relation may be quite different from another type. For example, in a d-c. armature, the temperature rise of the air up to the parts of the radial vents considered is probably quite small; on the other hand, in a high speed steam-turbine driven alternator the air rise is usually considerable before it reaches those parts of the vent ducts which are closest to the points where the temperatures are measured.

The volume of air per unit time which passes through a machine is independent of the barometric pressure. (This follows because the pressure generated by the fans, and the pressure drop through the various paths of the machine are both proportional to the density, and the generated and consumed pressures are equal to

each other). As the mass of air per unit of time is proportional to the density, the mass varies directly with the density or with the barometric pressure. As the temperature rise of the air is inversely as its mass, (assuming that the same heat is taken up by the air), the temperature rise is inversely as the barometric pressure.

In regard to the rate of transfer of heat from the surface to the cooling medium, there are a number of papers available. Perhaps the best work is that of Nusselt[4], and he found experimentally that the density ratio exponent is 0.786. Pohl[5] used that value in the derivation of equations applicable to machines using a closed circuit system of cooling. One of the most recent publications is that of Rice[6], who obtains his results largely theoretically, using the dimensional method, and in his final equations for heat transfer for the turbulent state of ideal gases, for smooth and for moderately rough surfaces, the exponent of density is given as unity. Rice's paper contains a large number of references, and any one interested can consult that paper. In the paper by Doherty and Carter[7], the exponent for forced convection was found to be 0.73, and to simplify calculations, they used 0.75. This value seems to be approximately correct for the machines for which they give data in their paper. As we understand their results, the exponent 0.75 takes account of the air rise as well as the surface transfer. It is felt, however, that their tests are too limited to warrant us to draw conclusions.

It is believed that, since the total drop is made up of two items which are additive, and since the exponent for one of them is probably not far from 0.80, and the other is unity, a mean of 0.9 may be chosen for the general case. It would be well to obtain further experimental checks. As may be seen from Figs. 2 and 5, if 0.9 be adopted, the error in temperature or in rating is not great for probable departures above or below this value.

Appendix IV

Cases Other Than A Slotted Core

The manner of treatment of a few cases other than a slotted core will be considered.

1. Commutators.

The losses are evidently the brush friction and $I^2 R$, the influence of windage loss upon temperature being negligible. The friction losses are evidently constant and the $I^2 R$ losses are proportional to the square of the load. Equations (**1**), (**3**) and (**4**) are applicable.

7. "Effect of Altitude on Temperature Rise." TRANS. A. I. E. E., 1924, p. 824.

2. Stationary Field Coils as in D. C. Machines.

A. Shunt Coils. If the field current may be assumed to be the same at all loads, and surface temperatures are to be measured, equations (**1**), (**3**) or (**4**) may be used; otherwise, if the temperature rise is measured by resistance, equations (**2**) (**5**) or (**6**) may be used, taking $k = 1$. If the field current changes with the load, the temperature equations (**1**) or (**2**) may still be used. Unless the change in current with load can be incorporated in a simple equation which can be combined with other elementary equations, the rating may be approximated by a cut-and-try method.

B. Series or interpole coils, or compensating windings. The current is proportional to the load, and the losses to the square of the load. If the surface temperatures only are to be measured, equations (**1**), (**3**) or (**4**) may be used, taking $k = 1$. If these windings are insulated and temperatures are measured by resistance, equations (**2**), (**5**) and (**6**) may be employed.

It is recognized that, due to change in armature losses with load, the temperature of the cooling air changes with the load. That introduces a complication, and furthermore, its influence is usually small, if consideration is given to the fact that at the higher altitude the rating and losses are reduced.

3. Revolving Field Alternator Field Coils.

A. Single layer edgewise winding. Temperatures measured by resistance. The temperature rise for a given load may be estimated by equation (**1**). The changed rating may be estimated by approximating the field current for various loads, and with the use of equation (**1**), calculate the temperature rise ratio. A curve may then be plotted coordinating temperatures with ratings.

B. Embedded windings, such as for turbo alternator rotors; or field coils for salient pole alternators with insulation. Temperature rise measured by resistance. Equation (**2**) may be used for temperature rise ratio. The changed rating may be estimated in the same manner as for single layer edgewise winding, except that equation (**2**) should be used instead of equation (**1**).

RAILWAY ELECTRIFICATION IN JAVA PLANNED

According to recent reports the electrification of the line Manggarai-Buitenzorg has been sanctioned by the Government. Plans for the project are now entirely completed, the execution of the work has already been commenced, and the necessary material will be ordered immediately. Barring unforeseen circumstances, it is expected, therefore, that the electrification of the entire line will be completed in two years. Furthermore, an amount of 100,000 guilders (the guilder now = $0.40) has been appropriated for preliminary work in connection with the electrification of the Poerwakarta-Bandoeng line, which will probably be the next to be electrified.

A New Wave-Shape Factor and Meter

BY L. A. DOGGETT, J. W. HEIM and M. W. WHITE*

Member, A. I. E. E. Non-Members

***Synopsis.**—A star-connected circuit consisting of two voltmeters and one variable condenser has certain properties upon which a wave-shape factor may be based. When the voltmeter resistances are equal to each other and equal to the condenser reactance, the ratio of the voltmeter readings will always be $(2 + \sqrt{3})$ for an alternator producing sine waves and always less than $(2 + \sqrt{3})$ for all other wave shapes. From any measured ratio of voltmeter readings, the purity of the voltage wave may be determined; furthermore, the maximum possible percentage of any single harmonic present in the wave can be immediately obtained (See Table III). For the experimental application of this method a wave shape meter is proposed for practical application which consists essentially of two voltmeters and a variable condenser. Such a meter has advantages over the method of analysis based on oscillograms, namely: (1) cost, (2) portability, (3) ease of experimental procedure and (4) rapidity of arriving at results. This method of attack is not intended to supplant the oscillograph but rather to supplement it. The method has been checked with the aid of a harmonic alternator and has been applied to the local power system and to various alternators available in the Electrical Engineering laboratories of the Pennsylvania State College.*

* * * * *

INTRODUCTION

FOR a long time the wave shape standard of the A. I. E. E. has been based on oscillograms. Recently† copies of seven oscillograms were sent to ten electrical manufacturing and power companies for measurement of deviation factor. The results obtained showed very considerable variations. For one oscillogram, the values found for this factor ran from 1 to 4.2 per cent, with an average value of 2.25 per cent. In other words, the maximum value was in excess of the average by 86½ per cent of the average value, while the spread between the maximum and minimum values was 3.2 or 142 per cent of the average value. For the other six curves the spread was less, but still considerable. The excess of the maximum values over the average values for each of the six other cases was 57 per cent, 54 per cent, 52 per cent, 47 per cent, 31 per cent, and 14 per cent. Quoting from the reference given, "The variations between results cannot be attributed to the processes of calculation employed, for neither the maximum nor the minimum spread occurred with the same party. The variations must, therefore, arise from difficulties inherent in the method such as, difficulty in evaluating exactly the ordinates of the oscillogram, errors in evaluating the area included by the squares of the ordinates in finding the effective value, errors in measuring the maximum differences between the ordinates of the oscillogram and the equivalent sine wave, especially when these differences occur in the steep part of the curve."

Another test was made to determine the accuracy attainable in the determination of the amplitudes of harmonics by analysis of oscillograms. Three waves were prepared by the synthesis of known harmonics and fundamental, the waves traced, and the results turned over to various parties to be analyzed. The results indicated that for harmonics below the 15th, average variations from the correct values of amplitudes of harmonics of ± 5 per cent might be expected.

The usual alternative to the use of the oscillograph is some sort of a circuit method of which many have been proposed but so far no one has been permanently adopted. Here still another circuit method is proposed, differing primarily from other circuit methods in that it is based on a three-phase circuit.

DESCRIPTION OF THE METHOD

Two voltmeters, V_2 and V_3 (Fig. 1) having equal resistances, and a variable condenser, C (whose range of reactance can be varied above and below the resistance of the voltmeters) are connected in star to the three-phase source whose wave shape is to be investigated. The value of C is adjusted until the ratio of the larger to the smaller voltmeter readings is maximum. That this ratio, R, is $(2 + \sqrt{3})$ for a pure sine wave is proved in the Appendix. The greater the deviation from a pure sine wave, the lower this ratio will become. It is the dependence of this ratio upon the harmonics present in the wave which makes it possible to use such a voltage ratio as a measure of the purity of the wave.

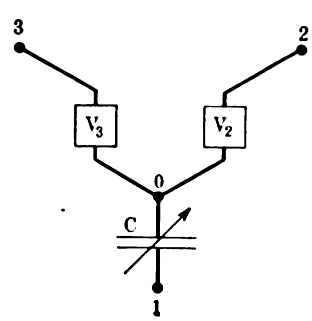

FIG. 1 A—A NEW WAVE-SHAPE FACTOR

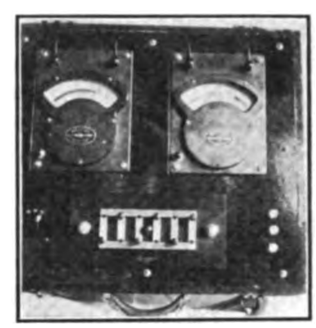

FIG. 1 B—WAVE-SHAPE FACTOR AND METER

The vector diagram of Fig. 2 gives an idea of the displacement of the neutral as the wave shape departs from a true sine wave.

By the use of the following formula, also proved in the

*All of Pennsylvania State College, State College, Pa.

†*Revue Generale de L'Electricite*, January 10, 1925, pp. 43-46.

To be presented at the Midwinter Convention of the A. I. E. E., New York, N. Y., February 8-11, 1926.

Appendix, the voltage ratio for any combination of harmonics may be calculated,

$$R = (2 + \sqrt{3}) \left[\frac{100 + a_2\,(\%\,H_2)^2 + a_3(\%\,H_3)^2 + \ .\ .\ .\ a_n(\%\,H_n)^2}{100 + b_2\,(\%\,H_2)^2 + b_3(\%\,H_3)^2 + \ .\ .\ .\ b_n(\%\,H_n)^2} \right]^{1/2} \qquad (1)$$

Where $\%\,H_2$ is the per cent second harmonic.
$\%\,H_3$ " " " " third "
$\%\,H_n$ " " " " n^{th} "

The a and b constants for the various harmonics are given in Table I.

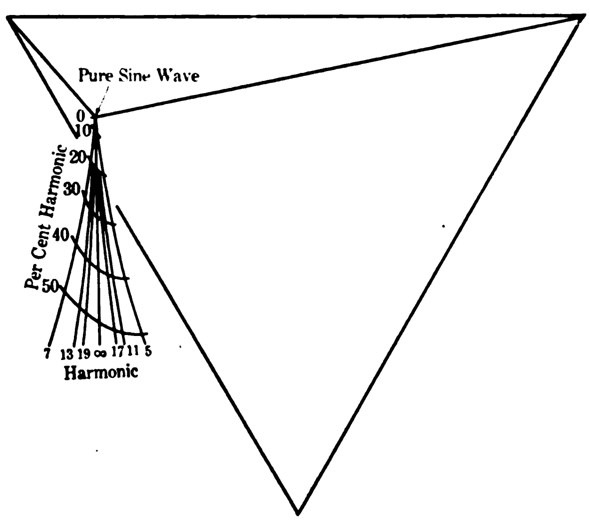

Fig. 2—Loci of Floating Neutral for Various Percentages of Harmonics. (Line Voltage Constant)

Since in the experimental application of this method, two voltmeters having equal resistances are required and as one meter must have a range approximately three times that of the other, some difficulty was experienced in selecting suitable meters from standard models, those of the dynamometer type being desired.

The meters first selected were a Weston instrument with a resistance of 301 ohms and a range of 30 volts, and a General Electric instrument having a resistance of 920 ohms and a range of 150 volts. Each voltmeter was equipped with a multiplier so as to arrange the resistance of V_2 in Fig. 1 equal to that of V_3. The voltmeters were then calibrated. Three one-μf mica and one eight-μf paper condenser were used. The capacities of these condensers were also checked.

The final arrangement, as shown in the photograph, Fig. 1, consists of two Weston dynamometer type voltmeters of 40- and 120-volts range respectively and of 1000.7- and 1000.0- ohms resistance respectively.

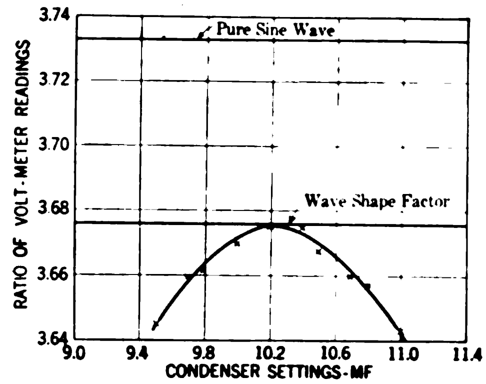

Fig. 3

Mounted in the same box are a one-μf. mica and two one-μf. paper condensers. The mica condenser is a Leeds and Northrup instrument, variable by steps of one twentieth μf. from 0 to one μf. The small switch in the lower left hand corner controls the paper condensers, giving zero, one, or two μf.

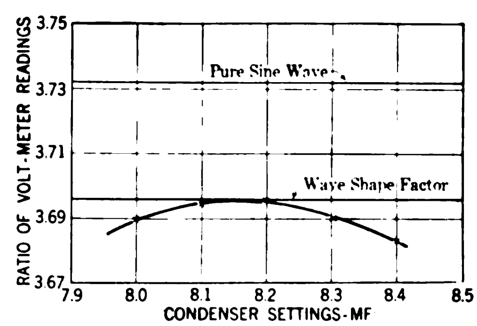

Fig. 4

Some Applications of the Method

With the apparatus as originally set up, tests were made on waves obtained from the Keystone Power Corporation System, from the Pennsylvania State College Power Plant (300 kv-a. turbo alternators), and various laboratory alternators. In the curves of Figs. 3 and 4 are plotted the data for two representative cases.

To obtain data for the curves of Fig. 5 the final arrangement shown in the photograph of Fig. 1 was used. If the following technique is employed, and if the frequency remains constant for about five minutes,

the results obtained are independent of voltage, capacity and magnitude of line frequency. The technique employed in obtaining the five dotted curves of Fig. 5 was to vary rapidly the capacity from 2.0 to

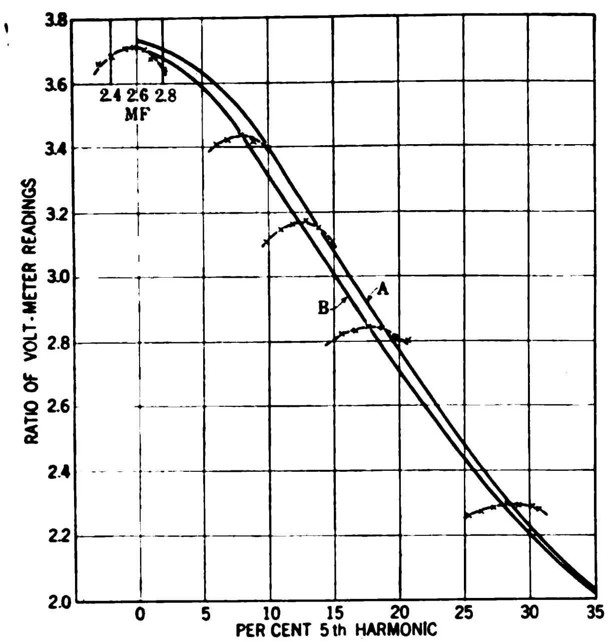

FIG. 5

three-phase supply was connected to the wave shape meter (Fig. 1). Ratio curves, such as shown in Fig. 5 were obtained for 0 per cent, 8.0 per cent, 12.8 per cent, 17.5 per cent, and 28.0 per cent fifth harmonics. Through the maximums of the five dotted curves is drawn a curve, *B*, which should check with curve *A*, the latter being calculated from formula (1). Discrepancies between curves *A* and *B* are chargeable to deviation from a pure sine wave on the part of the fundamental machine and to slight inequalities in the magnitudes of the three-phase voltages of the fifth harmonic machine. In searching for various factors to account for this discrepancy it was proved by test that the wave-shape factor is independent of the phase position of the harmonics.

CONCLUSIONS

1. *Value of Voltage Ratio to Be Met in Practise.* In addition to the values of wave shape factors given above for systems and dynamos tested in our laboratories, there is given in Table II, a compilation of wave-shape factors for some waves whose analyses into component harmonics have been found in the literature. It will be seen that wave-shape factors varying from 3.448 to 3.730 appear in practise. These factors were obtained by substituting the given percentage harmonics in formula (1).

TABLE II

Wave-Shape Factor	Per cent Harmonic									Reference

3.0 μf. by 0.1 μf. steps, reading the two voltmeters at each step. The maximum ordinate of the plot of the ratio of these observations is the wave-shape factor.

CHECK OF OBSERVATIONS AGAINST CALCULATIONS

In order to check this method the following test was carried out. The fundamental and fifth harmonic members of a three-phase harmonic alternator were used. A description of this machine is given in the Appendix. The phases of the fundamental machine were star connected, and each phase joined in series with the proper coil of the fifth-harmonic machine. This

Oscillograms were obtained from 19 machines of Table I of the 1919 report of the A. I. E. E. Subcommittee on Wave Shape Standards[13]. Based on analyses of these waves, the following wave shape factors were calculated:

3.717, 3.706, 3.717, 3.719, 3.698, 3.723, 3.715, 3.724, 2.746, 3.700, 3.700, 3.696, 3.698, 3.702, 3.700, 3.708, 3.702, 3.553, 3.349; *i. e.*, a range of 3.724 to 2.746.

2. *Interpretation of Voltage Ratios.* As previously stated a ratio of voltmeter readings of $(2 + \sqrt{3})$ or

13. Osborne

3.732 corresponds to a pure sine wave. Consequently the purity of a voltage wave may be immediately determined by noting whether or not the observed voltage ratio is equal to 3.732.

In case the ratio is found to be less than $(2 + \sqrt{3})$ it follows that the wave is not a pure sine wave. We may assume the absence of third harmonics or any multiple thereof in the ordinary commercial three-phase circuits. Furthermore, no second or fourth harmonics will be found in the waves from commercial alternators.

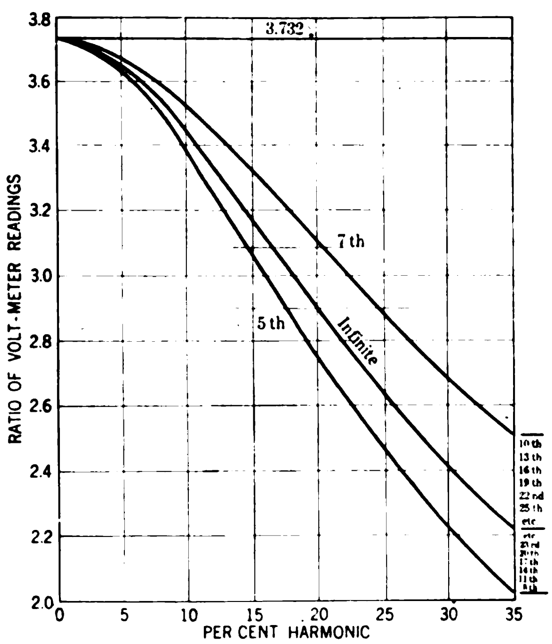

FIG. 6

The fifth and seventh harmonics are usually the most pronounced of all the harmonics, and Fig. 6 shows the ratio curves for these harmonics. If only a seventh harmonic is present, reference to Table III will immediately give the percentage harmonic corresponding to any observed voltage ratio.

TABLE III
7th Harmonic

Per cent Harmonic	Voltage Ratio
0	3.7320
1	3.7298
2	3.7232
3	3.7123
4	3.6974
5	3.6753
6	3.6530
7	3.6248
8	3.5999
9	3.5685
10	3.5298
11	3.4962
12	3.4572
13	3.4163
14	3.3742
15	3.3312

Reference to the curves of Fig. 6 shows that a given voltage ratio corresponds to a smaller percentage harmonic when this is a harmonic of an order other than the seventh. Consequently the *maximum* possible percentage of any single harmonic present may be immediately obtained from the observed voltage ratio by reference to Table III. For example, a voltage ratio of 3.33 corresponds to the presence of a 15 per cent seventh harmonic (From Table III) and inasmuch as this ratio corresponds to a smaller percentage of any single harmonic other than the seventh, it is quite conservative to state that in a circuit which gives an observed voltage ratio of 3.33, there is no single harmonic present which amounts to more than 15 per cent of the fundamental. In other words, this last deduction holds not only for the case where the seventh alone is present but also where there are other harmonics found in addition to the seventh.

In brief, it can be stated that this method is capable of giving at once from a single observation of voltage ratio, the maximum possible percentage of any harmonic present in a wave, when the experimental conditions have been properly adjusted as described above.

3. *Accuracy of Results.* The accuracy with which the data may be obtained is quite high. The method is independent of voltage, since only the ratio of the two phase voltages is required and this ratio is independent of the actual voltage used. The frequency need not be measured, provided means of checking its constancy are available; this can be conveniently done by any frequency meter. If good mica condensers are used the accuracy with which they are guaranteed by the manufacturers (say ¼ per cent) is more than sufficient for our purpose, since the actual value of the capacitance does not enter directly into the computations. Consequently, the main factor which limits the precision of the measurements is the accuracy of the calibration of the voltmeters and our ability to read the same. The probable error of the voltage ratio, including instrumental and observational errors, will not exceed 0.2 per cent.

Our experiments have indicated that the use of the iron-vane type of voltmeter is not very satisfactory for this purpose.

Appendix I

Proof that $\dfrac{V_2}{V_3} = R = 2 + \sqrt{3}$. for a pure sine wave: The following formula has been derived in a previous paper* for calculating the voltage to neutral for any branch of the star-connected circuit of Fig. 1.

$$I_p Z_p = E\left[a^{p-1} - \frac{a^0/Z_1 + a^1/Z_2 + \dots \dots a^{n-1}/Z_n}{1/Z_1 + 1/Z_2 + \dots \dots 1/Z_n}\right] \quad \text{(a)}$$

*Doggett. "Floating Neutral n-Phase Systems" TRANS. A. I. E. E., Vol. 42, 1923, p. 800.

where,
E is the numerical value of the impressed voltage to geometrical neutral.

$a = \cos 2\pi/\phi + j \sin 2\pi/\phi$ for counter clockwise rotation.

$a = \cos 2\pi/\phi - j \sin 2\pi/\phi$ for clockwise rotation.

ϕ = number of branches or phases.

Z_1 = impedance between 0 and 1 (see Fig. 1)

Z_2 = impedance between 0 and 2 (Fig. 1).

Z_n = impedance between 0 and n (Fig. 1).

p = 1, 2 or 3 for a three-phase system.

Assuming that the impedance of each meter is 1000 ohms resistance (inductance negligible†) and that of the condenser is also 1000 ohms (capacitive reactance), the reading of the voltmeter V_2 according to equation (**a**) is,

$$I_2 Z_2 = E\left[(-1/2 - j\sqrt{3}/2) - \frac{\dfrac{1}{-j\,1000} + \dfrac{-1/2 - j\sqrt{3}/2}{1000} + \dfrac{-1/2 + j\sqrt{3}/2}{1000}}{\dfrac{1}{-j\,1000} + \dfrac{1}{1000} + \dfrac{1}{1000}} \right]$$

$$= E\left[-1/2 - j\sqrt{3}/2 - \frac{j-1}{j+2} \right]$$

Rationalizing the last term, reducing and collecting,

$$I_2 Z_2 = \frac{E\,[-3 - j\,(6 + 5\sqrt{3}\,)\,]}{10} = V_2$$

Proceeding in a similar manner, the reading of V_3 is,

$$I_3 Z_3 = \frac{E\,[-3 - j\,(6 - 5\sqrt{3})\,]}{10} = V_3$$

Then the ratio R,

$$= \frac{V_2}{V_3} = \frac{-3 - j\,(6 + 5\sqrt{3})}{-3 - j\,(6 - 5\sqrt{3})}$$

Combining real and j terms of both numerator and denominator, and rationalizing,

$$R = 2 + \sqrt{3} = 3.732.$$

(Q. E. D.)

Appendix II

Proof of Equation (1). (General formula for calculating R for any number of harmonics of known percentage).

Notation.

E_1' = Fundamental component of voltage across V_2.

E_2' = 2^d harmonic component of voltage across V_2.

E_3' = 3^d harmonic component of voltage across V_2.

E_n' = n^{th} harmonic component of voltage across V_2.

E_1'' = Fundamental component of voltage across V_3.

E_2'' = 2^d harmonic component of voltage across V_3.

E_3'' = 3^d harmonic component of voltage across V_3.

E_n'' = n^{th} harmonic component of voltage across V_3.

Then,

$$R = \left[\frac{(100\,E_1')^2 + (\%\,2^d\,E_2')^2 + (\%\,3^d\,E_3')^2 + \ldots (\%\,n^{th}\,E_n')^2}{(100\,E_1'')^2 + (\%\,2^d\,E_2'')^2 + (\%\,3^d\,E_3'')^2 + \ldots (\%\,n^h\,E_n'')^2} \right]^{1/2} \quad (\mathbf{b})$$

Constants are worked out for the fundamental and fifth harmonic, in the following sample calculations, Using formula (**a**),

$$E_1' = -0.5 - j\,0.866 - \frac{-1+j}{2+j}$$ (Calculated in Appendix I)

Rationalizing the last term and collecting,

$E_1' = -0.3 + j\,1.466$

Combining real and j terms and squaring,

$(E_1')^2 = 2.24.$

Similarly,

$$E_1'' = -0.5 + j\,0.866 - \frac{1+j}{2+j}$$

$(E_1'')^2 = 0.161.$

Similarly, remembering that the phase rotation of the fifth harmonic is opposite to that of the fundamental*,

$$E_5' = -0.5 + j\,0.866 - \frac{-1+j\,5}{2+j\,5}$$

$(E_5')^2 = 1.794.$

$$E_5'' = -0.5 - j\,0.866 - \frac{-1+j\,5}{2+j\,5}$$

$$= -1.293 - j\,1.383$$

$(E_5'')^2 = 3.585$

Equation (**b**) can be transformed into equation (**1**) by factoring out the ratio for the fundamental sine wave, $(2 + \sqrt{3}.)$ The b constants are derived from the E'' constants in equation (**b**):

$$b_5 = (E_5'')^2 \times \frac{1}{0.161} = \frac{3.585}{0.161} = 22.3$$

The a constants of equation (**1**) are derived from the E' constants of equation (**b**):

$$a_5 = (E_5')^2 \times \frac{1}{0.161} \times \frac{1}{(2+\sqrt{3})^2}$$

$$= 1.794 \times \frac{1}{0.161} \times \frac{1}{13.92} = 0.80$$

†The inductance of the meters was found to be too small to affect these calculations appreciably.

Appendix III

The Harmonic Alternator. The various harmonic voltages were obtained by means of a special harmonic alternator. This machine consists of three three-phase a-c. generators of the revolving field type, one of which is a 15 kw., 60-cycle machine; the second has a capacity of 7½ kw. at 180 cycles, and the third, 3-kw. at 300 cycles. All three machines are mounted on the same bed-plate and have a common frame while the field coils of all machines are mounted on the same shaft. The armature of the 60-cycle machine is stationary, but the armature of the 180-cycle machine may be moved by means of a hand wheel through an angle corresponding to 360-electrical degrees, and the armature of the 300-cycle machine by similar means can be moved through an angle corresponding to 600-electrical degrees. The six terminals of the armature winding of each machine are connected to a switchboard so that the three-phase windings may be connected either in star or delta. The field control of each generator is independent of the other two fields. The machine is driven by a d-c. shunt motor and the field winding is separately excited.

U. S. HAS FIVE RADIO STATIONS TO EVERY ONE IN EUROPE

In the United States there are more than five times as many radiocasting stations as in all Europe. The total for the United States, according to the most recent statistics, is about 575, while the European total is but 110 radiocasting stations.

England leads European countries; Germany comes next; Spain is third.

By countries, the number of radio stations in Europe is as follows: Finland, eight; Norway, six; Sweden, one; Holland, one; Belgium, four; Irish Free State, two; Great Britain and the North of Ireland, twenty-one; Germany, twenty; France, twelve; Spain, thirteen; Portugal, none; Switzerland, four; Italy, six; Austria, five; Hungary, two; and Czechoslovakia, five.

TERMS OF APPLICATIONS FOR BROADCASTING LICENSE IN INDIA CHANGED

The Government of India has amended the conditions to be complied with by private enterprise in applying for a license to provide a broadcasting service in British India and Burma. It is now provided that at the expiration of the first five years the government will reserve the right to reduce the proportion of license payable to the company so that it will cover the cost of an adequate service, provide a reasonable reserve fund, and pay a dividend of 15 per cent per annum on the subscribed capital. This dividend was originally limited to 10 per cent. It has also been agreed that consideration will be given to applications which provide that importers shall pay a royalty on imported apparatus to the broadcasting company.

VOLTAGE FOR HOME USE

It is apparent that domestic loads have grown so large that serious attention must be given both to voltage regulation in the homes and to wiring in the homes. The houses are becoming miniature machine shops with a variety of motors and heating devices which are bound to cause voltage fluctuations if the wiring does no more than comply with the formal Underwriters' regulations. Some of the appliances, such as the electric refrigerators, automatic pumps, ventilating motors and oil-burner motors, have no respect for time or load and may start up at the peak period or at night when all lights are burning. These voltage fluctuations are annoying because of their effect on the lights, and they may become more so as relays and controls are developed and used for household applications.

The utility may enlarge transformers and secondary distribution copper and yet not improve the situation materially. The answer to the problem lies in the wiring of each home, the motors used on devices and the development of some kind of house voltage regulator.—*Electrical World.*

Current Limiting Reactors
with Fire-Proof Insulation on the Conductor

BY F. H. KIERSTEAD[1]

Associate, A. I. E. E.

Synopsis.—*In a previous paper, tests were described which proved conclusively that if conducting material were lodged between the turns of a reactor having bare conductor, the reactor would flashover at the instant a failure occurred on the circuit in which the reactor was placed. In this paper, tests are described which were made during the development of a proper insulation for the conductor of reactors.*

Short Circuit Tests. *Reactors tested consisted of one reactor with enameled conductor and two reactors with asbestos insulated conductor; one having a thin covering of asbestos; the other a thicker covering.*

The reactor with enameled conductor flashed over during the first short circuit test. That with a thin covering of asbestos stood one short circuit and arced over in the second short circuit. The reactor with the thick covering stood many short circuit tests without any failure or sign of distress.

These tests established the fact that thin insulation on the conductor will not prevent such failures, even though it has sufficient dielectric strength to withstand the voltages placed across it for the reason that the magnetic force exerted on iron and steel objects will cause them to break through thin insulation. On the other hand, thick insulation will adequately protect the reactor from failure due to foreign substances.

Thermal Tests. *Thermal tests on the asbestos insulation established the following facts:*

First: That this insulation does not smoke excessively at temperatures below 350 deg. cent.

Second: That it does not burn even at temperatures of melting copper.

Third: That its insulation and mechanical strength is not appreciably affected when heated rapidly as high as 350 deg. cent.

Thermal Capacity. *The thermal capacity of the conductor is affected by the insulation, as follows:*

First: Under the effects of extremely high short circuit currents for a very brief interval, the thermal capacity is not affected by the asbestos.

Second: With a moderate short-circuit current for a longer length of time, the thermal capacity of the insulated conductor is increased due to the storage of heat in the insulation.

Third: During normal operation, at rated current, the temperature rise of conductor is increased due to the drop in temperature in the insulation.

Costs. *The asbestos insulation increases the cost of the reactor directly by the addition of the cost of the insulation itself and indirectly by making it necessary occasionally to increase the size of the conductor. However, this increase in cost is not a large percentage of the total cost of the reactor.*

* * * * *

IN a previous paper entitled, "The Design, Installation and Operation of Current Limiting Reactors," presented by Kierstead and Stephens, at the Annual Convention of the A. I. E. E., July 1924, short-circuit tests upon reactors were described. These tests proved conclusively that if conducting material were lodged between the turns of a reactor having bare conductor, the reactor would flashover at the instant a failure occurred on the circuit in which it was placed. In other words, if a piece of metal, such as a nut, bolt, washer, or screw drops or is magnetically drawn into a reactor and becomes lodged between two of its turns, there may be no indication of its presence in the reactor during the normal operation of the circuit but at the instant of a fault on this circuit, the voltage between these turns jumps to many times its previous value, incipient arcs shoot out at the points where the metal bridges between turns and this is followed instantly by a complete flashover of the reactor. Since that paper was presented, an investigation has been carried out to determine a suitable insulation for the conductor of reactors to prevent such foreign conducting material causing reactors to flashover. The purpose of this paper is to describe the tests which were made to determine the kind and thickness of insulation to be used.

The primary requisites of such insulation are as follows:

First: It must have sufficient dielectric and mechanical strength to prevent short circuits between turns by foreign conducting materials.

Second: It must conform to the well established practise of using only fire-proof materials in the construction of current-limiting reactors.

The first part of this paper is devoted to a description of the short-circuit tests made upon reactors to determine the insulation to be used, while the second part describes thermal tests made to determine the fire-proof characteristics of the insulation.

Short-Circuit Tests

Enamel and asbestos were chosen as the most suitable insulations because of their fire-proof characteristics. One reactor was built with enameled conductor and two reactors with asbestos-insulated conductors; one having a thin covering of asbestos, the other a thicker covering. The reason for making tests on reactors with these different insulations was to determine the thickness of insulation necessary.

The short-circuit tests made upon the reactors consisted of bringing up the terminal voltage on a 26,700-kv-a., 25-cycle generator to 13,200 volts, and then

1. Transformer Engineering Dept. General Electric Company, Pittsfield, Mass.

To be presented at the Midwinter Convention of the A. I. E. E., New York, N. Y., February 8-11, 1926.

short-circuiting two of its phases through the reactor under test. All three reactors were the "cast-in concrete" type, rated: 60 cyc es, 68 kv-a., 229 volts, 300 amperes, and were designed for use in introducing 3 per cent reactive drop in a 13,200-volt circuit. A diagram of the connections used in the tests is shown in Fig. 1. The tests made upon the different reactors are described under the following headings: (A), Reactor with Enameled Conductor. (B), Reactor with

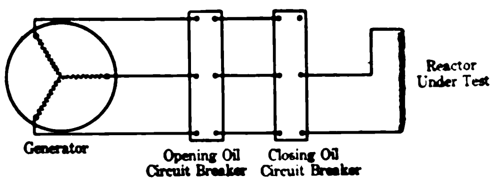

FIG. 1—DIAGRAM OF CIRCUIT USED WHEN MAKING SHORT CIRCUIT TESTS

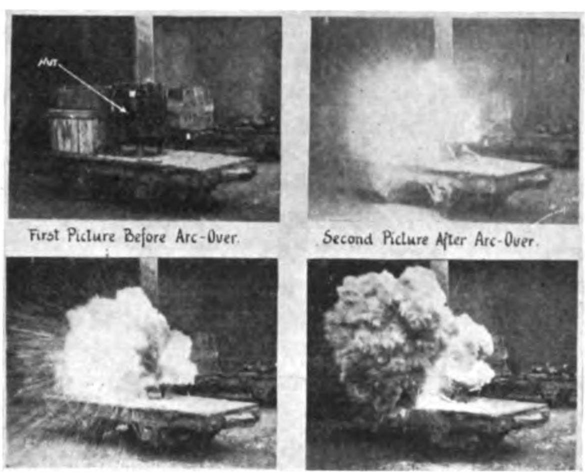
a Thin Covering of Asbestos Insulation on the Conductor. (C), Reactor with a Thick Covering of Asbestos Insulation on the Conductor.

A. Reactor with Enameled Conductor. The conductor of the reactor on which these tests were made was enameled and the purpose of the tests was to determine whether the enamel would afford sufficient insulation to prevent a flashover if conducting material bridged between the turns.

The test was made by placing a steel nut between



Third Picture After Arc-Over Sixth Picture After Arc-Over

FIG. 2—REPRODUCTION FROM MOTION-PICTURE FILM TAKEN DURING SHORT-CIRCUIT TESTS ON REACTOR WITH ENAMELED CONDUCTOR

Arcing due to steel nut. *Enamel did not afford* sufficient insulation.

two adjacent turns of the reactor midway between the top and the bottom and then short-circuiting the generator through the reactor. The reactor as it appeared immediately before the test is shown in the upper left hand corner of Fig. 2 which is an enlargement of a portion of the motion pictures taken during these tests. The nut is painted white and is clearly visible in the photograph.

Although the reactor had previously been tested several times under short circuit (without giving any indication of distress), after the nut was placed in it, it flashed over during the first half cycle of the first short-circuit test. This test proved that enamel is not sufficient insulation to prevent a flashover, due to foreign conducting material.

The nut was thrown violently from the reactor to a distance of about 30 ft. where it struck a board and dented it to a depth of $\frac{1}{16}$ in. In short-circuiting a portion of the reactor winding, the nut carried a current in opposition to the main current in the reactor and the magnetic force between these opposing currents was probably the propelling force which expelled the nut. In this respect, foreign conducting material partakes of lifelike characteristics in that it may cause a lot of damage and then clear out and leave no clue as to the cause of the damage.

B. Reactor with a Thin Covering of Asbestos on the Conductor. The reactor on which the tests under this heading were made had a thin wall of asbestos covering

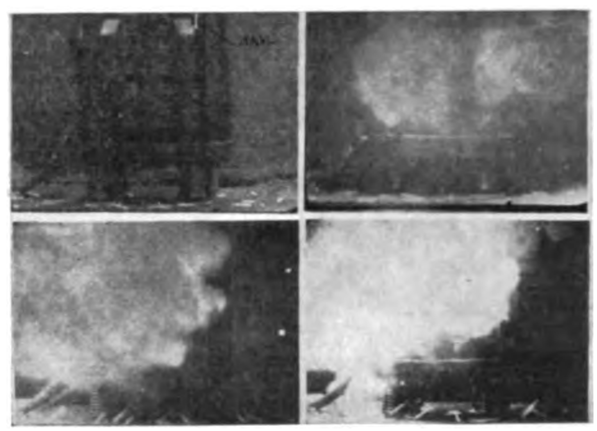


FIG. 3—REPRODUCTION FROM MOTION-PICTURE FILM TAKEN DURING SHORT-CIRCUIT TESTS ON REACTOR WITH CONDUCTOR INSULATED WITH THIN ASBESTOS

Arcing due to nail. Asbestos *was not thick enough* to afford sufficient insulation

on its conductor. It received the same tests as those applied to the preceding reactor, except that in this case, a nail was tied to the conductor so as to span between the outside turns of the upper two layers. The reactor with the nail attached is shown in the upper left hand picture of Fig. 3 which is a reproduction of a portion of the motion pictures taken during this test. This reactor stood the first short-circuit test without showing any visible signs of distress but flashed over during the first half cycle of the second test. The other pictures shown in Fig. 3 immediately followed the instant of flashover.

These tests showed that while the thin asbestos covering afforded more protection than the enamel (since it was able to pass through one short-circuit test without failure) still it was not thick enough to adequately protect the reactor from foreign conducting material.

C. Reactor with a Thick Covering of Asbestos Insula-

tion on Its Conductor. The reactor tested next had thicker asbestos insulation on its conductor than that of the preceding reactor. Many short-circuit tests similar to those previously described were made on this reactor with steel bolts and nuts variously located in an endeavor to make the tests as severe as would be encountered in actual service. In this reactor, however, the insulation on the conductor was sufficient to afford the conductor adequate protection from the foreign conducting material to which it was subjected. Some of the reproductions of the motion pictures taken during these tests are of interest, for the reason that having been taken at the rate of 125 pictures per second they show the movement of loose steel objects around and in the reactor. Fig 4 shows four pictures taken when a loose bolt was placed on the winding midway between the top and the bottom. The pictures are consecutive in the order in which they are numbered. The first picture shows the bolt resting on the winding. The next picture taken 1/125 of a second later, shows one end of the bolt raised up by magnetic force so that it is striking against one of the turns above while the other end is resting on one of the turns below. The pictures also show nails which had been strewn on the floor near the reactor being lifted by the magnetic field. Fig. 5 shows a similar group of pictures except that the bolt is first resting on top of the winding but is later pulled down so as to span between the top and next adjacent layers. The picture again shows nails being lifted from the floor. In Fig. 6, the bolt was placed so that it spanned the space between the top and next adjacent layers before the test and did not move during the test. The chief interest in these latter pictures is that they show nai s being lifted from the floor and being drawn into the windings with considerable force.

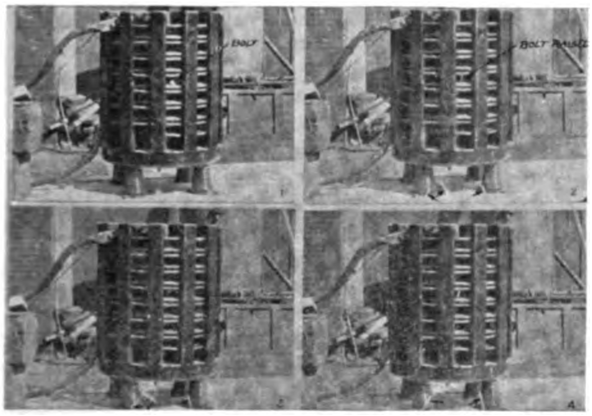

Fig. 4—Reproduction from Motion-Picture Film of Short-Circuit Tests on Reactor with Conductor Insulated with Thick Asbestos Insulation. Showing Bolt in Winding being raised and Nails being drawn toward Reactor by Magnetic Field. Arrows Indicate Nails

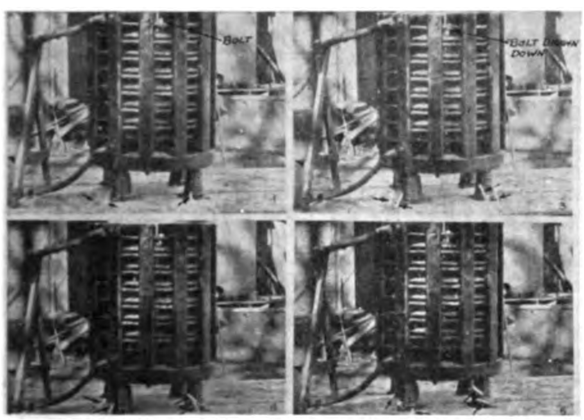

Fig. 5—Similar to Fig. 4 but shows Bolt being drawn by Magnetic Field from Top Layer to a Position Bridging between the Two Top Layers. Arrows Indicate Nails being drawn toward Reactor

The reproductions of the motion pictures show that the magnetic field of a reactor exerts a considerable force on magnetic substances. Therefore, the insulation on the conductor not only must be strong enough to withstand the electric stress which may be placed upon it, but must also be strong enough mechanically to withstand without injury, the cutting or piercing action of iron and steel objects when drawn against it by the magnetic force. It was this latter action that was the primary cause of the failures of the first two reactors.

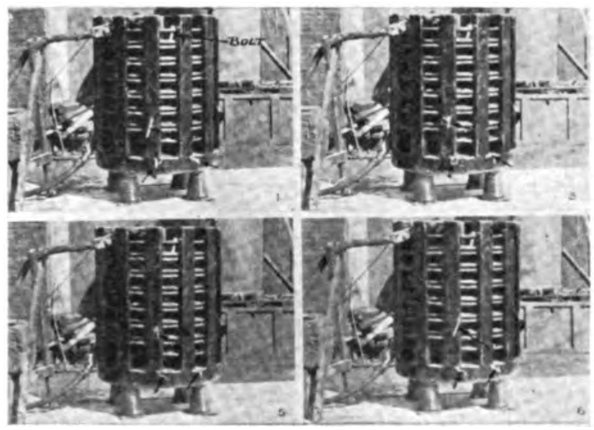

Fig. 6—Similar to Fig. 5 but shows Nails being drawn from Floor into Reactor by Magnetic Field. Arrows Indicate Nails

The thicker insulation on the last reactor tested had sufficient resilience to resist the blows delivered to it by the steel objects without being cut and in addition being thicker, could be indented to a greater depth without being pierced through to the conductor. Therefore, it was able to withstand the many short circuit tests it was subjected to without failure.

Summarizing, the foregoing tests established the following facts:

First: That a reactor with bare conductor will flashover during a short-circuit if conducting material is lodged in its winding.

Second: That thin insulation on the conductor will not prevent such failures, even though it has sufficient dielectric strength to withstand the voltages placed across it, for the reason that the magnetic force exerted on iron and steel objects will cause them to break through thin insulation.

Thermal Tests

Having established the thickness of asbestos insulation required to prevent electrical failures in reactors,

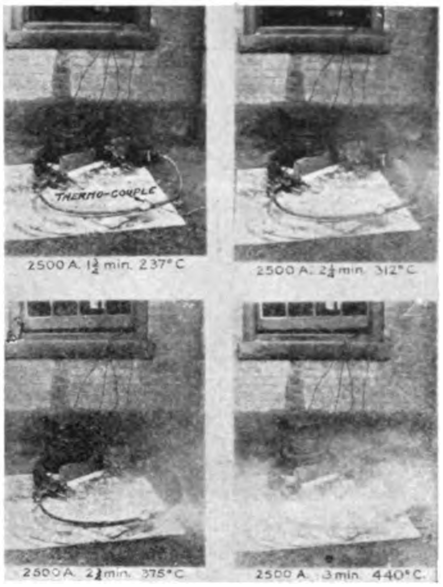

Fig. 7—Successive Pictures taken during High Temperature Test on Asbestos Insulated Cable

it was next required to determine if this insulation was fire-proof.

Test to determine whether the insulation would burn were made on 5 ft. lengths of 250,000-cir. mil. cable insulated with asbestos insulation. The equipment used in making these tests is shown in Fig. 7 and is comprised of a transformer for use in obtaining high current, a current transformer for measuring the current, and a thermo couple placed in the center of the cable. The tests consisted of holding 2500 amperes in the conductor until it melted. The amount of smoke emitted from the cable during these tests is more clearly shown by Fig. 7 than can be described. The figure shows that smoke just began to make its appearance at 312 deg. cent. while it became most dense at 440 deg. cent. As the temperature increased above this figure, the denseness of the smoke gradually decreased and had discontinued before the melting point was reached. At no time did the insulation show any tendency to burn. After the cable had been raised to the melting point of copper, the binding materials which held the asbestos fibers together had been destroyed and as a result the mechanical strength of the asbestos was practically zero.

The next tests were made to determine to what temperatures the cable could be raised without damaging the asbestos insulation.

It was felt that the insulation should be cabable of resisting the effects of having the conductor rapidly heated up to a temperature of 350 deg. cent. without injury to its mechanical or electrical strength. Therefore, a test was made by holding 2500 amperes in the cable until 350 deg. cent. was reached. This required about 2½ minutes. The insulation showed no indication that its mechanical strength had been injured by this test and the puncture tests showed that its insulation strength had not deteriorated.

Summarizing, the foregoing high temperature tests have established the following facts:

First: That this asbestos insulation does not smoke excessively at temperature below 350 deg. cent.

Second: That it does not burn even at temperatures of melting copper.

Third: That its insulation and mechanical strength is not appreciably affected when heated rapidly to temperatures as high as 350 deg. cent.

In actual service with the reactor carrying full short-circuit current, there will be no tendency for the reactor to smoke or the insulation to be injured for the reason that the current will be interrupted by the circuit breaker long before the temperature of the conductor has risen to 350 deg. cent.

The question quite naturally arises as to what effect the asbestos insulation will have on the thermal capacity of the conductor. Of course, if a short circuit is maintained for such a brief period of time that practically all the heat is stored in the copper then the insulated conductor will rise to practically the same temperature as the bare conductor. On the other hand, if the short circuit continues until an appreciable part of the heat generated is dissipated, there will be a period during which the flow of heat from the insulated conductor into its insulation will be more rapid than the flow of heat from the bare conductor into the air. During this period, the insulated conductor will be cooler than the bare conductor.

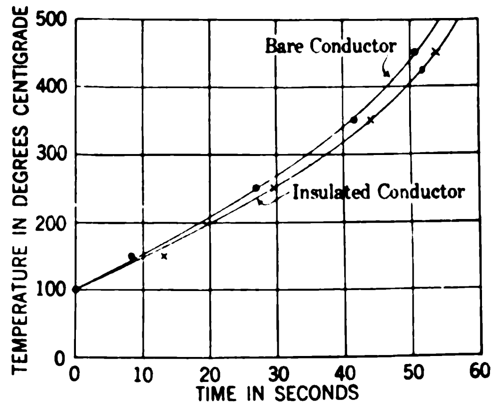

Fig. 8—Comparative Rate of Heating of Bare and Insulated Conductor for Short Periods

The accuracy of the above statement was checked by comparative tests on bare and insulated 250,000-cir. mil. cable. The tests consisted in holding 4000 amperes in each cable and measuring the time required for the conductors to rise to a given temperature. The temperature of the conductor was measured by thermo couples soldered to the conductor. In Fig. 8, the results of these tests are plotted. It will be noted that in all the tests the bare conductor was the hottest.

During the normal operation of the reactor when it is carrying rated current continuously, all the heat generated is, of course, dissipated and naturally the insulated conductor becomes the hottest. It has been found, however, that although asbestos is one of the best insulators of heat, the asbestos covering used on the conductors for reactors does not impede the flow of heat from the conductor to a great degree. The explanation for this is that the asbestos fibers are so

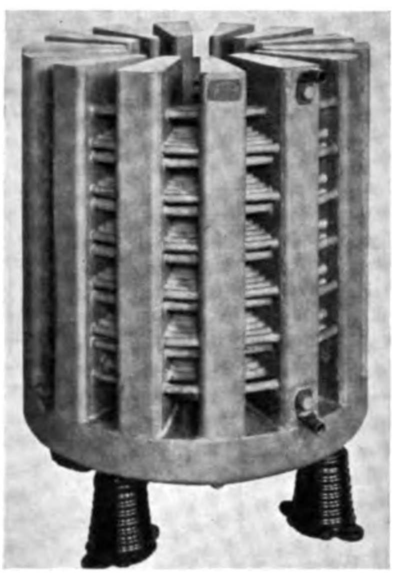

Fig. 9—"Cast-In Concrete" Reactor with Conductor Insulated with Asbestos Covering

densely formed around the conductor that the rate of conduction through them is many times more rapid than through the forms of asbestos used for heat insulation.

As has been shown in the preceding pages, the use of thick asbestos insulation removes the danger of flashover that a reactor without such insulation is subject to and yet does not affect its fire-proof qualities or the simplicity of its construction. Fig. 9 shows a reactor with asbestos insulation on its conductor. It will be noted that it is of the same general construction that has typified the "cast-in concrete" type of reactors for the past ten years. The asbestos fibers are closely and firmly woven on the conductor. They are treated with a compound which makes them very strong and able to resist cutting or tearing very tenaciously.

Insulating the conductors of reactors with asbestos increases their cost directly by the addition of the cost of the insulation itself and indirectly by making it necessary occasionally to increase the size of the conductor to compensate for the reduction in the rate of heat dissipation caused by the insulation. However, the cost of the insulation is not a arge percentage of the total cost of the reactor and the additional cost of a larger conductor is greatly offset by the reduced operating charges resulting from the reduction in losses occasioned by use of a larger conductor. Furthermore, as stated above, the asbestos covering has not been found to impede the flow of heat from the conductor to a great degree. These cost increases, therefore, are slight and will make no material difference in the present economies of a system which includes reactors.

In conclusion, attention is again called to the fact that the tests described in this paper have proven that any conductor insulation, which will afford adequate protection to a reactor from foreign conducting material not only must have sufficient insulation strength to stand the voltage stresses placed upon it, but also must have sufficient mechanical strength to withstand without injury the cutting and piercing action of iron or steel objects that may be drawn against it by the magnetic field of the reactor. Furthermore, the tests have shown that the asbestos insulation which has been developed for reactors affords protection from foreign conducting materials without sacrificing the fire-proof qualities which modern central station practise demands.

The author wishes to acknowledge the valuable assistance which Mr. L. P. Burgess rendered when the tests herein described were made.

PREVENTION OF DETERIORATION OF VULCANIZED RUBBER

It has been known for some time that deterioration of vulcanized rubber by oxidation can be delayed by the use of substances which are themselves easily oxidized and which act as anticatalysts of oxidation. Recently two of the largest rubber companies simultaneously patented almost identical antioxidants. A sample of the material received by the Bureau of Standards has been employed in rubber compounds which were then subjected to an accelerated aging test. The bureau's results substantiate the claim that the durability of rubber with respect to the effects of light and heat can be increased about 600 per cent.

Practical Aspects of System Stability

BY ROY WILKINS[1]

Associate, A. I. E. E.

Synopsis—*During the past few years there has been much discussion regarding the behavior of long transmission lines under transient conditions, such as flashovers, short circuits, arcs and grounds which would tend to make them unstable, but unfortunately this discussion has been largely theoretical due to the absence of any actual operating data upon which to base assumptions. It has only been recently that an opportunity has been afforded to make field tests on one of the two existing 220-kv. systems and the results of such a series of tests made on the system of the Pacific Gas and Electric Company are presented in the paper.*

This is the first instance where tests of this nature have been attempted and the lack of proper testing equipment proved a serious handicap. It was necessary to develop a special high-speed oscillograph wattmeter, a high-speed oscillograph filmholder and a pilot generator. Moreover the technique of testing was developed so that it was possible to secure oscillographic records 200 mi. apart by telephone signal.

The tests established the following important facts:

1. System stability as a problem is inextricably entangled with operating economics, and cannot be handled solely as a problem in design, except for very simple cases. 2. For any adequate conclusions to be reached much more fundamental data is necessary. 3. Requisite equipment for obtaining such data is not now available. 4. Studies of models and artificial transmission lines are not adequate because too little is known about the relative importance of the several factors to allow intelligent duplication. 5. Proper relay equipment and action is vital. 6. Oil-switch operation is an important factor. 7. Only a certain part of the stored energy of a system is available in any given case of trouble. 8. Operating distribution of excitation current is one of the major problems.

As transmission networks have grown in economic importance and kilowatt capacity, the problem of stable operation has assumed an increasingly greater importance, culminating in 1922-23 in studies of the proposed long distance transmission of large blocks of power to important market centers in the Atlantic States. In the consideration of these proposals a detailed study of system stability was considered essential. Preliminary theoretical analysis of the several problems encountered was presented at the Midwinter Convention of the Institute in 1924, and showed a decided lack of agreement on the methods of attack and the results obtained.

Opportunity was afforded to carry out tests on one of the two existing transmission systems having long 220-kv. transmission lines feeding a large load network, consequently a series of tests were carried out early in 1925 on the transmission system of the Pacific Gas and Electric Company to secure definite operating data on several of the points in question. The data accumulated on the test was an attempt to determine what was required on a network in order to predict its characteristics with respect to stability. It cannot be too strongly emphasized that data secured is for a specific condition on a given system and that such lack of agreement as evidenced in the calculations made in the past is due not so much to differences in mathematical treatment as to differences in assumptions made in regard to the relative importance of the several factors.

In the tests these factors are naturally included in their proper proportion and place, and any calculation made for the same conditions, to be at all adequate, must presuppose a thorough knowledge of all of the factors as well as of their relative importance. Artificial lines and miniature equipment cannot be substituted without such knowledge, for at best the results are

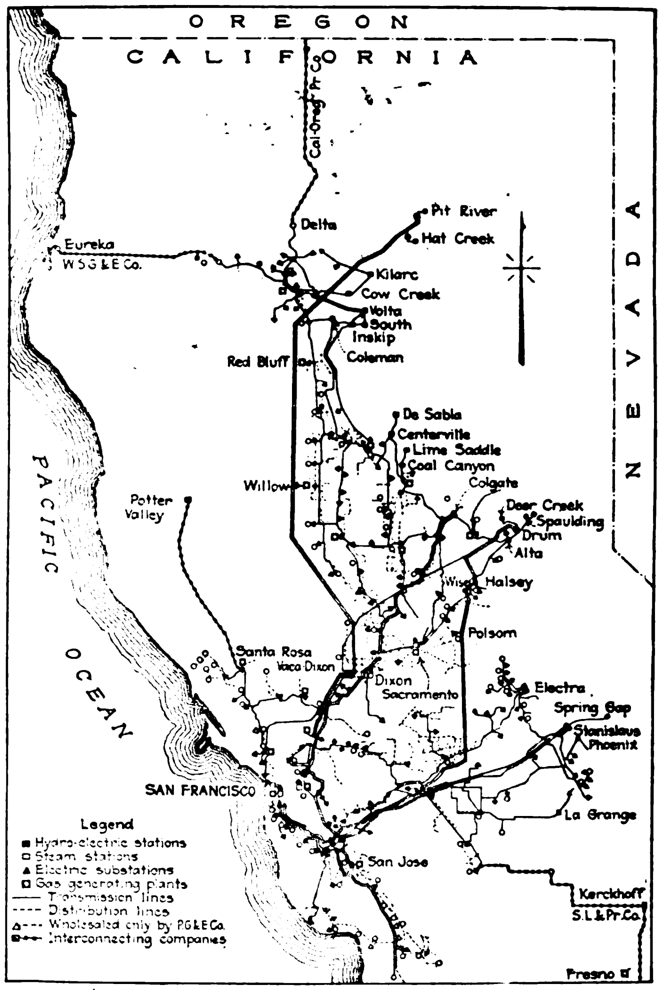

Fig. 1—System Diagram, Pacific Gas and Electric Company

only a reflection of the assumptions made. The difference between values in tests on an actual system and

1. Assistant Engineer, Division of Hydroelectric and Transmission Engineering, Pacific Gas and Electric Company, San Francisco, Calif.

To be presented at the Midwinter Convention of the A. I. E. E., New York, N. Y., February 8-11, 1926.

calculated or miniature equipment tests represents the numerical value of errors due to such assumptions.

Given enough fundamental data on the network during trouble, the effect of such trouble may, with much patience and persistence, be calculated for very simple cases, but at least for the present the actual quantitative values for this fundamental data must be measured to insure any degree of accuracy in the final result. The tests as carried out are an attempt to evaluate at least a part of the unknown quantities, in order that the necessary assumptions for calculation may be at least reasonably correct.

Outline of Tests

The points on the system of the Pacific Gas and Electric Company selected for the tests were Pit No.1

TABLE I

NETWORK DATA AT TIME OF TEST

202 mi. of two-circuit 220-kv. line connected to three power-houses and one substation.
607 mi. of 110-kv. line connected to six power-houses and 10 substations.
2039 mi. of 60-kv. line, connected to 19 power-houses and 162 substations.
8434 mi. below 60-kv. line connected to 100 substations.
160 mi. of underground.
27—Hydro plants having 69 units and 317,975 kv-a. capacity.
4—Steam plants having 12 units and 142,000 kv-a. capacity.
2—20,000 kv-a. synchronous condensers.
2—12,500 kv-a. synchronous condensers.
1—7500 kv-a. synchronous condensers.

There were also, connected and operating in parallel, the Great Western Power Company, having
196 miles of 165-kv. line.
150 mi. of two circuit; 30 mi. of one circuit of 100-kv. line
520 mi.—below 60 and above 20-kv. line, with:
2—Hydro plants having nine units, 131,000 kv-a.
4—Steam plants having nine units 30,800 kv-a.
3—Synchronous Condensers having three units, 60,000 kv-a.

The California Oregon Power Company having 200 mi. of 66 kv.
513 mi. of 60 and 38 kv. with
10—Hydro plants having 16 units, 56,160 kv-a.

The Truckee River Power Company with five hydro plants and 8650 kv-a.

The Snow Mountain Power Company with,
107 mi. of line below 60 kv. and above 30 kv.
1 Hydro-Electric plant having 1 unit and 6400 kv-a. together with several smaller distributing networks to which the Pacific Gas and Electric Company wholesales power.

There was on the Pacific Gas and Electric Company system approximately 1,500,000 h. p. connected load, of which the average yearly distribution is:
35.0 per cent—Commercial and domestic lighting and heating.
13.5 per cent—Agricultural power (mostly centrifugal pumps).
3.0 per cent—Mining-power induction motors.
21.0 per cent—Manufacturing power.
8.0 per cent—Railway power.
19.5 per cent—Miscellaneous power.

The interconnected companies have roughly the same connected load per kv-a. generating capacity and the same general distribution of load.

For the Pacific Gas and Electric Company the monthly load factor in December is about 61 per cent, for August about 73 per cent, and the yearly load factor 62.5. The daily load factor is 65-79.

Power-House, the generator end of the two 202-mi., 220-kv. Pit transmission lines, and Vaca-Dixon Substation, the receiver end of these lines (see Fig. 1). Physical data on the system network at the time of the test is given in Table I.

Pit No. 1 Power-House has installed two 35,000-kv-a., 3-phase, 60-cycle, 11,000-volt generators driven by 40,000-h. p. Francis turbines, each having a $W R^2$ of 7,365,000 lb. ft. On the same 11,000-volt bus is also connected the two Hat Creek plants, each having one 12,500-kv-a. turbine-driven generator, with 2,800,000 $W R^2$, 6600-volt, 3-phase, 60-cycle connected through 6600- to 60,000-volt transformer banks and approximately five mi. of double-circuit tower lines to a step-down bank 60,000/1100 at Pit No. 1.

Connecting Pit No. 1 with Vaca Substation is a 202-mi. double-circuit 220-kv. transmission line,[2] through two 11,000- to 220,000-volt delta Y-connected 50,000-kv-a. transformer banks at Pit No. 1 and through two 200,000/110,000/10,460-volt 50,000-kv-a. banks at Vaca Substation. The Vaca transformer banks are Y-connected auto-transformers with a delta-connected tertiary from each of which is operated a 20,000-kv-a., 11,000-volt synchronous condenser. At Vaca the power enters the 110-kv. network as shown in Fig. 1. At the time of test, one line was operating at 220-kv. and one at 125-kv., one bank at Pit No. 1 being temporarily reconnected and the line going to the 110-kv. terminal of the bank at Vaca instead of the 220-kv., the 110-kv. is designated as No. 1 and the 220-kv. as No. 2.

The Following is an Outline of the Schedule of Tests.

I. *a.* Start condenser at Vaca.
   b. Trip one condenser at Vaca.

II. Run both generators at Pit, one leading and one lagging.
   a. Trip one.

III. Running both generators at Pit.
   Trip one at ¼ load.
   " " " ½ "
   " " " ¾ "

IV. Line switching at Pit.
   a. Switch out No. 2 line at Pit at 220 kv.
   b. " " " " " " Vaca at 220 kv.
   Vary and repeat.

V. Ground No. 2 line through fuse first tower out from Vaca bus.
   Repeat.

Test Equipment

A description of the equipment used in making the tests is given in Table II. The six-element oscillograph used at Pit No. 1 was a Westinghouse portable permanent magnet type equipped with a special film holder using 6½ in. films 24 ft. long and running up to speeds of about 1 in. per cycle. The 3-element was also a Westinghouse portable permanent magnet type with a special holder, handling films 3¼ in. by 15 ft. at speeds

2. See TRANSACTIONS A. I. E. E., 1924, Page 1148, Corona Loss Test.

teristics and a natural period of about $^1/_{20}$ second; developed by the Westinghouse Company for the test, see Fig. 2, calibration Fig. 3.

There were three of these 3-phase meters in one case,

all working on the same film. Timing was accomplished by interrupting the beam of light from one meter for a short time every $^1/_{10}$ second by means of a small synchronous motor, giving indications shown as small gaps in the record of one meter on the film. The films were 3¼ in. by 55 in. and had a speed up to 15 in. per second. For measuring the absolute change in phase position a small motor-generator set comprised of a d-c. motor and an alternator with a fly-wheel was run from the station storage battery. There was

mounted on the generator, with its rotor mounted on the end of the generator shaft, a remodeled "Ford" magneto having the same number of poles as the main generator, (see Fig. 4). This magneto having no load, gave a true record of the field or rotor position at all times and its wave is referred to as the pilot generator voltage. There was also installed a mechanical recording device on the turbine governor giving governor travel.

The 3-element oscillograph used was a Westinghouse electromagnet portable oscillograph, having in addition to the three elements, a single-phase wattmeter using the fourth prism and the same film. The film was 3¼ in. by 55 in. and was run at speeds up to 15 in. per second. There were also two special polyphase graphic wattmeters using high speed charts driven by synchronous motors. All of the data at Vaca was taken by telephone signal from Pit No. 1 as was also the switching. This was satisfactory enough that the two sets of equipment 200 mi. apart were able to catch each test on the standard film within one-quarter of its travel.

transient and a speed sufficient to make individual cycles available for angular measurement.

Fig. 5 represents that portion of a 24-ft. film during which switching took place, for opening a 220-kv. line at Pit No. 1.

Fig. 6 is a portion of a 15-ft. film taken at Pit No. 1 Power-House during one of the artificial flashovers at Vaca Substation.

This shows the start of the flashover, the point at which the line cleared at Vaca, the point at which Pit No. 1 cleared, and on the original film 7 or 8 seconds record thereafter.

Fig. 7 shows a portion of a film of an oil circuit breaker opening a 220-kv. line lightly loaded. There are shown the three line currents and the residual current.

This record indicates the phase balance action between phases when opening a polyphase circuit; the current ruptured by the last circuit breaker shows nearly four times the original phase current.

Fig. 8 is the record by the oscillographic wattmeter of switching out the 220-kv. line at Pit No. 1 carrying 24,000 kw., thereby increasing the load on the 110-kv. line from 12,000 to 35,000 kw.

The generator instead of dropping from 32,000 kw. to 12,000 kw. drops only about 3000 kw., and that only after $^3/_{10}$ second.

Fig. 9 shows these wattmeter records plotted on a common scale.

Fig. 10 shows the reverse process, *i. e.*, closing the 220-kv. line at Pit No. 1 and picking up load from the 110-kv. line. This action is much more severe, takes place faster and causes more outside disturbance than the opening of a line.

Fig. 11 shows this plotted to a common scale.

Previous articles[3] on this subject have considered that

CHARACTER OF DATA

It was necessary that the preliminary data be taken comparatively cheaply and without undue disturbance to normal operation, that the oscillographic records have a length in time sufficient to cover all of the

when one of two parallel lines was opened, the output of the station feeding them dropped instantly to the load on the remaining line while the prime mover stored

3. See J. P. Jollyman, JOURN. A. I. E. E., Sept., 1925, p. 950, Fig. 4. C. L. Fortescue, JOUR. A. I. E. E., Sept., 1925, p. 955, Fig. 4.

energy in the fly-wheel effect of the generator, releasing it to cause as great an overswing of output as the drop represented in kw. hrs.

This view assumes that the energy absorbed must be shown in a change in velocity of the generator rotor caused mechanically by the prime mover, and that there is no damping action. The curves demonstrate that such is not the case and also that closing a line more nearly approximates it than opening one.

In the writer's opinion the same effect is obtained by changing the power-factor of the generator load because this gives the same shift of the generator rotor and rotating armature field as a change in rotor velocity would, with the addition that it can take place as fast as circuit conditions permit. For a generator carrying load, the field poles occupy a certain position with respect to the rotating armature flux, any increase in load causes the armature flux to lag behind the field poles, *i. e.*, to come from the trailing edge of the pole if the power is constant. Given a constant load, a change in power-factor accomplishes the same result.

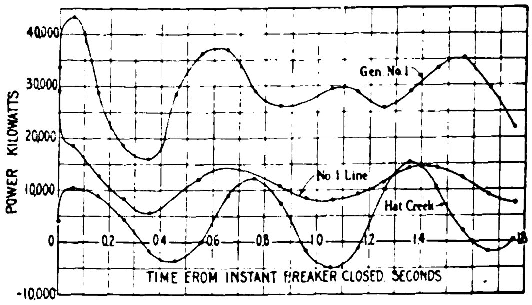

Fig. 11—Fig. 10 Plotted to a Common Scale for All Elements

With such a pilot generator as used at Pit No. 1, these changes may be observed on an oscillograph. Any such shift in armature flux position absorbs from or delivers energy to the field structure rotating as a fly-wheel and it must take place before there is any tendency to change the speed of the prime movers.

The rate at which energy can be absorbed depends on the electrical characteristics of the circuit involving a great number of variables among which is oil-circuit breaker action. No circuit breaker at present in use interrupts a circuit instantly, neither do they interrupt all three phases simultaneously because they interrupt the circuit at the zero point on the current wave of an arc of variable length. When closing the contacts make contact mechanically at a predetermined position and the action is, therefore, much quicker and more uniform. All of these things cause a change in wave shape in both current and voltage in all of the interconnected circuits. In most of the tests described, the speed and length of film were sufficient to permit angular measurement to be taken.

It was found that the change in wave shape was sufficient to materially affect the results.

On one of the tests, shown by Fig. 12, the several

Table III, by S. B. Griscom of Westinghouse Electric and Manufacturing Company, gives the numerical values of these harmonics and angles in this particular test.

Fig. 18 shows an oscillographic wattmeter record of an artificial flashover on the 220-kv. line under normal operating conditions caused by closing an air switch; Fig. 19, on a string of insulators over which a 10-ampere fuse had been placed.

This gave an arc from one phase to ground over an insulator string cleared by relays in the normal manner under actual operating conditions.

Oscillograms of current, voltage, etc., were taken both at Pit No. 1 Power-House and Vaca during such a flashover. Fig. 20 and Fig. 21 are illustrations of such an arc.

At Vaca, in addition to the oscillographic record of current and voltage, there was a single-phase wattmeter record of the residual power, *i. e.*, voltage across the corner of an open delta and the common return of the three current transformers connected in Y.

Fig. 22 shows the record for two such flashovers.

Too strong emphasis cannot be placed on the statement that any such data is for a network in operating condition, and that there are a great number of unknown variables involved, the determination of any one of which is a problem of major importance, worthy of a complete discussion in itself.

The stability problem is inextricably enmeshed with system operating economies and in the greater number of cases the limitations are as much operating difficulties as engineering design. It is not possible to economically build and operate a complete superpower network for ideal conditions at the present time. Such networks grow naturally from the demand for more and better power service, and are made up of interconnected existing networks too valuable to junk outright. They must be adapted to operate together.

NECESSARY CONSIDERATIONS

Trouble, Relays and Switching. On any major line in a network similar to the one on which these tests were made, it is *absolutely essential* to clear arcs quickly; so quickly in fact that neither governors nor automatic voltage regulators of the present type can act sufficiently to make any material change before the line is cleared. With proper relay action a line can be cleared of an arc over an insulator string so promptly that it has been almost impossible to locate the point of trouble. If an arc is left unchecked for anything like the time required for the network to reach a stable condition, the wire in trouble is melted or sufficiently annealed to cause it to part mechanically. Arcs on high tension lines generally strip the top and bottom units of an insulator string first and then cause a burn sufficient to drop a conductor. On any line of 220 kv. the conductor size and stringing tension make it necessary to have heavy equipment, usually gasoline-driven trucks, to handle any work done on the conductors. For this reason it is necessary to clear positively and quickly any trouble. Failure to do this means not a momentary interruption but hours, or more probably days, until the necessary heavy equipment can be assembled at the point of trouble for line repairs.

Experience has shown that the only practical procedure is to clear the smallest practical section of the network around the trouble in the shortest possible time.

TABLE IV

ANALYSIS OF RELAY OPERATION ON THE 220-KV., 110-KV., AND 60-KV. TRANSMISSION NETWORK OF THE PACIFIC GAS AND ELECTRIC COMPANY FOR 1923 AND 1924

1		2		3		4		5		6	
						Incorrect relay operations					
Total operations involving relays		Correct relay operations		Relay failures		Due to relay		Due to external causes		Question-able relay operations	
Year	No.	No.	Per Cent	No.	Per Cent	No.	Per Cent	No.	Per Cent	No.	Per Cent
1923	1,593	1,490	93.6	24	1.5	11	.7	40	2.5	28	1.7
1924	1,884	1,699	90.2	31	1.6	3	.2	108	5.7	43	2.3

Col. 1—Relay Failures (No Operation of Switch)

Under this heading are listed all cases where subsequent investigation has proved that conditions at the point in question were such as to permit correct relay operation but the relays failed to function. No case is listed as a relay failure if investigation proved the trouble to be due to a break, ground or other fault in the direct-current tripping circuit, or to mechanical defect in the switch or auxiliary apparatus external to the relay itself.

Col. 2—Total Relay Operations

This tabulation includes all cases of relay operation causing the opening of oil switches and is a summation of Cols. 3, 4 and 5. (Note—Cases of relay operation due to accidental shorting or closing of contacts are not included in this report).

Col. 3—Correct Relay Operations

Under this heading are listed all relay operations which have been proved to be correct under the conditions existing at the time. This tabulation includes many cases which were not entirely satisfactory from an operating standpoint, but where, owing to load, voltage and power-factor conditions, it was necessary to give the relays credit for correct operation, even though the results were not precisely as desired. There are also included in this table a number of cases in which unsatisfactory relay operation has occurred due to inadequate equipment. (See Col. 4) In all these cases, however, the relays themselves functioned correctly under the circumstances.

Col. 4—Incorrect Relay Operations Due to Relay

This tabulation includes all cases that have been proved by subsequent investigation and test to be due to faults, either mechanical or electrical, in the relays themselves. (Note—This classification does not include relay operations which were apparently faulty because of inadequate equipment or improper connections.)

Col. 4—Incorrect Relay Operations Due to External Causes

Under this classification are listed all cases of relay operation which investigation has shown to be the result of faults or improper connections in auxiliary apparatus external to the relays themselves.

Col. 5—Questionable Relay Operations

This table covers relay operations which it has been found impossible to classify under Col. 3 or 4. In most cases the operation has been unsatisfactory, but owing to the lack of evidence it was considered unfair to classify it as incorrect, particularly as a test made after the trouble showed the relays to be operating correctly so far as could be determined.

In Table IV is given the high tension relay operations for 1923 and 1924, and in Chart V is given the segregation of all high-tension troubles for the year 1924.

Of manual switching for 182,500 switching operations on the Pacific Gas and Electric Company system in a year, 23 caused trouble.

The greater portion of the high voltage troubles are phase-to-ground arcs caused by conditions fairly well known and to a considerable extent avoidable.

Insulation in any reasonable amount is not a positive insurance against direct strokes of lightning, severe storms or certain birds and no amount is proof against occasional man-made failures.

Stored Energy and Governing

The stored energy or fly-wheel effect of the rotating

1924

equipment on the network varies from 2350 ft-lb. per kv-a. in the larger hydro-electric units to 1195 ft-lb. per kv-a. in some of the smaller high speed units and typical steam turbo alternators. Typical steam turbo alternators have about 5500 ft-lb. per kv-a.

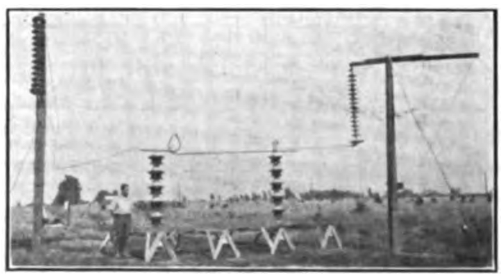

Fig. 19—Air-Switch Arrangement for Closing a Ground on the 220-Kv. Line

The effect of the rotating equipment connection as load is very difficult to determine but it was in the order of 20 per cent of the effect of the generating equipment on the network.

At any given point on the network only a certain portion of this energy is available in a case of switching

or trouble, varying for 3-phase, single-phase and phase-to-ground troubles in the same manner that the short circuit kv-a. varies as far as the distribution over the network is concerned, but the energy delivered is dependent on the rate of change of speed and also on the line and equipment characteristics.

Experience has demonstrated that for a load of 300,000 kw., a drop from 60 cycles to 59 cycles will drop the load about 3.5 per cent, while an increase of from

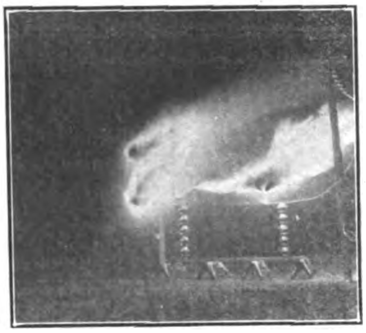

FIG. 20—PHOTOGRAPH OF A 220-KV. ARC DURING THE ARTIFICIAL FLASHOVER

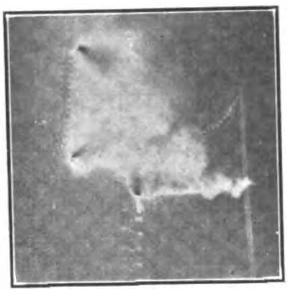

FIG. 21—SAME AS FIG. 20 FROM A DIFFERENT DIRECTION

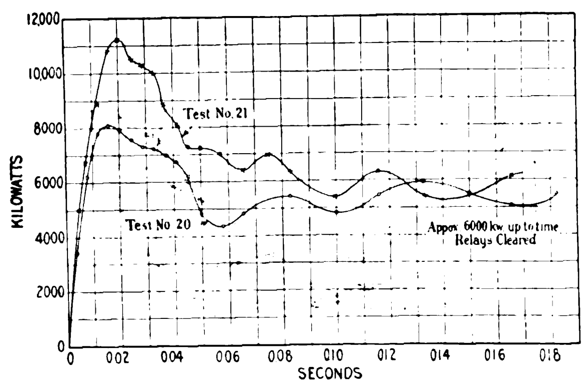

FIG. 22—RESIDUAL POWER IN ARTIFICIAL FLASHOVER

60 to 61 cycles increases the load about 4 per cent. This is due to the character of the load, some of which varies with the cube of the speed and some of which has no variation with speed. The actual percentages vary slightly therefrom with the season. The network is somewhat self-governing and the actual governing is done on one unit in a designated plant with all the remaining plants carrying block loads.

There are two methods of accomplishing this result:

1. Setting all governors on a flat speed characteristic to reject load at approximately ½ cycle above normal speed with a load limit set for a block load on all but the one governor used for regulation on turbines or a given nozzle opening on impulse wheels. Then as the speed varies too near the limit of the governing unit add to or reduce the block load to keep the governing unit in action.

2. Set all governors with a drooping speed characteristic and change the governor setting as load increases or decreases in the manner of the synchronizing motor on a steam turbine.

The Pacific Gas and Electric Company network uses the first on hydro-units and the second on steam, although various combinations have been used in the past.

On the network described above with the present system of relaying,[4] the speed does not drop enough during switching or trouble for the governors to act until after the switching is over. This is true for several reasons:

First, it is not possible to deliver sufficient kv-a. at any given point in the network to drop the speed fast enough to get governor action during the time it takes to clear trouble.

Second, governors, particularly on hydro units, have an operating time determined by the equipment controlled, *i. e.*, turbines, relief valves and penstocks, and this is of necessity a matter of several seconds.

All governors in general use today are used for holding speed and nothing else, and are, therefore, of necessity actuated only by speed. Particularly on hydroelectric units not having a means of by-passing the unit, the governors are definitely limited in action by penstock pressure rise, and are, therefore, a compromise between the cost of generators to stand overspeed and overvoltage and penstocks to stand over-pressure.

CHARGING CURRENT

Charging current on high-voltage lines plays an important part in system stability, and a considerable portion of the reported cases of instability are in fact improper operation. An example of this effect is shown in the tests where it was demonstrated that switching out a 220-kv. line at Vaca Substation and allowing it to trip on over voltage at Pit No. 1 was the most severe condition encountered as regards stability. This has also been checked in actual operation several times. It is due to the action of the line free at one end with nearly 30,000 kw. of corona loss and a leading current in the generator at Pit No. 1 Power-House. The voltage rises at Pit No. 1 Power-House in about 5 cycles and the line relays out in approximately over ¾

4. See *Electrical World*, November 22, 1924.

second under such conditions. In this connection must be considered the excitation characteristics of the generators and the manner and direction from which the charging current is supplied, *i. e.*, either from the system network and receiving-end condensers or from the generators themselves.

a. Corona. Corona load on long 220-kv. lines under certain switching conditions may be several thousand kilowatts and must be considered in stability problems.

b. Phase Balancing. On all 220-kv. switches so far installed and operated the difference in opening time of the three phases varies from 5 to 20 cycles and allows an interchange of power between phases as well as a damping action in the arc.

c. Impedance. Intimately connected with all network disturbances is the system impedance to the point in trouble. This, to be accurate, must include all the connected equipment with its proper characteristics, in most cases transient characteristics, because present-day operating practise developed by trial has demonstrated that the relay equipment must be able to separate equipment and lines in trouble in a time measured in seconds or parts of a second, or the damage done will permanently disable such line or equipment.

Very little is known about transient impedance values, particularly single-phase or phase-to-ground impedances. For most networks such data are not available nor has any practical method been developed for obtaining it.

The oscillographic wattmeter used on the flashover tests in this connection is believed to be an innovation in this respect.

All changes of load caused either by switching or grounds and short circuits are taken up in the network by a transient condition causing a change in speed followed by a readjusted steady state either at a new speed or at the same speed and new loads on one or more units.

The amount of speed change is dependent on the rate at which the stored energy can be absorbed at the point of trouble, and this in turn is dependent on the impedance which is varied by all of those things that affect the short-circuit problem, together with the character of the trouble, the excitation on the rotating equipment, charging current, corona and those things which go to make up the speed load characteristics of the network.

Conclusion

These tests represent the initial attempt to secure data of this character on a large network in actual operation. The manner of using such data and the results obtained therefrom are given in the companion paper by Evans and Wagner who were instrumental in furnishing both personnel and equipment for the tests thus far made.

CORRESPONDENCE

LEAKAGE REACTANCE

To the Editor:

I wish to take vigorous exception to Mr. Boyajian's statement in his closing discussion[1] on his paper, Resolution of Transformer Reactances, etc., that I "seem to be in agreement with the speaker on the main points of the paper." I had no such intention, and Mr. Boyajian has evidently misunderstood my discussion. In fact my position on this question of leakage reactance is entirely opposed to that set forth by Mr. Boyajian. Now it *seems* to me that he has fallen into error on account of the fact that the same "equivalent" circuit may be used to represent the behavior of a two-winding transformer, in which the exciting component of current is *not* neglected; or of a three-winding transformer, in which the exciting component of current is neglected. Since certain relations can be shown to exist in the latter case he argues that the same relations hold true in the former. This logic is entirely erroneous. As a matter of fact the conflicting views that have been expressed are occasioned by different conceptions of what leakage reactance really is. It seems to me that it would be very unfortunate if we were forced to use one value of leakage reactance when considering one component of current and a different value when considering another component; especially so, since the various components are, in reality, nothing but figments of the imagination. This, however, is Mr. Boyajian's conception for he says, "The burden of my paper was to show that the leakage reactance which a winding offers to exciting current is different from that which it offers to a load current, similar, etc."

Of the half dozen books which I have just consulted I find none that supports this view. The late Dr. Steinmetz, for example, in discussing the transformer assigns a definite leakage reactance to the primary and another definite leakage reactance to the secondary. There appears to be no question whatever of using one value of leakage reactance for an exciting component and a different one for a load component.[2] A good exposition of this point of view will be found in "Principles of Alternating Currents," R. R. Lawrence. The definition there given for the leakage inductance of winding No. 1 with respect to winding No. 2 is the difference between the self-inductance of winding No. 1 and the mutual inductance between windings Nos. 1 and 2 multiplied by the ratio of the turns. The leakage reactance of one winding is always given with respect to some other winding. It is not a function of one winding alone but of two windings. In this respect it is like mutual inductance. Of course, in a commercial transformer the self and mutual inductances are variable but their difference as described above is essentially constant except possibly under some extreme condition

1. A. I. E. E. Journal, October 1925, page 1140.
2. "Alternating Current Phenomena," C. P. Steinmetz.

of core saturation, inasmuch as the leakage-flux linkages of one winding with respect to the other must be due to flux that exists at least partly in air. Here I wish to emphasize most strongly that in general reactance is not a function of any particular current but depends solely upon the configuration of the electric circuit or circuits considered and the neighboring magnetic material and its condition. In general the condition of this magnetic material depends upon *all* of the currents and not upon any one or upon any component of any one.

So far as I am aware, any problem that depends upon variable reactances can be handled only by making suitable approximations. There is no doubt that the leakage reactance of one winding of a transformer with respect to another may be different with different core saturations. However, I have never seen any reliable data tending to show that these differences are significant. And even if they did exist, it would not mean that one value of leakage reactance should be used with one component and a different value with another component of current, as Mr. Boyajian implies.

With the foregoing conception of leakage reactance, the vector difference in potential between the primary and secondary potentials of a one-to-one two-winding transformer is the vector sum of the individual leakage-impedance drops in the primary and secondary windings. This use of vectors assumes that the currents are essentially sinusoidal. Ordinarily we assume that the two currents are equal, in which case the "equivalent" leakage reactance is the numerical sum of the individual leakage reactances. It is only when the exciting current is neglected, however, that this summation is allowable.

Now there is another point in this connection that Mr. Boyajian seems not to consider when he proposes his first test. It is that reactance can usefully be defined as the ratio of volts to amperes only when the wave form of the current is sinusoidal. For example, the third-harmonic component of drop in this test is probably much larger than the fundamental component. The test is therefore valueless without the wave form of exciting current, and even if this is known the accuracy is rather poor and the computation rather cumbersome. This same comment in regard to wave form of current applies to Mr. Boyajian's test No. 5. Prof. Dahl mentions this and I am entirely in agreement with him. The small variation that Mr. Boyajian noticed might be due either to transformer unbalance, as Prof. Dahl suggests, or to an actual change in the leakage reactance of the windings due to the change in the saturation of the core as I have previously cited. If oscillographic measurements had been made some useful results might have been presented in regard to this point.

His test No. 2 will give correct results only if the resistance is negligibly small as compared with the leakage reactance at fundamental frequency.[3] The advantage of tests Nos. 1 and 2 is that they may be run at normal core saturation. On the other hand potential transformers must be used if the ratio of transformation is other than unity. This is a real disadvantage, inasmuch as their ratio must agree with that of the transformers being tested to within a few hundredths of one per cent in order that they may introduce a small error. The currents also contain large third-harmonic components.

The disadvantages of tests Nos. 3 and 4 are that auxiliary transformers must be used if the ratio of the transformer being tested is other than unity and that the core is run at low saturation, so that if the leakage is a function of the saturation, this factor is disregarded.

The disadvantages of the third-harmonic method are that three identical transformers are required, and that to be certain of the results oscillographic measurements are necessary. On the other hand, the core saturation is normal and no auxiliary transformers are necessary to correct for a ratio other than unity. On the whole it seems to offer the best method for determining the individual leakages.

Let me emphasize, even at the risk of repetition, that the leakage inductance of one winding with respect to another is determined solely by the configuration of the two windings with respect to each other and to the iron core and by the magnetic condition of the latter. This magnetic condition fundamentally depends upon all of the currents acting and upon nothing less.

Now, in regard to three-circuit transformers, I have shown that the reactances which may be used to represent the individual windings in the equivalent net-work that Mr. Boyajian proposes are *not* the leakage reactances of the windings. Equations **6**, **7**, and **8** in my discussion show clearly what their composition really is. For example, the reactance that should be assigned to winding No. 1 is the *leakage* of this winding with respect to winding No. 2 *plus* the differential *mutual* effect of winding No. 3 upon windings Nos. 2 and 1 respectively.

W. V. LYONS

RADIO SETS ON FARMS

The farmers of the United States as a class have become radio enthusiasts and today have more than twice as many radio receiving sets as they did two years ago. In 1923 there were 145,000 receiving sets on farms throughout the country, while at the close of 1925 the number of these farmer sets had risen to 553,000.

Farmers have discovered that in order to get weather and market reports as well as the entertainment they desire they must have "good distance sets," and dealers selling radios to the farmers report that sets worth from $125 to $400 are much easier to sell than sets costing under $100. Also today 24 agricultural colleges in the United States maintain radio broadcasting stations and are paying a great deal of attention to the programs they put on the air.

3. Except when the ratio of resistance to leakage inductance is the same for the two windings.

Starting Characteristics and Control of Polyphase Squirrel-Cage Induction Motors

BY HORACE M. NORMAN[1]

Associate, A. I. E. E.

Synopsis.—*In the application of squirrel-cage induction motors to such severe service as frequent start and stop or frequent plugging operation, it is desirable to know how much loss the motor will be required to dissipate. Plugging being understood as changing the motor from any speed in one direction to any speed in the opposite direction, by reversing the rotation of the field only.*

The subject of starting loss is also of interest from the control standpoint; such as the application of auto-transformers for starting purposes; or where an external resistance is inserted in the primary as is done in the control of elevator motors.

Consideration is given to the part that the primary and secondary resistance and the total reactance play in the determination and the manipulation of the starting losses; and, as it is true that in many applications the time spent in accelerating the rotor from rest is useless from the production standpoint, consideration is given to the value of secondary resistance that will give minimum starting time for a given field strength. This involves a method for the determination of the time taken to attain a given speed in general.

There are many cases where a motor has already been designed and tested, and is about to be applied on a given job where the cycle of operation is known and includes either starting and stopping or plugging. In such an event, instead of working with the various test values to get the constants of the machine, it is much more convenient and accurate to work from such values as starting torque, maximum torque, slip at full load, locked current and primary resistance.

It will be shown how the proceeding short-cut method can for most cases be made more simple without sacrificing the accuracy of the result to any appreciable extent.

When a motor is plugged the problem is complicated by the difficulty that eddy currents flow in the rotor which give a slight increased effect to the torque at negative speeds. Although this paper does not show how to predetermine its amount, it does show how to handle the losses and the time of reversal, if the test speed-torque values are known or can be estimated from another machine.

* * * * *

When an induction motor is started up in series with an auto-transformer, the ratio of the loss in the motor and auto-transformer at any instant is a constant. The ratio of total loss over the entire starting period must have this same value. As this value can easily be calculated by considering any particular instant, such as the very start, it is obvious that the total loss in the auto-transformer is known when that of the primary of the motor is known. From this it can be seen that the two problems are reduced to that of the motor only.

It is true that in the vast majority of cases the r. m. s. value of starting current is very large compared to the magnetizing current and that sufficient accuracy can be obtained by neglecting the magnetizing current except in so far as it effects the torque.

Reducing the secondary circuit to terms of the primary and neglecting the magnetizing current, the iron, and the friction and windage losses it can be assumed that the secondary current is equal to the primary current. The ratio of the primary loss to the secondary loss during the starting period will then be as their respective resistances. Therefore:

$$\frac{\text{Total primary loss during starting period}}{\text{Total secondary loss during starting period}} = \frac{\text{Primary resistance}}{\text{Secondary resistance}} = \frac{r_1}{r_2}$$

The primary resistance is taken to be per leg of the winding, and the secondary resistance in terms of the primary can be found by

$$r_2 = \frac{T_{st}\, N}{7.04\, \phi\, I_L^2} \qquad (1)$$

where

T_{st} = starting torque
N = synchronous speed in rev. per min.
ϕ = number of phases
I_L = locked amperes per leg

To find the secondary loss during the starting period, it is only necessary to consider the field as at rest instead of the stator. In this case the stator would have to be considered as revolving backwards at synchronous speed and the rotor with it to correspond with the starting condition of the motor: then when the line switch is thrown in, a stationary field is set up which acts as a brake on the revolving rotor and tends to bring it to rest. The only difference between a mechanical and such an electrical brake is that the loss in one is in friction loss and the other in copper loss with perhaps a little iron loss. Since it does not matter to what degree a mechanical brake is applied the total loss is equal to the difference of the kinetic energy before and after, so in this case the loss is proportional to the square of the initial speed less the square of the final speed, the field being considered as stationary, and is also proportional to the total inertia resisting the change of speed. Assuming that there is no friction or hauling load during the starting period, then the rotor loss depends only on the above considerations from which the following formula can be evolved:

$$\text{Rotor loss (Joules)} = .00744\ (M\,I)\ N^2\ (s^2 - S^2) \qquad (2)$$

while changing from speed $N(1 - s)$ to speed $N(1 - S)$, inertia being the only resistance to motion. The total

1. Design Engineer, Westinghouse Electric & Manufacturing Co., East Pittsburgh, Pa.

Abridgment of paper to be presented at the Midwinter Convention of the A. I. E. E., New York, N. Y., February 8-11, 1926. Complete copies available to members on request.

inertia of the whole system being reduced to terms of the rotor and being equal to $(M\,I)$.

From this it can be seen that the loss during plugging is about four times as great as that for starting only.

Further, since the primary loss is to the secondary loss as r_1 is to r_2, and since the secondary loss is independent of the value of the secondary resistance, then it follows that the higher the secondary resistance the lower will be the primary loss during the starting or reversing period.

Assuming that the primary resistance varies as the turns squared, which is probable, then it is true that neither the primary nor secondary total joules loss during the starting period can be raised or lowered by changing the number of primary turns.

This is obvious when it is considered that the secondary resistance in terms of the primary varies as the primary turns squared; that is, as the primary resistance. The ratio of resistances is therefore a constant, and since the losses are of the same ratio and remembering that the secondary starting loss is independent of the secondary resistance, then the primary starting loss in joules is independent of the primary turns, assuming that the resistance varies as the turns squared.

It is also obvious that changing the primary voltage will not change these starting losses.

Any increase or decrease in reactance due to change of saturation or variation of turns does not change the total joules loss at start, it merely increases or decreases the time of start.

These arguments neglect friction and windage of the accelerated system which as a rule are of only secondary consideration.

It is, therefore, clear that the only way to decrease the starting loss of a squirrel-cage induction motor is to increase the secondary resistance. This, however, cannot be brought to the extreme because, if enough resistance be added, the accelerating torques will be reduced so much that the time taken to attain a given speed would be excessive and further the full-load slip would be too great, giving a very low running speed and poor efficiency.

The question then arises: What is the value of secondary resistance to best suit a given application?

There are two factors that enter into the determination of the answer. First, is the secondary resistance to be such that the losses in the motor during a complete cycle of operation are to be a minimum; and second, is it desirable to start up in the minimum time.

It is obvious that no mathematics can decide what compromise should be made between the two values of secondary resistance obtained from the two above considerations; but even though neither ideal is finally selected it is well to know what they are, so that the secondary resistance can be made some intermediate value.

To find the total losses during a complete cycle of operation, it is only necessary to multiply the running losses by their duration in seconds and add the starting or plugging loss in joules. This gives the total joules loss over a complete cycle of operation and if divided by the total time for the complete cycle, it gives the average watts loss for continuous operation.

The value of secondary resistance to give minimum average loss for continuous operation will naturally depend on the time and variation of the load and the number of stops and starts or reversals.

Assuming that the torque T for any slip s is given by

$$T = \frac{7.04\, E^2\, r_2\, \phi\, s}{N\left[r_2^2\left(\frac{E}{E_g}\right)^2 + 2\, r_1\, r_2\, s + (r_1^2 + x^2)\left(\frac{E}{E_g}\right) s^2\right]} \qquad (3)$$

then the time taken to start from rest and reach a speed corresponding to a slip of S is given by

$$\text{Time (seconds)} = .01487\,\frac{(M\,I)\,N}{E^2\,\phi}\left[r_2\left(\frac{E}{E_g}\right)^2 \log_e\left(\frac{1}{S}\right) + 2\, r_1\,(1-s) + \left(\frac{E}{E_g}\right)\frac{(r_1^2 + X^2)(1-S^2)}{2\, r_2}\right] \qquad (4)$$

Where

$(M\,I)$ = moment of inertia of the whole system transferred to and including the rotor (lb-ft.).
N = synchronous speed (rev. per min.)
E = Primary volts per leg
E_g = $E - X_1 I_m$
$X_1 I_m$ = no-load reactance drop in primary
ϕ = number of phases
r_1 = primary resistance per leg (add external primary resistance if any)
r_2 = secondary resistance per leg in turns of primary
X = total reactance (add external primary reactance if any)
S = normal or final slip

Use .0149 for constant

Assuming that all the constants of the motor are fixed with the exception of the secondary resistance, then the value of secondary resistance to give minimum time to attain a given speed can be derived from the preceding equation and will be as follows:

$$r_2 = \sqrt{\frac{(X^2 + r_1^2)(1 - S^2)}{4.6\left(\frac{E}{E_g}\right)\log_{10}\left(\frac{1}{S}\right)}} \qquad (5)$$

This formula gives the value of r_2 which would speed the motor from rest to $N\,(1 - S)$ revolutions per minute in the least time.

Oscillograph records were taken of a squirrel-cage motor when starting up and when plugged in order to check the assumption that the dry bearings at start cause a delay which is small compared with the total time of start; they were also taken with a view to checking the time to establish the field.

Fig. 1A and B show the current in the primary building up when the motor is started and plugged. It can be seen from A that the current is normal after

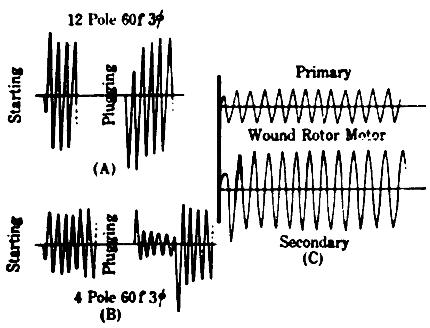

FIG. 1

about two cycles when the motor is started from rest and after four cycles when plugged. From B it can be seen that for start the current has about 90 per cent of its full value for about four cycles, and is then normal; when plugged there is some irregularity but after seven cycles the current is stable. This irregularity is probably due to one of the poles of the switch making bad

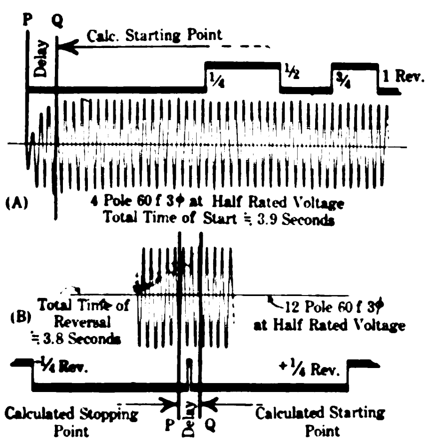

FIG. 2—(A) FOUR-POLE, 60-CYCLE, AT HALF RATED VOLTAGE, TOTAL TIME OF START = 3.9 SEC. (B) TWELVE-POLE, 60-CYCLE, AT HALF-RATED VOLTAGE, TOTAL TIME OF REVERSAL = 3.8 SEC.

contact. Later tests with a wound rotor showed that one of the contacts was poor as the primary current in this particular phase did not start till about one-tenth of a second after the secondary current had started up. This indicates that a faulty switch can cause excess loss in the motor because as soon as two poles make contact the motor will draw single-phase current which causes a loss in the stator and rotor but gives zero torque. It is only when the third pole makes contact that the motor starts up.

Fig. 1C shows the primary and secondary current of a wound rotor motor when started from rest. It can be seen that the secondary current builds up inside of two cycles.

From these tests it can be seen that it is not unreasonable to neglect the time taken to establish the field and the secondary current.

Fig. 2A shows the primary current waves of a squirrel-cage motor when starting up; and above it a line which is displaced after the rotor turns one quarter of a revolution and remains so for the next quarter revolution, etc. This line is obtained by mounting two contact strips diametrically opposite to each other on a paper pulley, each covering one quarter of the circumference of the pulley.

The pulley is mounted on the motor shaft so that every time a contact piece passes a stationary carbon brush a current is established which actuates the oscillograph. Working back from slips of 10 per cent, 50 per cent and 75 per cent to get the moment of inertia

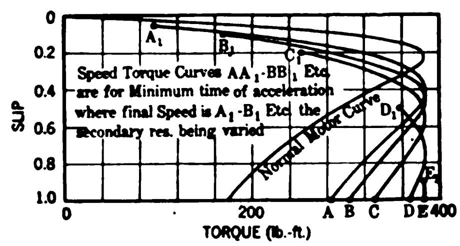

FIG. 3—SPEED TORQUE CURVES

A A-B B etc., are for min. time of accelerations where final speed is *A*, *B* etc., the final secondary resistance being varied

of the rotor and pulley and then using the result to get the instant of start, assuming there is no delay, the point *Q* is reached. Since the switch was thrown in at the instant *P* then the difference represents the delay. Fig. 2B represents the same thing when the motor is plugged. The delay in this case is for the excess friction when the rotor is changing direction of rotation. Both these delays are very small compared with the total time of start or plugging.

The usual value of friction and windage for a motor is such that it lowers the efficiency by only a few per cent so that it has the effect of reducing the torque exerted by the field on the rotor by only a few per cent at full load. For greater values of slip this reduction is less while the field torque is greater, which shows that it is justifiable to neglect it during the accelerating period, which has been done in the previous formulas.

Fig. 3 shows a series of curves each having the same maximum torque value, but which are for different values of secondary resistance. The various starting torques are obtained by using the value of secondary resistance obtained by formula (5) when the slips corresponding to A_1 B_1 etc., are used. These curves then give an idea of what shape the speed torque curve should have for the minimum time of acceleration to a

given speed (assuming that the only resistance to motion is in the form of inertia).

It should be noted that an erroneous conception is often held that the time of acceleration varies inversely as the average torque.

This would lead to the conclusion that a single-phase motor would start up since it has a definite average torque. The fact is that the time for any constant value of torque varies inversely as this torque, and this can be applied with reasonable accuracy for small changes in slip, but for the total accelerating period, it should be noted that the time of acceleration varies as the average of the inverse of the torque. This average being obtained by taking the inverse of the torques for equal increments of speed. From this it can be seen that the time can be abnormal if the torque for any speed whatever approaches zero and would be infinite if it did drop to zero, which means that the motor would never speed up beyond this point.

It is sometimes assumed that if the value of locked

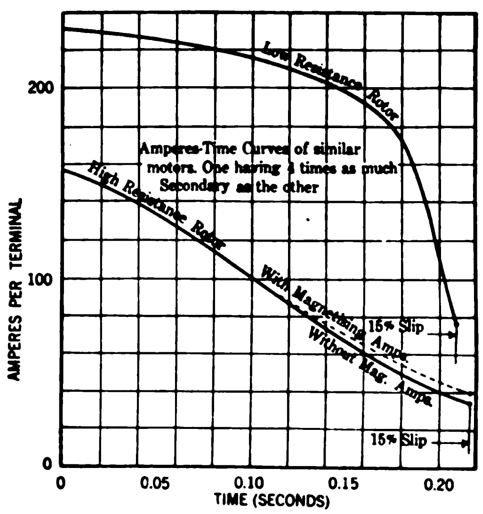

FIG. 4—AMPERE-TIME CURVES OF SIMILAR MOTORS

One having four times as much secondary resistance as the other

amperes is used for zero time and full-load amperes for the end of the accelerating period, then the current curve could be assumed to be a straight line joining these two points. This is not necessarily true, but happens that for some high resistance rotor motors it is nearly so. However, it is far from true of the average motor where the starting current tends to hang on, and in Fig. 4 is shown to be as high as 93 per cent of locked value after half the starting time is passed. This is the upper curve for the low resistance rotor. The lower curve is for a rotor with four times as much resistance, and it can be seen that the current falls off nearly as a straight line.

The torque curve for this latter motor would have nearly maximum torque at start.

It will be noted from these two curves how much the starting current is reduced for the high resistance rotor compared with the normal rotor, and also that the average current is still a lower ratio. The root mean square value of the two curves should have a ratio of nearly two because the time of start for each case is practically the same. The r. m. s. value of each current curve when multiplied by the time of start should have a ratio of exactly two, which, when squared and multiplied by the ratio of resistances gives unity; showing that the rotor loss is the same in either case as previously shown.

Since the stator winding is the same for either case, and noting that there is little difference in the time of start, it can readily be seen that the stator loss is much lower for the high resistance rotor than for the normal rotor.

TIME OF ACCELERATION USING TEST VALUES OF TORQUES

Taking the case of a normal resistance rotor motor when the duty cycle is known, it is true that in the majority of cases the motor which is finally selected has already been built and tested.

In such a case it is quicker to use these tested torques, than if a complete calculation were made of the machine.

The values required to find the time of acceleration from rest to a given speed are the slip at load torque equal to the starting torque, the maximum and starting torques, synchronous speed and moment of inertia of the rotor if starting light, and if loaded then the equivalent moment of inertia of the whole system, reduced to terms of the rotor.

Let

Maximum torque	$= T_m$
Starting torque	$= T_{st}$
Slip at load torque equal to T_{st}	$= s_1$
Synchronous speed	$= N$
Moment of Inertia (total)	$= (M\,I)$

$$T = \frac{a\,s}{b + c\,s + s^2} \qquad (4)$$

[Refer to formula (3)] where a, b and c are constants.

(a) $a = T_{st}\,(b + c + 1)$

(b) $b = s_1$

(c) $c = \dfrac{T_{st}\,(1 + s_1) - 2\sqrt{s_1}\,T_m}{T_m - T_{st}}$

From (a) (b) (c) the values of a, b and c can be found and can be substituted in a corresponding formula to (4), as follows:

Time of acceleration (sec.)

$$= \frac{\pi\,(MI)\,N}{30\,a}\left[2.3\,b\log_{10}\left(\frac{1}{S}\right) + c(1-S) + \frac{1-S^2}{2}\right] \qquad (6)$$

from rest to slip of S.

When the speed reaches 90 per cent to 95 per cent of synchronous speed, it can be assumed that it is near enough to be counted up to speed; then if 90 per cent is taken the log to the base ten becomes unity and for 95 per cent it becomes 1.301. It makes only a slight

difference in the time of start, whichever of the above final speeds is chosen.

Approximate Method Using only Maximum and Starting Torques

The preceding method can be simplified by assuming that the torque curve has a formula:

$$T = \frac{a\,s}{b + s^2} \qquad (\mathbf{8})$$

It should be noted that the value of a and b will be different in this formula than in formula (**6**) so that the part c plays is not entirely neglected.

Using only the maximum and starting torques, the

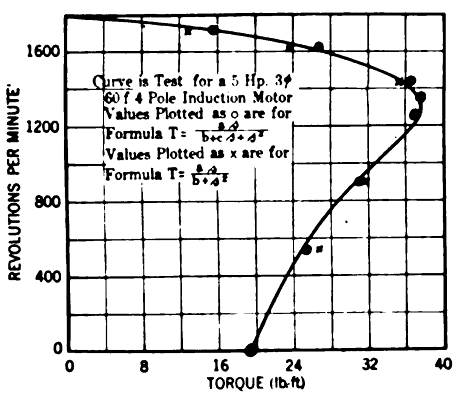

Fig. 5—Test Curve for 5-h. p., Three-Phase, 60-Cycle, Four-Pole, Induction Motor

Values plotted as O are for formula

$$T = \frac{a\,S}{b - c\,S - S^2}$$

Values plotted as X are for formula

$$T = \frac{a\,S}{b - S^2}$$

value of a and b for this formula are found in the following:

$a \;= 2\,S_m\,T_m$ or $= T_{st}\,(1 + b)$

$b \;= S_m^{\,2}$

where

$$S_m = \left(\frac{T_m}{T_{st}}\right) - \sqrt{\left(\frac{T_m}{T_{st}}\right)^2 - 1} = \text{Slip at maxi-}$$

mum torque as given by formula (**8**)

The curve plotted by using these values of a and b will have the same maximum and starting torque as test curve and will follow the test curve very closely.

The time equation then becomes:

$$\text{Time (seconds)} = \frac{\pi}{30} \times \frac{(M\,I)\,N}{a}$$

$$\left[\,2.3\,b\,\log_{10}\left(\frac{1}{S}\right) + \frac{1 - S^2}{2}\,\right] \qquad (\mathbf{9})$$

Fig. 5 shows a test speed torque curve and the calculated values for formula (**6**) plotted as (o) and those for formula (**8**) plotted as (x).

Speed Torque Equation for High-Resistance Rotor Motors

The two previous methods cannot be used for finding the equation of the speed torque curve of a motor which has approximately maximum torque at start. The following method should be employed: Find the ratio of torque to slip for a point infinitely close to the point torque = o, slip = o, by drawing a tangent to the curve at this point. Let this value be tangent θ.

Take the slip for some load torque, preferably of two-thirds the value of the starting torque. Let this slip be S_1 and the torque T_1. Let the starting torque $= T_{st}$

Then

$$a \;= b \tan\theta$$

$$b = \frac{1}{\dfrac{1}{S_1} - \dfrac{(T_{st} - T_1)\tan\theta}{(1 - S_1)\,T_{st}\,T_1}}$$

$$b = \frac{1}{\dfrac{1}{S_1} - \dfrac{\tan\theta}{2\,(1 - S_1)\,T_{st}}} \quad \text{if } T_1 = \frac{2}{3}\,T_{st} \qquad (\mathbf{10})$$

$$c = \frac{a}{T_{st}} - b - 1$$

and

$$\text{Torque} = T = \frac{a\,s}{b + c\,s + s^2}$$

Fig. 6 shows the test speed-torque curve in full,

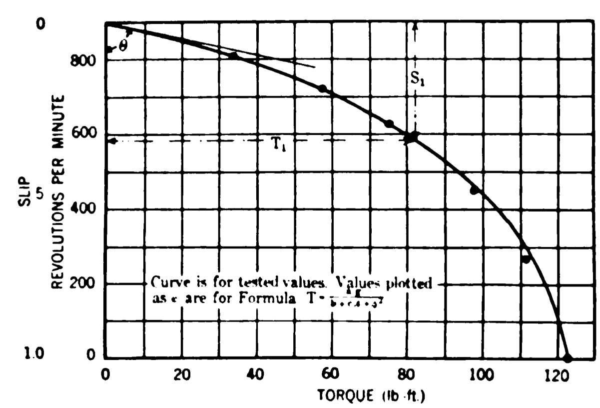

Fig. 6—Curve for Tested Values

Values plotted as O are for formula

$$T = \frac{a\,S}{b - c\,S - S^2}$$

and points calculated by this method plotted as ($\odot$).

Plugging Service

When a motor is plugged there are eddy currents in the rotor which are very pronounced at negative speeds. These eddy currents cause an increase in the rotor loss over what it would be if measures were taken to prevent eddy currents. This increase in the rotor loss makes the torque larger and since the eddy currents increase as the

slip increases it follows that the torques are affected more at negative speeds than at positive speeds. The increase in torque can be considerable and makes quite a difference in time of deceleration, and also in the joules loss in the primary.

When it is stated that there are eddy currents in the rotor it is meant that there are additional currents in the rotor bars besides a uniformly distributed current. These additional currents add in some places and subtract in others from the uniformly distributed current, and have the resultant effect of an uneven distribution.

Since the rotor copper loss is proportional to the average of the density squared of the current, then it can be shown that this loss is least when the density is uniform over the rotor bar. The loss must, therefore, be greater when the distribution is uneven, and this condition can be duplicated by a higher resistance rotor having no eddy currents.

The uneven distribution of current in the rotor bar is caused by variation of leakage flux linkages for different sections of the rotor bars, and is therefore more and more pronounced the higher the rotor frequency.

It is true that near standstill there is not a great deal of excess torque over what would be expected so that the equivalent secondary resistance can be assumed to be constant between rest and synchronous speed.

Since the derivation of formula (**2**) shows the secondary loss to be independent of the value of secondary resistance during acceleration or retardation, then it follows that it will be independent of a varying value of secondary resistance. But even though the primary resistance is constant the primary loss during this period depends on the variation of the secondary resistance.

For a high-resistance rotor motor, the major loss is in the secondary copper so that any variation in the primary loss as found by formula (**2**) when multiplied by the ratio of resistances can be neglected. Besides this latter consideration, it should be noted that a high resistance rotor will have less eddy currents than a low resistance rotor.

Therefore, when a high-resistance rotor motor is plugged the total loss during the total plugging time can be found by the following:

Joules loss in stator and rotor

$$= 0.00744 \frac{r_1 + r_2}{r_2} (M\ I)\ N^2 (4 - S^2) \qquad (\mathbf{11})$$

For high resistance rotor motors only and when motor is plugged.

When a low resistance rotor motor is plugged the primary loss is much less than the above formula would assume. The main difference being while the rotor is decelerating. The primary loss in joules during this time can be approximately found by assuming that the current is of constant value and equal to the current at the instant of plugging. This is very nearly true of a low resistance rotor motor but not so of a high resistance rotor motor in which case this current may be 30 per cent greater than the locked amperes.

The joules loss can be found by the following formula.

Joules loss in stator and rotor

$$= 0.00744 (MI) N^2 \left[\frac{r_1}{r_2} (1 - S^2) + 4 - S^2 \right] + \phi r_1 I_p^2 t_p \quad (\mathbf{12})$$

For low resistance rotor motors only and when rotor is plugged.

Where

I_p = amperes per leg of the winding at the instant of plugging.

and

t_p = time for rotor to come to rest.

The value of t_p can be approximately found as follows:

$$t_p \text{ (seconds)} = \frac{\pi}{60} (M\ I)\ N \frac{T_{plug} + T_{st}}{T_{plug} \times T_{st}}$$

where

T_{plug} = the torque at the instant of plugging.

Equivalent Moment of Inertia (In Terms of the Rotor)

It will be noticed that every time and loss formula includes the term ($M\ I$) which is the total inertia of the whole system reduced to terms of the rotor.

As this figure is the result of multiplying every small mass by its velocity squared and comparing it with that of the rotor, it can be seen that there are many cases where the rotor, due to its high speed, plays the major part in holding back the whole system from instantly coming up to speed.

The moment of inertia of the rotor should be known then if the preceding formulas are expected to give the correct losses and times.

The following method lends itself to great accuracy, due to the fact that the only measurement necessary is time. The other dimensions used are the journal sizes, which are very accurately ground to size, and are both of equal size and known beforehand.

The equipment is two rails accurately machined to a very large radius. These are placed parallel to each other and the rotor is placed on them so that each journal rides on a rail.

As the rails are circular the rotor naturally will swing back and forth with a harmonic motion.

Fig. 7 shows the scheme suggested.

Let

R = radius of gyration of the rotor (ft.)

P = period of rotor swing (sec.)

r = radius of rotor bearings (ft.)

l = radius of the circular rails (ft.)

g = gravity

Then

$$\text{Radius of gyration} = R = r \sqrt{\frac{P^2\, g\, (l - r)}{4\, \pi^2\, l^2} - 1}$$

When this formula is used it will be noticed that the

first term under the radical is very large compared with the second term, provided that l is very large. The accuracy with which R is obtained then approaches that of the period P.

The radius of the rails l should be made very large so that the period becomes very large and tends to eliminate windage, and also so that for a given amplitude of swing the angle of the rails will be small and so prevent slipping of the journals on the rails.

The accuracy of R is unaffected by the fact that the rotor might be placed on the rails slightly skewed so that when at rest the bearings would not be at the lowest point of the rails.

External Moving Parts

In transferring the inertia of external moving parts to terms of the rotor, the following rules are sufficient for most cases.

1. All parts that have only linear motion should be transferred according to the following law.

$$(M\ I) \text{ equivalent } = \frac{W}{g}\left(\frac{30\ V}{\pi\ (\text{r. p. m.})}\right)^2$$

Where

$(M\ I)$ equivalent = moment of inertia when transferred to the rotor.

W = external weight in lb.

V = velocity of W in ft. per sec.

g = gravity

(r. p. m.) = revolutions per min. of rotor

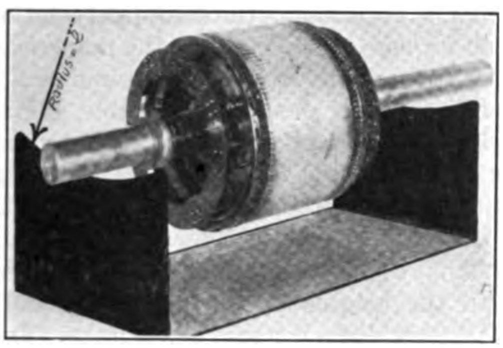

Fig. 7—Curve for Tested Valves

Valves plotted O are for formula

$$T = \frac{a\ S}{b - c\ S - S}$$

2. All parts that have a rotary motion only should be transferred by having their moment of inertia multiplied by the square of the ratio of their speed compared with the speed of the rotor.

All previous formulas pertaining to loss or time have been evolved with the assumption that the only resistance to motion is inertia. This is approximately so in a great many cases, but if any particular application should have a large friction or hauling load to overcome then these formula cannot be used. Any friction or hauling load should be applied as a reduction in torque and not as some supposedly equivalent inertia.

If the complete current torque curve be not available then it can be built up from the speed-torque curve by the following:

$$I_1 = I_2 = \sqrt{\frac{N\ s\ T}{7.04\ \phi\ r_2}} = \sqrt{s\ T} \times \text{constant}$$

where s and T are the values of slip and torque corresponding to the current.

Conclusion

For all cases worked out the primary loss has been found so that if some type of control be in the circuit, the loss can be found for it during a complete cycle of operation. The proper size controller can then be applied which will not have an excessive factor of safety.

When a motor is to be used for either starting and stopping or reversing service, the total losses of the motor during a complete cycle can be found by the preceding formulas. Knowing from test the amount of loss that the motor can dissipate for a definite rise of temperature, and knowing the loss it will be required to dissipate, the temperature rise of the motor can be predicted.

This estimated rise indicates whether or not the proper size motor has been selected.

THE DISTANCE RANGE OF RADIO TELEPHONE BROADCASTING STATIONS

As is well known, the conditions affecting radio transmission are too complex to permit a simple analysis. A direct method of studying such conditions and their variations is the analysis of a large number of similar observations taken by an organized group of observers of receiving conditions. The Bureau of Standards has made such an investigation, and part of the results are described in a paper just issued, Technologic Paper No. 297, A Statistical Study of Conditions Affecting the Distance Range of Radio Telephone Broadcasting Stations, by C. M. Jansky, Jr. This paper describes one year's work on the investigation of conditions affecting distance range of broadcasting stations by the Bureau of Standards with the aid of about 100 voluntary observers. The observations were made for a year in the period 1922-23 on transmitting station KDKA of the Westinghouse Electric & Manufacturing Co., East Pittsburgh, Pa. The observers were scattered over all distances up to 400 miles from the transmitting station. The data obtained were analyzed on automatic machines. The paper gives charts showing (1) variation of strength of atmospherics, (2) variation of fading, (3) relative magnitude of obstacles to reception, (4) variation of interference from receiving sets, (5) relative magnitude of obstacles to reception grouped in bimonthly periods, and (6) mean reliability of reception as a function of distance. A copy of this paper may be obtained for 5 cents from the Superintendent of Documents, Government Printing Office, Washington, D. C.

The Cross-Field Theory of Alternating-Current Machines

BY H. R. WEST[1]

Associate, A. I. E. E.

Synopsis.—*It is the purpose of this paper to show how analysis by the cross-field theory may be used to obtain accurate, purely numerical methods of calculating performance characteristics of alternating-current machines. Methods of calculation are derived and sample calculations are given for the single-phase induction motor and the repulsion motor.*

ALTERNATING-current machines may be analyzed according to either the revolving-field or the cross-field theory. Each of these theories has its own individual merits, depending more or less on the type of machine under consideration. Some phenomena are more easily understood by a study following the revolving-field theory, and other phenomena are made more clear by use of the cross-field theory.

For routine calculation of performance characteristics of alternating-current machines, many graphical and analytical methods have been developed. These different methods also have their own individual merits and the choice of a method of calculation should depend partly on what is most desired; *e. g.*, speed, accuracy, or aid to visualization.

Therefore, we may say that, in general, neither the revolving-field nor the cross-field method of analysis, and no one method of calculation, graphical or analytical, should be used exclusively. Although this paper deals only with a general analytical method of studying some types of a-c. machines using the cross-field theory, it is not by any means intended as a plea for the exclusive use of this general method, for it is recognized that whatever usefulness it may have will be found in rather limited fields.

In the following, the attempt is made to show how a general method of analysis, following the cross-field theory, may be applied to alternating-current motors to obtain simple and accurate, purely numerical methods for routine calculations of performance characteristics. The fundamental principles of the analysis of motors by the cross-field method are, of course, very well known. The general method given below is fundamentally the same as that outlined by Steinmetz in his "Theory and Calculation of Electrical Apparatus," but differs from it in the treatment of the leakage reactance, and in the arrangement of the results.

Briefly stated, the general method as applied to a motor is as follows: Kirchoff's voltage equations are set up for the different circuits of the motor and are solved to obtain equations for the currents in each of the circuits in terms of the applied voltage, the design constants of the motor and the speed. From these equations, other equations for the fluxes linking or cut by the rotor conductors are obtained. The torque corresponding to any one of the rotor circuits is obtained by multiplying the in-phase components of the current and the fluxes cut by the conductors of that circuit. Adding the components of torque corresponding to each of the rotor circuits, we obtain an expression for the total torque developed, which, multiplied by the speed, gives the power generated. Subtracting from this the friction losses gives the power output. The power input is, of course, given by the product of the applied voltage and the in-phase component of the line current.

In this paper, the angle of hysteretic lag between flux and m. m. f. is neglected in the analytical solutions, and correction for core loss is made in the numerical calculations by treating the core loss the same as if it were a friction loss. If it should be desirable, the angle of hysteretic lag can be taken into account by using the complex quantity $Z_m = R_m + j\,X_m$ for the magnetizing impedance in place of the pure reactance $j\,X_m$ which is used in the equations in the following part of this paper. This would complicate matters slightly by adding to the lengths of the equations, and would yield but a very slight increase in accuracy. In almost all cases, the slight increase in accuracy would not justify the extra labor and chances for numerical errors.

Sine wave distributions of m. m. f., and uniform air-gap permeance are assumed in all cases.

The details and application of the method can best be shown by means of examples, as follows:

THE SINGLE-PHASE INDUCTION MOTOR

According to the cross-field theory, the components of the main flux of the motor and the rotor currents are considered separately in two axes at right angles to each other. The axis of the stator winding may be called the transformer axis, and the axis at right angles to it the field axis. A squirrel cage is considered as equivalent to a commutated winding with brushes bearing on the commutator short circuited on themselves in the transformer and field axes. The motor can then be represented diagrammatically as in Fig. 1.

1. Electrical Engineer, General Electric Co., Pittsfield, Mass.

To be presented at the Midwinter Convention of the A. I. E. E., New York, N. Y., February 8-11, 1926.

The following symbols will apply:

E = applied voltage
I_1 = line current
I_{1a} = power component of line current
I_{1b} = reactive component of line current
I_{2t} = rotor current in the transformer axis
I_{2f} = rotor current in the field axis
r_1 = resistance of the stator winding
r_2 = resistance of each of the rotor circuits
X_m = mutual inductive reactance of the stator and rotor windings
x_1 = leakage reactance of the stator winding
x_2 = leakage reactance of each of the rotor circuits
N = effective number of turns in each of the circuits
f = frequency of applied voltage
S = speed as a fraction of synchronism

The symbols for voltage and current all represent r. m. s. values of time vector quantities. The positive senses of the currents are indicated by the arrows in Fig. 2.

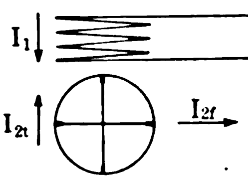

FIG. I

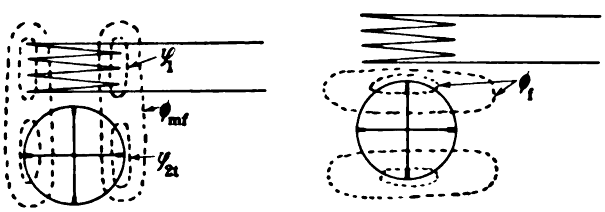
The motor flux is resolved into the following four components: (1) the "transformer" flux Φ_{mt} which is the flux that is mutual to the stator winding and the rotor circuit in the transformer axis; (2) the "field flux Φ_f which is the flux produced by the m. m. f. of the current I_{2f} in the field axis of the rotor; (3) the leakage flux φ_1 of the primary, and (4) the leakage flux φ_{2t} of the rotor circuit in the transformer axis.



A B

FIG. 2—FLUX COMPONENT IN SINGLE-PHASE INDUCTION MOTOR

(a) In transformer axis
(b) In field axis

In terms of the currents and the motor reactances, the equations for the above flux components are:

$$\Phi_{mt} = \frac{X_m (I_1 - I_{2t})}{2 \pi f N} \tag{1}$$

$$\Phi_f = \frac{(X_m + x_2) I_{2f}}{2 \pi f N} \tag{2}$$

$$\varphi_1 = \frac{x_1 I_1}{2 \pi f N} \tag{3}$$

$$\varphi_{2t} = \frac{x_2 I_{2t}}{2 \pi f N} \tag{4}$$

Voltage applied to the stator terminals must overcome the resistance drop and the mutual and leakage reactance drops due to alternation of Φ_{mt} and φ_1. The equation is

$$E = r_1 I_1 + j x_1 I_1 + j X_m (I_1 - I_{2t}) \tag{5}$$

In the transformer axis of the rotor, the sum of the voltages induced by transformer action of Φ_{mt} and φ_{2t}, and by rotation through the flux φ_f plus the resistance drop $r_2 I_{2t}$ must equal zero. The equation is, for counter clockwise rotation of the rotor,

$$0 = -j X_m (I_1 - I_{2t}) - S (X_m + x_2) I_{2f} + r_2 I_{2t} + j x_2 I_{2t} \tag{6}$$

Similarly for the field axis of the rotor,

$$0 = j (X_m + x_2) I_{2f} - S X_m (I_1 - I_{2t}) + S x_2 I_{2t} + r_2 I_{2f} \tag{7}$$

Solving these three voltage equations for I_1, I_{2t}, and I_{2f} we get,

$$I_1 = E \frac{[-r_2^2 + (1 - S^2)(X_m + x_2)^2 - j\, 2\, r_2 (X_m + x_2)]}{U_1' + j W_1'} \tag{8}$$

$$I_{2t} = E X_m \frac{(1 - S^2)(X_m + x_2) - j r_2}{U_1' + j W_1'} \tag{9}$$

$$I_{2f} = - \frac{S E X_m r_2}{U_1' + j W_1'} \tag{10}$$

Where

$$U_1' = - r_1 r_2^2 + 2 r_2 x_1 (X_m + x_2) + r_2 X_m (X_m + 2 x_2) + (1 - S^2) r_1 (X_m + x_2)^2 \tag{11}$$

$$W_1' = - r_2^2 x_1 - 2 r_1 r_2 (X_m + x_2) - r_2^2 X_m + (1 - S^2) [x_1 (X_m + x_2)^2 + x_2 X_m (X_m + x_2)] \tag{12}$$

Substituting the above values of I_1, I_{2t}, and I_{2f} in equations (1), (2) and (4), we get

$$\Phi_{mt} + \varphi_{2t} = \frac{- E X_m [r_2^2 + j r_2 (X_m + x_2)]}{2 \pi f N (U_1' + j W_1')} \tag{13}$$

and

$$\Phi_f = - \frac{S E X_m (X_m + x_2) r_2}{2 \pi f N (U_1' + j W_1')} \tag{14}$$

The torque developed by the motor consists of two components, one component T_1 due to the interaction of the current I_{2t} and the flux Φ_f, and another component T_2 due to the interaction of I_{2f} and the flux $\Phi_t = \Phi_{mt} - \varphi_{2t}$. These torque components in synchronous watts are equal to the products of the in-phase components of the currents and the fluxes with which they interact multiplied by $2 \pi f N$; that is, from equations (9) and (14).

$$T_1 = \frac{E^2 X_m^2 (X + x_2)^2 r_2 S (1 - S^2)}{U_1'^2 + W_1'^2} \tag{15}$$

and from equations (10) and (13)

$$T_2 = \frac{-E^2 X_m^2 r_2^3 S}{U_1^{1\,2} + W_1^{1\,2}} \tag{16}$$

and the total torque developed by the motor is

$$T = T_1 + T_2 = \frac{E^2 X_m^2 r_2 S\,[(1 - S^2)(X_m + x_2)^2 - r_2^2]}{U_1^{1\,2} + W_1^{1\,2}} \tag{17}$$

This equation shows that the torque developed by the motor is zero when

$$1 - S^2 = \frac{r_2^2}{(X_m + x_2)^2}$$

or the ideal no-load speed is

$$S_0 = \sqrt{1 - \frac{r_2^2}{(X_m + x_2)^2}} \tag{18}$$

Substituting the above value for the no-load speed in equation (7), we obtain for the no-load current,

$$I_0 = \frac{2\,E\,(X_m + x_2)}{2\,r_1(X_m + x_2) + \dfrac{r_2\,X_m^2}{X_m + x_2} + j\,X_m\,[X_m + 2\,(x_1 + x_2)]}$$

For all usual relative values of the design constants, this is very closely,

$$I_0 \simeq -j\,\frac{2\,E}{X_m}\left[\frac{X_m + x_2}{X_m + 2\,(x_1 + x_2)}\right]$$

$$\simeq -j\,\frac{2\,E}{X_m}\left[1 - \frac{2\,x_1 + x_2}{X_m + 2\,(x_1 + x_2)}\right] \tag{19}$$

It is obvious that by means of this equation, the value of the magnetizing reactance X_m can be calculated with any desired degree of accuracy from the values of the short-circuit and no-load currents.

The performance characteristics of a motor of given design constants can be calculated completely by means of equations (8) and (17). The solution of these equations can be reduced to a simple matter of arithmetic by means of a suitable printed form, arranged for carrying out the calculations for a number of different speeds simultaneously. The use of very large numbers will be avoided and the calculations for motors of different sizes will be more nearly alike if the numerators and denominators are divided by $(X_m + x_2)^2$ and $(X_m + x_2)^4$ in equations (8) and (17) respectively. This gives

$$I_1 = \frac{M_1 + j\,N_1}{U_1 + j\,W_1} \tag{8'}$$

$$T = \frac{S\,F_8 + S\,(1 - S^2)\,F_9}{U_1^2 + W_1^2} \tag{17'}$$

Where

$M_1 = F_1 + (1 - S^2)\,F_2$
$N_1 = F_3$
$U_1 = F_4 + (1 - S^2)\,F_5$
$W_1 = F_6 + (1 - S^2)\,F_7$

The complete expressions for F_1 to F_9 inclusive are given in the following sample calculation.

Performance Calculation of Single-Phase Induction Motor

Motor design constants:

$E = 220$
$r_1 = 0.12$
$r_2 = 0.3$
$x_1 = 0.4$
$x_2 = 0.4$
$X_m = 15$

Core loss and friction = 600

$F_1 = -E\dfrac{r_2^2}{(X_m + x_2)^2} = -0.0835$

$F_2 = E = 220$

$F_3 = -2\,E\dfrac{r_2}{X_m + x_2} = -8.57$

$F_4 = r_2\left[\dfrac{x_2\,X_m - r_1\,r_2}{(X_m + x_2)^2} + \dfrac{X_m + 2\,x_1}{X_m + x_2}\right] = 0.315$

$F_5 = r_1 = 0.12$

$F_6 = -r_2\left[\dfrac{r_2\,(X_m + x_1)}{(X_m + x_2)^2} + \dfrac{2\,r_1}{X_m + x_2}\right] = -0.0105$

$F_7 = x_1 + x_2\dfrac{X_m}{X_m + x_2} = 0.789$

$F_8 = -E^2\,r_2^3\dfrac{X_m^2}{(X_m + x_2)^4} = -5.23$

$F_9 = E^2\,r_2\dfrac{X_m^2}{(X_m + x_2)^2} = 13{,}800.$

(31) Power output = S . (30)	−653	4460	10300	15300	14700
(32) Efficiency = (31)/(24)		0.808	0.812	0.725	0.532

It will be noted that all the steps are indicated in the above. It is obvious that if a printed calculation form arranged as the above is used, the calculation of the complete performance characteristics of the single-phase induction motor is made comparable to a simple problem of bookkeeping, and can be done by a person without any technical training.

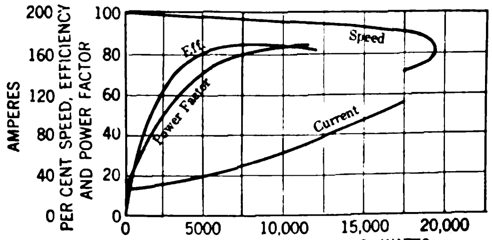

Fig. 3—Performance Characteristics of Single-Phase Induction Motor

The performance curves plotted from the above calculated values for current, torque, power factor, and efficiency are shown in Fig. 3.

As a further illustration, the method will be applied to the repulsion motor.

The Repulsion Motor

As usually built, the stator of a repulsion motor has a simple single-phase winding. This stator winding may be considered as made up of two windings, one which may be called the transformer winding and which is in inductive relation to the commutated winding, and

the other which may be called the field winding, which is at right angles to the axis of the commutated winding. According to the assumption of sine wave distributions of m. m. f., which is approximately realized in most cases, the transformer winding component will have $N \cos A$ effective turns, and the field winding component will have N sine A effective turns, where A is the angle in electrical degrees between the axis of the commutated winding as determined by the brush position and the transformer axis. The motor can be represented diagrammatically as in Fig. 4.

The same symbols that were used for the single-phase induction motor will apply for the repulsion motor and in addition we have,

I_3 = local short-circuit current in the coils short-circuited by the brushes.

r_3 = resistance of the local short circuits formed by the coils short-circuited by the brushes and the brush contacts.

The leakage reactance of the local short circuits is assumed the same as that of the rotor winding as a whole, viz., x_2.

We have, therefore, three circuits to consider in the repulsion motor, and three corresponding voltage equations. For the stator winding we have,

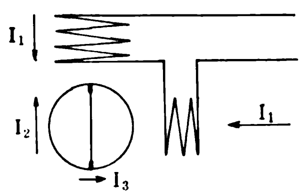

Fig. 4

$$E = j X_m (I_1 \cos^2 A - I_2 \cos A) + j X_m (I_1 \sin^2 A - I_3 \sin A) + (r_1 + j x_1) I_1 \qquad (20)$$

For the rotor winding proper,

$$O = - j X_m (I_1 \cos A - I_2) + (r_2 + j x_2) I_2 + S X_m I_1 \sin A - S (X_m + x_2) I_3 \qquad (21)$$

For the coils short circuited by the brushes,

$$O = - j X_m (I_1 \sin A - I_3) - S X_m (I_1 \cos A - I_2) + S x_2 I_2 + (r_3 + j x_2) I_3 \qquad (22)$$

Solving for I_1, I_2 and I_3, we get the equations,

$$I_1 = E \frac{[r_2 r_3 - (1 - S^2)(X_m + x_2)^2 + j (r_2 + r_3)(X_m + x_2)]}{U_2' + j W_2'} \qquad (23)$$

$$I_2 = E X_m \frac{[-S r_3 \sin A - (1 - S^2)(X_m + x_2) \cos A + j r_3 \cos A]}{U_2' + j W_2'} \qquad (24)$$

$$I_3 = E X_m \frac{[S r_2 \cos A - (1 - S^2)(X_m + x_2) \sin A + j r_2 \sin A]}{U_2' + j W_2'} \qquad (25)$$

Where

$$U_2 = - r_2 X_m^2 \cos^2 A - r_3 X_m^2 \sin^2 A - (r_2 + r_3)(x_1 + x_2) X_m - (r_2 + r_3) \; x_1 x_2 + r_1 r_2 r_3 - (1 - S^2) r_1 (X_m + x_2)^2$$

$$W_2' = r_1 (r_2 + r_3)(X_m + x_2) + r_2 r_3 (X_m + x_1) + S (r_3 - r_2) X_m^2 \sin A \cos A - (1 - S^2)(X_m + x_2) [X_m (x_1 + x_2) + x_1 x_2]$$

The components of the motor flux which react with the currents I_2 and I_3 to produce torque are the field flux Φ_f and the transformer flux Φ_t,

Where

$$\Phi_f = \frac{X_m I_1 \sin A - (X_m + x_2) I_3}{2 \pi f N} \qquad (26)$$

and

$$\Phi_t = \frac{X_m I_1 \cos A - (X_m + x_2) I_2}{2 \pi f N} \qquad (27)$$

The torque developed by the motor at any speed is, in synchronous watts,

$$T = 2 \pi f N [(I_2 \, . \, \Phi_f) - (I_3 \, . \, \Phi_t)]$$

where $(I_2 \, . \, \Phi_f)$ and $(I_3 \, . \, \Phi_t)$ represent the products of the in-phase components of I_2 and Φ_f, and I_3 and Φ_t, respectively. Substituting for the currents and fluxes their values from equations (**23**) to (**27**) and multiplying out, we get,

$$T = \frac{E^2 X_m^2}{U_2'^2 + W_2'^2} \left\{ \begin{array}{l} (r_3^2 - r_2^2)(X_m + x_2) \sin A \cos A \\ + (r_3 \sin^2 A + r_2 \cos^2 A) \\ [-S \; r_2 \; r_3 + S (1 - S^2)(X_m + x_2)^2] \end{array} \right\} \qquad (28)$$

The no-load speed is obtained by solving the cubic equation that is obtained by putting $T = 0$ in the above. An approximate solution is,

$$S_0 \simeq \sqrt[3]{1.5 + \frac{r_3}{X_m \left(\tan A + \frac{r_2}{r_3} \cot A\right)}}$$

This approximate equation is theoretically much more accurate than any calculated value of r_3 can be expected to be. Its chief value is to show how the no-load speed of a repulsion motor might be affected by changes in design.

Special simplified formulas for the current and torque at synchronous speed or at standstill can be obtained by putting $S = 1$ or $S = 0$ in equations (**23**) and (**28**). Slight approximations can then be made by which the equations are reduced to rather simple formulas which need not be given here.

The performance characteristics of the motor can be calculated completely from equations (**23**) and (**28**). For calculation purposes, it is advisable to divide the numerators and denominators of these equations by $(X_m + x_2)^2$ and $(X_m + x_2)^4$ as in the case of the single-phase induction motor. This gives,

$$I_1 = \frac{M_2 + j\,N_2}{U_2 + j\,W_2}$$

$$T = E^2\,\frac{G_9 + S\,G_{10} + (1 - S^2)\,G_{11}}{U_2^2 + W_2^2}$$

Where

$$M_2 = G_1 + (1 - S^2)\,G_2$$
$$N_2 = G_3$$
$$U_2 = G_4 + (1 - S^2)\,G_5$$
$$W_2 = G_6 + S\,G_7 + (1 - S^2)\,G_8$$

The complete expressions for G_1 to G_{11} inclusive are given in the following sample calculation.

PERFORMANCE CALCULATION OF REPULSION MOTOR

Motor design constants:

$r_1 = 1.1$
$r_2 = 3.5$
$r_3 = 100$
$x_1 = 2.8$
$x_2 = 2.8$
$X_m = 60$
$A = 15°$

Core loss and friction = 110 watts

$$G_1 = E\,\frac{r_2\,r_3}{(X_m + x_2)^2} = 19.5$$

$$G_2 = -\,E = -220$$

$$G_3 = E\,\frac{r_2 + r_3}{X_m + x_2} = 363$$

$$G_4 = -(r_3 \sin^2 A + r_2 \cos^2 A)\left(\frac{X_m}{X_m + x_2}\right)^2 - \left(\frac{r_2 + r_3}{X_m + x_2}\right)\left(x_1 + \frac{x_2\,X_m}{X_m + x_2}\right) + \frac{r_1\,r_2\,r_3}{(X_m + x_2)^2} = -17.98$$

$$G_5 = -\,r_1 = -\,1.1$$

$$G_6 = \frac{1}{X_m + x_2}\left(r_1\,r_2 + r_1\,r_3 + r_2\,r_3\,\frac{X_m + x_1}{X_m + x_2}\right) = 7.39$$

$$G_7 = (r_3 - r_2)\left(\frac{X_m}{X_m + x_2}\right)^2 \sin A \cos A = 22.0$$

$$G_8 = -\left(x_1 + \frac{x_2\,X_m}{X_m + x_2}\right) = -\,5.47$$

$$G_9 = +\,\frac{X_m^2\,(r_3^2 - r_2^2)\sin A \cos A}{(X_m + x_2)^3} = 36.3$$

$$G_{10} = -\,\frac{X_m^2\,r_2\,r_3}{(X_m + x_2)^4}\,(r_3 \sin^2 A + r_2 \cos^2 A) = -\,0.80$$

$$G_{11} = \left(\frac{X_m}{X_m\,x_2}\right)^2 (r_3 \sin^2 A + r_2 \cos^2 A) = 9.05$$

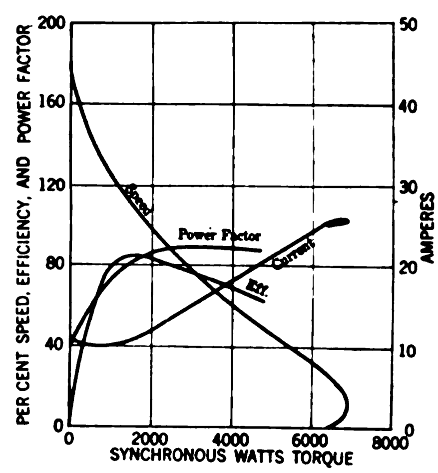

FIG. 5—PERFORMANCE CHARACTERISTICS OF REPULSION MOTOR.

The performance curves corresponding to the following calculated values are shown in Fig. 5.

It will be noted that this calculation form is, in general outline the same as that used for the single-phase induction motor, practically the only differences being in the expressions for the constants F_1, F_2, etc., and G_1, G_2, etc.

The single-phase induction motor and the repulsion motor have been chosen to illustrate the general method of analysis by the cross-field theory on account of their relative simplicity. The same general method might be applied to machines of more complicated types, such as those having four or more circuits to consider, but the method of procedure would be essentially the same, and the results would merely be somewhat more complicated. The analytical solution of such a motor by the same general method has been given in a previous paper. (TRANS. A. I. E. E., 1924, p. 1048.)

The Calculation of Magnetic Attraction
By the Aid of Magnetic Figures

BY TH. LEHMANN[1]
Non-member

Synopsis.—*The present paper treats of the following matters:*

1. Simplification of the physical formula for magnetic attraction

2. Definition of magnetic reluctance when the magnetic field is bounded by non-equipotential surfaces

3. Calculation of the virtual variation in magnetic reluctance due to any displacement of the limiting surfaces

4. Demonstration of the theorem that the magnetic attraction between two ferromagnetic bodies depends only upon their common magnetic fluxes ϕ *and upon the virtual gradient of its air-reluctances* R_o, *and that the formula*

$$F_l = \frac{\phi^2}{8\pi} \frac{\delta R_o}{\delta_l}$$

which gives the attraction along any given direction l *is as general and as exact as the formulas of physics*

5. Direct deduction of magnetic attraction from the lines of magnetic flux depicted by a magnetic figure without resorting to the components of the magnetic field.

The method used is developed by the application of the well-known principles of the potential energy function to the magnetic flux in the air-gap. Paths for the magnetic flux are established across the air-gap between the two ferromagnetic surfaces bounding the air-gap, by decomposing the magnetic flux into elemental tubes of magnetic force, the envelopes of which enclose spaces in which the flux is constant. The element of boundary-surface intersected by each elemental tube at the two boundary-surfaces encloses an equal number lines of magnetic flux, irrespective of the magnetic density at these points. By replacing the element of boundary-surface by its geometrical projection on a plane normal to the axis of the elemental tube, an equivalent equipotential surface is obtained at each end of the elemental tube. Any non-equipotential surface bounding an air-gap can thus be replaced by an equivalent equipotential surface composed of an aggregation of elemental equipotential surfaces which produce denticulations in the contour of the boundary-surface. It becomes possible, in this way, to evaluate magnetic reluctance and magnetic attraction by reference to summations of elemental magnetic tubes and without the necessity of considering directly the magnetic density of the magnetic field at any point. The potential of each elemental tube of magnetic force depends only upon the potentials at its ends, at the boundary-surfaces, it being entirely independent of the path followed by the tube in traversing the air-gap.

* * * * *

I. Introduction

The resultant magnetic effort, F, which is experienced by a soft iron body in a medium whose permeability is independent of the field, H, can be calculated by means of the known formula

$$F = \frac{1}{8\pi} \int_s \{2H(B, N) - N(H, B)\}\, dS \qquad (1)$$

in which N is the external unit vector which is normal to the surface-element dS, H and B being the vectors of the magnetic field and induction at the same point.

By means of equation (**1**), the resultant force, F, can be calculated whenever the distribution of the magnetic field along the external surface of the magnetic body is known. When that body is surrounded by air or like medium, the formula (**1**) can be further simplified; but even in that case, there are no analytical solutions in the majority of the cases of magnetic field distribution met with in practise, so that, as a rule, all that can be done is to obtain the graphical integration of equation (**1**) by deducing the values of the magnetic field from a chart of its lines of magnetic flux. It is possible, now, to determine these values within one per cent[2].

This method of evaluation of the quantity indicated by equation (**1**) is not free from error, owing to the points of saturation which occur at the sharp angles and at the narrow portions of the ferromagnetic material enclosing the slots.

For these reasons it seems worth while to inquire whether magnetic attraction could not be deduced directly from the lines of force shown in a magnetic figure without the necessity of first obtaining the components of the magnetic field and then recombining them tensorially. It so happens that this is possible within the entire range of validity of equation (**1**).

In the present paper the only case considered will be that of the attraction between ferromagnetic bodies that are separated by a medium like air, this case being of more immediate interest.

II. Transformation of the Physical Formula for Attraction

In (1), let $\{2H(B, N) - N(H, B)\} = P$. This quantity is a linear vectorial function of the normal unit-vector N. By putting this expression in the form $aP + bH + cN = 0$, it is seen that $P, H,$ and N, and also B when $B \| H$, are situated in the same plane. Moreover, the vector H bisects the angle formed between P and N (Fig. 1)[3] as is seen at once by taking the scalar product of P and H, and observing that $P^2 = B^2 H^2$. This allows P to be written in simpler form.

Let us use the term "*directed algebraical product*" of two vectors, H and B, to designate the vector the length of which is equal to the algebraical product of the scalar values of H and B, and the angle of which, with the

To be presented at the Midwinter Convention of the A. I. E. E., New York, N. Y., February 8-11, 1926.

3. See, for instance, A. Vaschy, "Théorie de l'Electricité," 1896, p. 64.

outward normal N, is equal to the sum of the angles, α, which H and B make with N; that is to say, 2α when $B \| N$. This vector, which is parallel to the same plane as N, H and B, will be symbolized by $(\overline{B\,H})_{2\alpha}$, so that for an iron body surrounded by air, formula (**1**) may be expressed in the following form:

$$F = \frac{1}{8\pi} \int_s B^2_{2\alpha}\, d\,S \tag{2}$$

Equation (**2**) may be considered a generalization of the ordinary formula of Maxwell, with which it becomes identical when $\alpha = 0$.

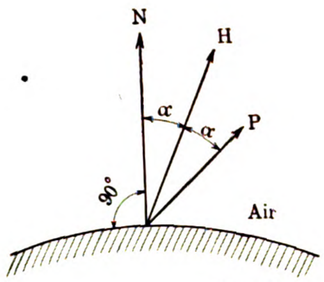

FIG. 1

It is seen at once that the algebraical value of the quantity to be integrated P, P is always equivalent to B^2 whatever may be the angle of incidence, α, of the magnetic field. In air, the tensorial ellipsoid consequently becomes a sphere. For the condition $\alpha = 0$, the integration is performed along a level surface, and $P = \overline{B_0{}^2}$ has the direction of N. For an angle of incidence $\alpha = 45$ deg., the elemental effort $P = \overline{B_{\pi/2}{}^2}$ is tangential to the surface. Finally, if the integration is performed along a surface generated by lines of magnetic flux, and more especially along a line of plane flux, we have

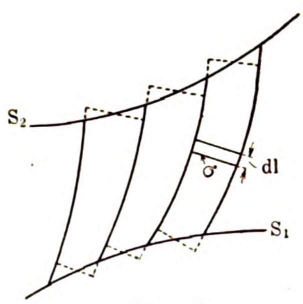

FIG. 2

$2\alpha = \pi$, and $P = \overline{B^{\,2}}$ is now directed in a direction contrary to that of N. Since the direction of P is obtained by simply reflecting N with respect to B, the application of formula (**2**) is a very simple matter.

III. Definition of the Reluctance Between two Non-Equipotential Surfaces which are Separated by an Air-Space

Let us subdivide the air-space between two non-equipotential surfaces, S_1 and S_2, (Fig. 2), into n very thin aliquot or subsidiary tubes having the reluctances $\rho_1, \rho_2, \rho_3, \ldots$, and let us replace the oblique bases of each tube by orthogonal bases having the same distance between centers. The elemental tubes being now limited by orthogonal bases, their reluctances can now be defined in the ordinary simple manner. It is known, moreover, that, in a medium of constant permeability, the magnetic energy of a Laplacian or vortex magnetic field is given by the volume-integral

$$W_m = \frac{1}{8\pi} \int B\,H\,d\,v$$

Integrating across the air-gap, along each tube, by tube-elements of sectional area σ and length $d\,l$, we will have

$$W_m = \frac{1}{8\pi} \sum_1^n \int B^2\,\sigma\,d\,l = \frac{1}{8\pi} \sum_1^n \phi_k{}^2 \int \frac{d\,l}{\sigma}$$

$$= \frac{1}{8\pi} \sum_1^n \phi_k{}^2\,\rho_k$$

But since the flux, ϕ_k, of each aliquot tube is equal to the nth part of the total flux Φ, we have

$$W_m = \frac{1}{8\pi} (\Phi_n)^2 \sum_1^n \rho_k = \frac{\Phi^2}{8\pi} R_0 \tag{3}$$

whence we deduce the total reluctance

$$R_0 = \frac{1}{n^2} \sum_1^n \rho_k \tag{3'}$$

or, more precisely,

$$R_0 = \underset{n\,=\,\infty}{\text{Limit}} \frac{1}{n^2} \sum_1^n \rho_k \tag{3''}$$

It is evident that, by defining the reluctance ρ_k of each tube in accordance with (3″), formulas (**3**) and (**3′**) will remain rigorously accurate, whatever may be the magnitude of the elemental tubes.

In principle, the reluctance R_0 between two non-equipotential surfaces may be defined by the aid of any drawing of magnetic tubes. If the fractional coefficients of the tubes be designated by $m_1 = \dfrac{\Phi}{\phi_1}$, $m_2 = \dfrac{\Phi}{\phi_3}$, ... we obtain, for R_0, the following more general expression:

$$R_0 = \sum_1^n \frac{\rho_k}{m_k{}^2} \tag{4}$$

The most frequent case is that where an arrangement of n tubes, conveying a total flux Φ, is composed of $n - 1$ aliquot tubes, each containing the flux $\phi_k = \dfrac{\Phi}{m}$ and a residual flux $\phi_n = \dfrac{\Phi}{m_n}$. The total reluctance then becomes equal to

$$R_0 = \frac{1}{m^2} \sum_{1}^{n-1} \rho_k + \frac{\rho_n}{m_n^{\,2}} \tag{5}$$

IV. Demonstration of the Equivalence of the Formula $F_l = \frac{\Phi^2}{8\pi}\,\frac{\delta R_0}{\delta l}$ to Formula (2)

Let us represent in cross-section (Fig. 3) the origin of a very thin tube, 2 - 3, and of the adjacent tubes, 1 - 2 and 3 - 4. Let us make the plane of the drawing parallel with the magnetic field in the air-gap B,

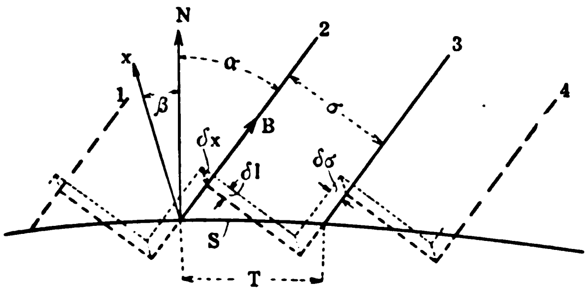

Fig. 3

and with the normal, N, with respect to the surface-element, S. The lines of magnetic flux being supposed to be very close to each other, no change will be caused in the reluctance of the tubes or in the external field if the oblique bases are replaced by orthogonal cross-sections through the same centers. Let us now displace the denticulated surface in a direction parallel to itself to the distance $d\,z$. All that need be considered is the projection $d\,x = d\,z \cos \eta$ of this displacement on the plane containing the vectors N and B, because any displacement of the surface-element S perpendicularly to that plane will have no influence on the reluctance of the tube under consideration. By taking any suitable unit of length for measuring the thickness of the tube in the direction perpendicular to the drawing, the width, σ, of the tube in the plane of the drawing can be made equal to its sectional area, and the intersections of its oblique base can be made equal to the surface-element, S.

Let (in Fig. 3) β designate the angle between $\delta\,x$ and the normal, N, and let α designate the angle of incidence of the vector, B. It will easily be seen that the displacement of the denticulated surface to the distance $d\,z$ causes in the tube of magnetic force a shortening equal to $d\,l = d\,x \cos(\alpha + \beta)$ in the direction of its length, and a decrease in its sectional area equal to $d\,\sigma = d\,x \sin(\alpha + \beta)$ over a length equal to $s \sin \alpha$. The result is that the reluctance of the portion of the tube thus modified is changed from $\rho = \frac{s \sin \alpha}{\sigma}$ to $\rho' = \frac{s \sin \alpha - \delta\,l}{\sigma - \delta\,\sigma}$, so that the variation in reluctance caused by the displacement of the surface-element, S, when $\sigma = s \cos \alpha$, and $s = S$, becomes equal to

$$\delta\,\rho = \frac{\delta\,x}{\sigma^2} \cos(2\,\alpha + \beta)\,S$$

$$= -\frac{\delta\,z}{\sigma^2} \cos \eta \cos(2\,\alpha + \beta)\,S \tag{6}$$

Now, let $\frac{\Phi}{m_k} = B\,\sigma$ represent the magnetic flux in any tube. The summation of the values $\frac{\Phi^2}{8\,\pi}\,\frac{1}{m_k^2}\,\frac{\delta\,\rho_k}{d\,z} = -\frac{1}{2\,\pi} B^2 \cos(2\,\alpha + \beta)\,S$ along the whole surface will then, with the aid of (**4**), give us

$$\frac{\Phi^2}{8\,\pi} \sum \frac{1}{m_k^2}\,\frac{\delta\,\rho_k}{\delta\,z} = \frac{\Phi^2}{8\,\pi}\,\frac{\delta\,R_0}{\delta\,z},$$

from which, by passing to the limit, we obtain

$$\frac{\Phi^2}{8\,\pi}\,\frac{\delta\,R_0}{\delta\,z} = -\frac{1}{8\,\pi} \int_s B^2 \cos(2\,\alpha + \beta) \cos \eta\, d\,S \tag{7}$$

It now becomes immediately apparent that the quantity under the integral sign is nothing more than the projection of the vector, $P = \overline{B_{2\alpha}}^{\,2}$ upon the direction of $\delta\,z$. Therefore, the formulas (**2**) and (**1**) lead to the same effort in any given direction δz, as the formula $\frac{F}{z} = \frac{\Phi^2}{8\,\pi}\,\frac{\delta\,R_0}{\delta\,z}$, and the three formulas are consequently equivalent to each other. This result can also be expressed vectorially as follows:

$$-\frac{\Phi^2}{8\,\pi} \times (\text{Virtual gradient of } R_0) = \frac{1}{8\,\pi} \int_s \overline{B_{2\alpha}^{\,2}}\, d\,S.$$

We shall now show that the attraction between two

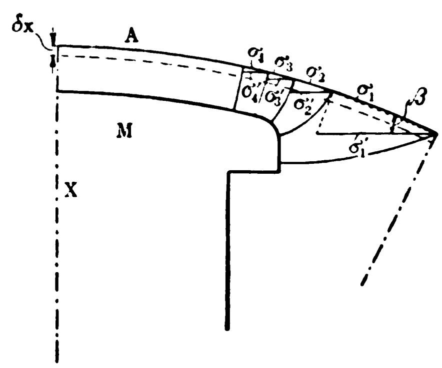

Fig. 4

bodies depends only upon the field that is common to both of them and that it can be evaluated without knowing the leakage-field.

V. Calculation of Magnetic Attraction by Means of the Common Field Only

A. *Unsaturated circuits.* Let us consider the attraction in a radial direction between a field-magnet M

with salient poles and the armature (or stator) A (Fig. 4), on the assumption that $\mu = \infty$ in the iron. For this purpose, let us suppose a virtual decrease equal to δx in the air-gap, as if the armature were brought closer in the direction of the axis (X) of the pole, and let us, for a moment, assume as being true, the physical figment that the external field is not disturbed in consequence of the displacement in question (δx). Under such conditions, the length of each tube of magnetic force will be decreased by an amount equal to $\delta x \cos \beta$, where β designates the angle between the normal to the surface S at the point under consideration and the direction of δx. Therefore, if σ is the sectional area of the tube as it emerges from the surface of A, the variation of its reluctance, ρ, will be $\delta \rho = -\frac{\delta x \cos \beta}{\sigma}$. The portion of the virtual energy pertaining to this tube, when ϕ is the flux, consequently becomes equal to $\delta T = \frac{\phi^2}{8\pi} \frac{\delta x \cos \beta}{\sigma} = \frac{B^2}{8\pi} \delta x \cos \beta \, \sigma$, and the elemental force along δx will be equal to

$$f_x = \frac{B^2}{8\pi} \sigma \cos \beta$$

which is evidently the projection upon δx of the force which is normal to σ, namely, $f = \frac{B^2 \sigma}{8\pi}$, in perfect accordance with formulas (**1**) and (**2**).

Inasmuch as the common flux ϕ, is generally the primary information available in practise, it is important to note that the total force of attraction F_x can be obtained without any integration, when the drawing shows m isometric tubes, by obtaining, along the armature, the value of the sum

$$F_x = -\frac{\Phi^2}{8\pi} \frac{\delta R_0}{\delta x} = \frac{\Phi^2}{8\pi} \frac{1}{m^2} \sum \frac{\cos \beta}{\sigma}$$

All that is necessary, therefore, is to obtain, at the place where the end-section, σ, of each tube emerges from the polar surface (A), the segments $\sigma' = \frac{\sigma}{\cos \beta}$, which are marked off by projection upon a line perpendicular to the direction of δx (see Fig. 4) by the normals to the chord of σ drawn (dotted in Fig. 4) between its two opposite edges. We thus obtain

$$F_x = \frac{\phi^2}{8\pi} \frac{1}{m^2} \sum \frac{1}{\sigma'} \qquad (8)$$

The degree of precision of F_x naturally depends upon the number of isometrical tubes into which the useful flux is subdivided. When the drawing comprises $n - 1$ tubes, each containing the flux $\phi = \frac{\Phi}{m}$, and a residual tube containing the flux $\phi' = \frac{\Phi}{m'}$, it is evident that we shall have

$$F_x = \frac{\Phi^2}{8\pi} \left\{ \frac{1}{m^2} \sum_{1}^{n-1} \frac{1}{\sigma_k - 1} \quad . \; . \; . \; . + \frac{1}{m'^2} \frac{1}{\sigma_n'} \right\} \qquad (8')$$

Let us now reverse the roles by bringing the field-magnet closer to the armature by the distance δx in a direction parallel to the axis of the pole. In order to make the physical figment plausible, we must now assume (Fig. 5) that the magnetic field is displaced bodily with its excitation-winding, which is assumed to have a fixed relation with respect to the pole (M). The line of flux 1 - 2 which starts from the neutral point, will be displaced upward by the distance δx in a direction parallel to itself, toward 1′ - 2′; and we now have to find the difference between the reluctances between the contours 1 - 2 - 3 - 4 and 1′ - 2′ - 3′ - 4′. But, instead of measuring these differences along the armature, we shall totalize them along the pole and the line 1 - 2. Along the polar surface, as far as the line 1′ - 2′, we shall obtain, as before, the segments $\sigma' = \frac{\sigma}{\cos \beta}$, where σ designates the sectional area of the tubes measured where they emerge from

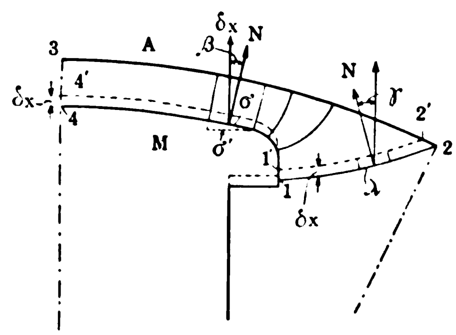

FIG. 5

the pole and β designates the angle between the normal N, to the chord of σ and the direction of δx. For the tube at the extreme right hand, there will be, in addition, a decrease in sectional area equal to $\delta x \cos \gamma$, where γ designates the angle between the direction of δx and the normal, N, to the line of flux at the point considered. The variation of reluctance per element of tube of length, λ, which results in the case of the last tube, in addition to the shortening, will be equal to

$$\delta \rho' = \frac{\lambda}{\sigma - \delta x \cos \gamma} - \frac{\lambda}{\sigma} = \frac{\lambda}{\sigma^2} \delta x \cos \gamma,$$

and the corresponding decrease of attractive force will be equal to

$$f_x' = -\frac{\phi^2}{8\pi} \frac{\delta \rho'}{\delta x} = \frac{B^2}{8\pi} \lambda \cos \gamma,$$

which is the geometrical projection on the pole-axis of a

force, $-\dfrac{B^2 \lambda'}{8\pi}$ which is normal to λ. The same term may also be obtained with equations (1) and (2), by making the surface-integral pass over the polar face and the line of flux $1-2$ which ends at the neutral point.

The tube of magnetic force that is contiguous with the line $1-2$ is composed (Fig. 6) of two squares, the mean sectional areas of which may be replaced approximately by the chords, λ_1 and λ_2, of their average lengths. The quantities $\lambda_1' = \dfrac{\lambda_1}{\cos\gamma_1}$ and $\lambda_2' = \dfrac{\lambda_2}{\cos\gamma_2}$ correspond to and can be obtained directly from segments cut off from a horizontal line (Fig. 6) by the perpendicular lines erected at their extremities in each case; and with the aid of these quantities, we finally have, in the case of m aliquot tubes of magnetic force,

$$F_x = -\frac{\phi^2}{8\pi}\,\frac{\delta R_n}{\delta x}$$

$$= \frac{\phi^2}{8\pi}\,\frac{1}{m^2}\left\{\sum\frac{1}{\sigma'} - \left(\frac{1}{\lambda_1'} + \frac{1}{\lambda_2'}\right)\right\} \quad (9)$$

It is therefore possible to evaluate the virtual derivative,

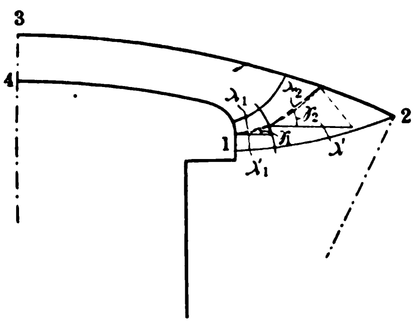

FIG. 6

$\dfrac{\delta R_n}{\delta x}$, *from the original drawing of the magnetic field, without representing the displacement δx and without introducing the components of the magnetic field.*

It should be noted that the virtual work is equal to the energy contained in the zone involved only when the armature is displaced. If, instead, the magnetic field-pole and its winding are displaced, the magnetic energy contained in the area embraced by the polar base of the useful flux, 1 - 4 (Fig. 5) should be reduced by an amount equal to the potential energy contained in the zone embraced by the extreme lines $1-2$ of the common flux.

Example. Let us take as an example, the magnetic figure (Fig. 7) reproduced from Fig. 19 in the "*Revue Generale de l'Electricite*," 1923, Vol. XIV, p. 397. After the fourth magnetic tube, counting from the neutral point, the lines of magnetic flux are radial, and they constitute, between that point and the polar axis, 6.4 unit tubes; so that the common flux, ϕ, per half pole consists of 10.4 unit-tubes. The air-gap being equal to 1.2 cm., and the polar half-pitch being equal to 9 cm., we have, for the sectional areas along the armature, reckoned from the neutral point:

2.85 cm.; 0.97 cm.; 0.71 cm.; 0.62 cm.; 6.4/0.6 cm.

The fractional coefficients are $m = 10.4$ for the first four tubes and $m' = 10.4/6.4$ for the last tube; so that, for the radial attraction per half polar pitch, we have:

$$F_x = \frac{\phi^2}{8\pi}\,\frac{1}{10.4^2}\left[\frac{1}{2.85}+\frac{1}{0.97}+\frac{1}{0.71}+\frac{1}{0.62}+\frac{6.4}{0.6}\right]$$

$$= \frac{\phi^2}{8\pi}\,\frac{1}{10.4^2}\,.\,15.06$$

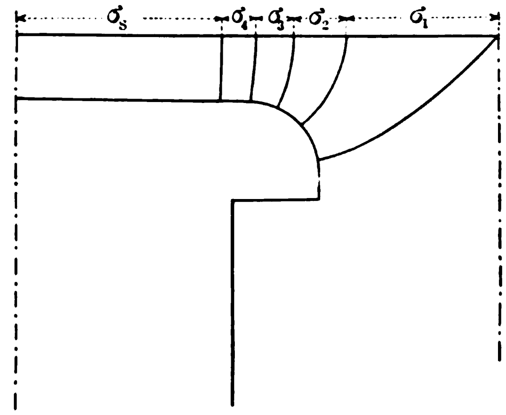

FIG. 7—DETERMINATION OF THE MAGNETIC ATTRACTION OF THE ARMATURE

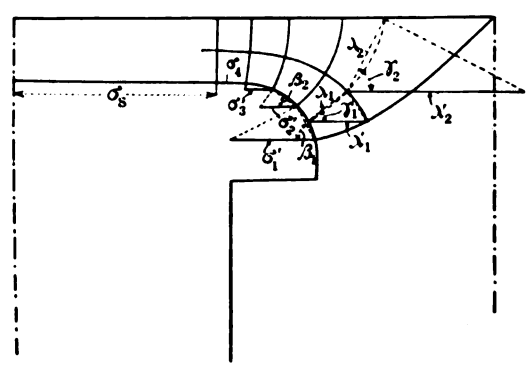

FIG. 7A—DETERMINATION OF THE MAGNETIC ATTRACTION OF THE FIELD

Let us now start from the field-pole. The bases of the first three tubes that emerge from the polar surface are no longer horizontal, and it is necessary to begin by erecting perpendicular lines on the chords of σ and to obtain in a horizontal direction (see Fig. 7A) the values of $\sigma' = \dfrac{\sigma}{\cos\beta}$; which gives us the following values; $\sigma_1' = 1.57$ cm.; $\sigma_2' = 0.70$ cm.; $\sigma_3' = 0.34$ cm.; and we can then point off directly the values $\sigma_4 = 0.55$ cm. and $\sigma_5 = 6.4/0.6$ cm. We still have to obtain,

on the line of median flux of the first tube (shown dotted), the segments $\lambda_1' = \dfrac{\lambda_1}{\cos \gamma_1}$ and $\lambda_2' = \dfrac{\lambda_2}{\cos \gamma_2}$, which may be cut off along any horizontal lines whatever by the lines perpendicular to the chords of the curvilinear elements λ_1 and λ_2 erected at their extremities. These values are found to be: $\lambda_1' = 1.10$ cm., and $\lambda_2' = 3.40$ cm.

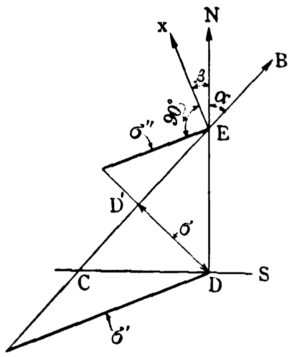

Fig. 8

The radial effort exerted per half pole pitch is thus found to be equal to

$$F_x = \frac{\phi^2}{8\pi}\,\frac{1}{10.4^2}$$

$$\left[\frac{1}{1.57}+\frac{1}{0.70}+\frac{1}{0.54}+\frac{1}{0.53}+\frac{6.4}{0.6}-\frac{1}{1.10}-\frac{1}{3.4}\right]$$

$$= \frac{\phi^2}{8\pi}\,\frac{1}{10.4^2}\cdot 15.20$$

The difference between this value and the preceding one is barely one per cent; which seems satisfactory if we bear in mind that for the whole of the half distance between the two poles only one tube of magnetic force has been assumed. The armature in Fig. 7, was assumed to be rectilinear, instead of curved, in order to simplify the comparison with the algebraical formula which can be established for that case. The inclination of the polar axes does not in any way modify the method of calculation, and the same results should always be obtained whether we start from the armature or from the field-pole.

B. Saturated Circuits. The physical figment that a displacement does not disturb the external field leads us immediately, by the aid of (**6**), to expressions for an armature in which there is no current,

$$F_x = \frac{\phi^2}{8\pi}\sum\frac{\cos(2\alpha+\beta)}{m^2\,\sigma\cos\alpha}, \qquad (\mathbf{10})$$

and for a field-pole which is driving its field without alteration,

$$F_x = \frac{\phi^2}{8\pi}$$

$$\left\{\sum\frac{\cos(2\alpha+\beta)}{m^2\,\sigma\cos\alpha}-\frac{1}{m_n^2}\left(\frac{\lambda_1}{\cos\gamma_1}-\frac{\lambda_2}{\cos\gamma_2}\right)\right\} \qquad (\mathbf{10'})$$

Let us consider (Fig. 8) the base $C\,D$ of a tube having the thickness $D\,D' = \sigma$, which emerges from an element $C\,D$ of the surface, S, of the iron, at an angle α with respect to the normal $D\,E$ to $C\,D$. We can then obtain the projection of the superficial force f_x, corresponding to this tube, in a direction x, forming an angle β with $D\,E$, by constructing directly

$$f_x = -\frac{\phi^2}{8\pi}\cdot\frac{\delta\rho}{\delta x} = \frac{\phi^2}{8\pi}\,\frac{\cos(2\alpha+\beta)}{\sigma\cos\alpha}.$$

But it is often easier to decompose

$$\frac{\delta\rho}{\delta x} = \frac{1}{\sigma'} - \frac{1}{\sigma''}$$

$$= \frac{\cos(\alpha+\beta)}{\sigma} - \frac{\tan\alpha\sin(\alpha+\beta)}{\sigma}$$

and to obtain σ' and σ'' from Fig. 8 by cutting off segments on the perpendiculars to x emerging from D and E through the mean vector of the field B passing through C on the one hand and through the normal to the vector, passing through D, on the other hand. In the case of the field-pole it is still necessary to add the terms $\dfrac{\lambda}{\cos\gamma}$ which come from the extreme tubes of the common flux and which are determined as before.

When the magnetic figure comprises one or more lines of equal potential, the calculation becomes simpler by making the summation along any contour whatever, such as $A\,B\,C\,D\,E$ (Fig. 9) composed of lines of flux and of lines of equal potential, ending at the neutral points of the armature, or, in more general manner,

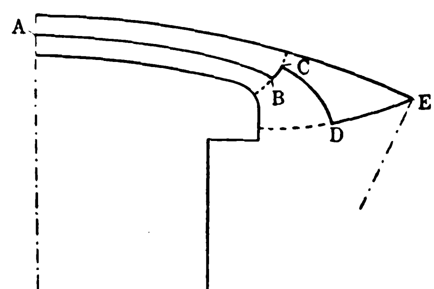

Fig. 9

ending at boundary points of the common field. The values of $\sigma' = \dfrac{\sigma}{\cos\beta}$ and of $\lambda' = \dfrac{\lambda}{\cos\gamma}$ may be obtained, as explained in paragraph A, from the sections σ on the equipotential lines and the segments λ on the isometric lines of flux, by noting that the terms

$\frac{1}{\sigma}$ are of the same sign as the areas swept over, whereas the terms $\frac{1}{\lambda'}$ are of contrary sign.

The equivalence of the process can be easily demonstrated by transforming, by means of the generalized form of Green's theorem, the surface-integral (**1**) into a volume-integral:

$$\int_s S\, P\, d\, S = \int \{2\, H \operatorname{div} B - H^2 \operatorname{grad} \mu - 2\,(B, \operatorname{rot} H)\}\, dv \qquad (\mathbf{11})$$

In the space in the air-gap which is traversed by the useful flux we have, inside any closed aerial surface, $\operatorname{div} B = 0$; $\operatorname{grad} \mu = 0$; $\operatorname{rot} H = 0$; therefore, we will have

$$\int_S P\, d\, S = 0 \qquad (\mathbf{12})$$

Let us now suppose that the air-gap is swept over once by the surface of the armature, for a distance equal to one polar division $0_1\, I\, 0_2$ (Fig. 10) and a second time by a string of any kind whatever, such as 0_1 II 0_2 which extends between the same points 0_1 and 0_2 of the armature. Multiplying (**12**) scalarly by the displacement $\overline{\delta\, x}$, and integrating along the closed contour 0_1 I 0_2 II 0_1, we have:

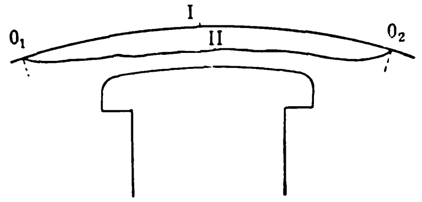

FIG. 10

$$\int_s (\overline{\delta\, x}, \overline{B_{2\alpha}{}^2})\, d\, S = 0; \text{ whence}$$

$$\int_{0_1 I\, 0_2} (\overline{\delta\, x}, \overline{B_{2\alpha}{}^2})\, d\, S = \int_{0_1 II\, 0} \overline{\delta\, x}, \overline{B_{2\alpha}{}^2})\, d\, S; \qquad (\mathbf{13})$$

or, on bringing (**13**) closer to the identity (**7**), we see that

$$(\delta\, R_0)_{\mathrm{I}} = (\delta\, R_0)_{\mathrm{II}}$$

It is, therefore, possible to determine the virtual variation of the reluctance, on the assumption that the air-gap is cut through by any contour whatever passing through the neutral points 0_1 and 0_2 of the armature. This manner of proceeding has advantages in the case of windings placed in slots (as in turbo generators).

The physical formulas for magnetic attraction are not much used in practise. Is this due to the hypotheses used in physics? It cannot be denied that, at first glance, our practical intuition, clarified by the idea of the magnetic circuit, finds it difficult to accept the figment which excludes any disturbance of the field during a virtual displacement. But this figment, although it may lead to a state of unbalance, is, in general, justified by observing that, in accordance with Thomson's theorem, one of the two neighboring states of distribution corresponds to a minimum of potential energy.

VI. APPLICABILITY OF THE DIFFERENT FORMULAS

Theoretically, formulas (**1**) and (**2**) enable the attraction to be evaluated whenever the magnetic field in the air-gap is known along the whole surface. But since no analytical solutions that are of interest in practise are available in the majority of cases the best we could hope to do would be to obtain the integration of these formulas graphically after the values of the magnetic flux have been deduced from a drawing of the lines of flux. And even this calculation becomes uncertain in the neighborhood of the slots for the windings, on account of the points of saturation found at the sharp corners and narrow parts of the cores that close around the slots. On that account the integration is rendered possible only when the surface of integration is situated at a suitable distance from the limiting surfaces. It is therefore necessary to have a complete survey of the magnetic field in the air-gap. Moreover, formulas (**1**) and (**2**) are no longer applicable when the surface of integration passes through a medium the magnetic permeability of which is a function of H.

The formula $F_1 = \frac{\phi^2}{8\,\pi}\,\frac{\delta\, R_0}{\delta\, l}$ makes it possible to evaluate the magnetic attraction in the case of any ferromagnetic body surrounded by a medium of constant permeability (air) without the necessity of taking into account the components of the field. The permeability of the body may or may not depend upon the field. In the form in which the formula is completed by the saturation-term[4], it can also be used when the permeability of the external medium depends upon the field. It is then possible, moreover, to do without the magnetic figures of the lines of flux, provided the reluctance, R_0, of the air-gap is known as a function of the extent l, of the air-gap, It is also more easy, by means of this formula, to note critical values of the effort of attraction near points of contact, where the attraction may become more than double, even when the flux is assumed to be maintained constant by means of equipotential connections.

VII. CONCLUSIONS

The magnetic effort exerted upon an assemblage of ferromagnetic bodies and of currents, surrounded by air as a medium, is determined by the corresponding fluxes, ϕ and by the virtual gradient of their air-reluctances, R_0.

The formula $F_1 = \frac{\phi^2}{8\,\pi}\,\frac{\delta\, R_0}{\delta\, l}$ is as exact and as

4. This case is treated in "*Revue Générale de l'Electricité*," Vol. XV.

general as the formulas of physics. It has the advantage over them that besides giving an algebraical solution, it renders possible the evaluation of magnetic attraction by the direct utilization of the lines of magnetic flux of a magnetic figure, without the necessity of first determining the components of the field and then recombining them tensorially.

In a general way, the attraction between two bodies depends only upon the field common to them both. That is still true when the two fields have nothing more in common than their lines of separation (the case of the ideal short-circuit); and the mutual magnetic effort is then determined entirely by the value of the field along these lines of separation.

Discussion at Pacific Coast Convention

APPLICATION OF ELECTRIC PROPULSION TO DOUBLE-ENDED FERRY-BOATS

(KENNEDY AND SMITH)

SEATTLE, WASHINGTON, SEPTEMBER 16, 1925

H. F. Harvey, Jr.: About the only comment which I have to offer is that sufficient emphasis has not been laid on the maneuvering feature. With direct control from each pilot house it is very evident that the one in charge can maneuver the boat more easily than by means of the ordinary signals to the engine room.

I believe that thus far most ferry-boats with electric drive are used on fairly long runs. Such runs do not show to advantage the speedier maneuvering, either when entering or leaving the slips. For short runs as between New York and Jersey City, or between Camden and Philadelphia, electric drive would show a decided advantage in this respect.

Ferry-boats are usually operated in congested waters where it is very necessary to have close control of the vessel in order to avoid accidents. Electric drive, I believe, affords quicker stopping and reversing than any other drive. Too much emphasis, therefore, cannot be placed upon the superior maneuvering qualties of electrically driven ferry-boats.

F. K. Kirsten: There has been no mention made in the paper as to the design of the propellers involved in ferry-boat propulsion. It seems that these boats are designed to travel in either direction with practically the same propeller showing. As a consequence, some design must be used on these particular ferry-boat propellers differing from that used in ordinary steamers. I would like to know if any particular statements could be made in that direction.

M. J. Whiteman: I should like to know if it is possible with a ferry-boat having four-propeller drive to rotate the boat on a center or pivot in order to make quick turns.

A. Kennedy Jr.: Mr. Whiteman asked if it is possible with an electrically-driven ferry-boat to pivot the boat in order to make quick turns, and also the number of electrically driven ferry-boats that are in operation. All electrically driven ferry-boats use the same method of steering as that used on reciprocating steam engine driven ferry-boats, that is, they use one rudder. I do not know of any way to make a ferry-boat pivot in order to make quick turns unless some change is made in the design of the boat.

At the present time there are eight electrically driven ferry-boats in operation, three in New York, four in San Francisco, and one at Poughkeepsie. These, I believe, are the only ones, but of course, others are being considered.

Professor Kirsten asked whether or not it was necessary to modify the design of the propellers for electrically driven ferry-boats. Normally, with steam engine driven ferry-boats, a compromised propeller design is used, as it is necessary to use the face and back of the blades. A good deal of work has been done trying to improve the over-all propulsive efficiency by decreasing the amount of power required to drive the forward propeller. As far as I know, no one has been able to improve the over-all propulsive efficiency by using this specially designed propeller, but they have reduced the power required to drive the forward propeller.

With electric drive it is possible to use a standard propeller for the simple reason that the bow propeller does not do any work. Only the face is used of the propeller for driving, whereas with the reciprocating steam engine connected to a through shaft a special design is made as the back of the blades is normally used on the forward propeller to assist in driving the ferry-boat.

A HIGH-VOLTAGE DISTRIBUTING SYSTEM[1]

(GLEN H. SMITH)

SEATTLE, WASHINGTON, SEPTEMBER 17, 1925

M. T. Crawford: In Mr. Smith's paper he has referred to the use of a high-voltage primary distribution system, and some reference is also made in Mr. Kelley's paper, to the use of 12,000-volt primary system.

It occurs to me that in following a far-sighted policy, there would be some question as to whether such a high voltage should be used for primary distribution in a city area. There are several angles to the situation. Fundamentally high voltages are of value to cover distances. In distributing light and power in a large city, very large blocks of load can be obtained within short distances. In suburban areas around the large city, considerable distance has to be covered before any considerable amount of power is obtained. For that reason it has been the practise of the company with which I am connected to employ the high-voltage distribution primarily in the suburban area where one distributing substation can serve a radius of 10 to 15 mi., without having any unusually large load entrusted to its care.

In looking into the future of city distribution, we anticipate loads of such size and magnitude as to give load densities which would result in several hundred thousand kilowatts or more being supplied by one distributing substation. If 10,000 or 15,000 volts is used for primary purposes and if sufficient area is covered to make full economic use of such voltage, this would, it is felt, entrust more different consumers' services into the hands of this one substation than might be considered good policy, considering the importance of continuity of service to such a large number of people. The other angles to the use of the high voltage are, first, that it takes considerably more pole space, second, that transformers are more expensive, and third, that cable costs are higher. Such portions of the systems as have to be either submarine or underground will have to be handled by cables, and statistics collected by the National Electric Light Association indicate that in operating a large mileage cable failures increase rapidly in proportion to the voltage.

The high-voltage distribution system in the city of Seattle has worked out very satisfactorily and I think the engineers are to be commended for having secured such results. I would like to ask Mr. Smith, however, if the increase in railway load which has recently occurred and will continue will not result in fluctuating loads on his 26-kv. network, which will introduce

1. A. I. E. E. JOURNAL, October, 1925, p. 1104.

some difficulties in regulation and, may force a change in this policy. We have found where our load is largely lighting, we can use 13-kv. primary distribution very successfully, installing a 13-kv. automatic voltage regulator at the substation, to regulate the entire bus, serving an area within a 15 mi. radius with little or no supplementary regulation.

Where fluctuating power loads are to be handled together with a considerable amount of railway, this has not been possible, and it has been more economical, besides seeming to us better policy from the far-sighted point of view of future loads and service to the public, to install distributing stations and distribute at a lower primary voltage.

C. A. Heinze: There has been considerable discussion in these distribution papers on the matter of distribution at voltages of approximately 33 kv. Mr. Smith describes one at 26 kv. which is practically 33 kv. In Los Angeles, we have an area that is very lightly loaded, with the result that to place a network of low-voltage lines over that area would have called for considerable investment, not warranted by revenues. We were rather fortunate in this particular case to have two power houses, one on each side of the area. This permits us to carry straight line voltage on the 33-kv. lines between these two power houses.

Now, with a system plan, the system can be developed as follows: The first step to feed consumers from this 33-kv. line is to put a transformer on a pole, stepping down from 33 kv. to 4.4. kv., three-phase, three-wire delta. From this transformer we distribute a distance of from one to two miles each way, picking up the small consumers along the way. Now, as the load increases, the transformer becomes too big for the pole, the transformer is then mounted on the ground. This is the second step. With growth continuing, it is then necessary to split the 4.4-kv. line into feeders. As growth continues we go to regulated feeders. By the time we have two or more regulated feeders, it then becomes necessary to house the equipment and provide substation space. Having reached the substation period, the first step would be the use of automatic reclosing switching equipment. As the number of stations increase the automatic reclosing equipment is supplemented with supervisory control from one centrally located station.

I was very much interested to note in Mr. Kelley's paper on the Commonwealth Edison System of Chicago, that they are using a similar type of distribution.

A very important consideration in the design of substations is the proper provision for future growth and extensions. The most satisfactory way to accomplish this is to design the substation on the unit plan. Additions can be made to the initial unit by the addition of one or more similar units such that in the end the station building and interior design represent a balanced electrical and architectural design. Many of you have seen a substation, very beautiful in the beginning, at the end of five or ten years having several irregular additions built around—marring its original symmetry—in order to take care of the extensions and expansions required. This, because we didn't discover or take them into account at the beginning.

Glen H. Smith: I have to thank Mr. Crawford, in his reference to my closure, for bringing out some of the questions that we considered in deciding on our distributing system. I can only say that they are questions, and that we decided them one way though often they are decided the other way. The decision as to the voltage of a circuit depends probably more on the load than it does on the size of the district served.

We find that poles are more involved with lower-voltage circuits than they are with high-voltage circuits, because of the greater number of circuits, although high-voltage circuits take more pole space per circuit.

I can't answer the question as to the effect of fluctuating railway load on our voltage regulation as the railway stations are still connected by special 13,000-volt feeders direct from the station, nothing else being connected but those stations. We have, though, heavier loads than they represent connected to the high-voltage system without any trouble. We expect that the railway stations will help rather than hinder us, by furnishing synchronous capacity to hold the 26,000-volt busses to the proper voltage level in more than the original three points.

ON THE NATURE OF CORONA LOSS[1]

(HESSELMEYER AND KOSTKO)

SEATTLE, WASHINGTON, SEPTEMBER 17, 1925

R. W. Sorensen: The peculiar curves for Fig. 1 of this paper have to be used in charting the results because a piece of tracing cloth, stretched over the end of the cathode-ray tube, must have lines, as shown, drawn on it to correct for the curvature of the tube and the distortion of the wave.

H. J. Ryan and J. S. Carroll: In the paper on The Hysteresis Character of Corona Formation, by Henline and Ryan,[2] presented a year ago at the Pasadena Convention of the Institute, the authors, in arriving at the existence of a space charge about a conductor in corona, worked at a disadvantage because they had not actually located the radial position of such space charge with respect to the conductor. During the past year two of our graduate students, Mr. Hesselmeyer and Mr. Kostko, proposed to study the radial location of the space charge by the simple plan of a concentric barrier that would limit the radial distance of the space charge from the conductor surface. They would use an isolated barrier cylinder mounted concentrically as specified in their paper; they would obtain the corresponding $E-Q$ relation and then change the radius of the barrier and obtain the $E-Q$ relation again. This plan would be continued over a wide range for the radius of the barrier in order to determine the manner in which the character of the $E-Q$ relation would change with the barrier radius. The purpose of this undertaking was to find out whether the character of the $E-Q$ relation, when barriers were used that bound the space charges to definite radial positions, would approach the character in form and area of the $E-Q$ relation as found for widely separated parallel conductors surrounded by no barriers.

When the work was completed and this paper was prepared by the authors and studied by us, the following point of view developed: The areas in units of energy, given by the Hesselmeyer-Kostko $E-Q$ diagrams, could be expressed in terms of the voltage and the capacitances of the conductor to the space charge and of the conductor to the grounded cylinder or neutral plane. The corresponding power would be the product of the energy by the frequency. Henline and Ryan, in their paper a year ago, had given the corresponding equation for the energy per cycle in terms of voltage and but one value of capacitance, viz., that of the conductor to the neutral plane. It was manifest that, by combining these equations, one could isolate the value of the capacitance of the conductor to the space charge.

Mr. Kostko then derived the equation for the power lost in corona using a barrier, as follows:

$$P = 4 f C (E E_0 - E_0^2) \frac{1}{\frac{C''}{C'} - 1} \tag{2a}$$

wherein

E, is the value of the crest voltage,
E_0, the value of the critical voltage,
C, the capacitance from conductor to neutral,
C'', the capacitance from conductor to the space charge, and
f, the frequency.

The corresponding equation given in the Pasadena paper a

1. A. I. E. E. JOURNAL, October, 1925, p. 1068.
2. A. I. E. E. JOURNAL September 1924, page 825.

year ago, wherein the term C'', capacitance of conductor to space charge was not used, was:

$$P = 4 f C (E^2 - E E_0) \quad (2)$$

By combining and reducing these equations the value of the capacitance of the conductor to the space charge was found to be:

$$C'' = C\left(\frac{E_0}{E} + 1\right) \quad (3)$$

If the radial distance from the conductor to the cylindrical space charge be D_r, and the radius of the conductor r, then the value of C'' will also be:

$$C'' = \frac{0.00368}{\log_{10}\left(\frac{D_r}{r}\right)} \quad (2d)$$

By combining equations (2c) and (2d)

$$\log\left(\frac{D_r}{r}\right) = \frac{0.00368}{C\left(\frac{E}{E_0} + 1\right)} \quad (2c)$$

and

$$\log D_r = \log r + \frac{0.00368}{C\left(\frac{E}{E_0} + 1\right)} \quad (2f)$$

wherein:

D_r and r are in inches

C and C'' in farads per 1000 feet of conductor.

Equation (2f) was applied to one of the corona loss-voltage curves[3] given by Professor Harding's Pasadena 1924 paper[4] the following locations of the space charge were obtained:

e Kv., r. m. s. swe. to neutral	D_r in inches	Kv. per inch, r. m. s.	
		Conductor to space charge	Between pointed electrodes*
140	9.5	14.8	10
165	12.0	13.8	10
220	18.9	11.6	9.9
260	24.1	10.8	9.8
300	29.8	10.	9.8

*A. I. E. E. Standardization Rules, 1912.

As a check upon this understanding of the distance of the space charge from a conductor in corona the following trial was made: In front of a pointed electrode at a distance of 9.5 inches a grid of fine wires was mounted. Alternate wires were electrically connected, thus forming two groups of wires each interlaced with the other. To the groups, a 20-volt, dry-cell battery was connected through a portable galvanometer; 60-cycle alternating voltage was then applied between the pointed conductor and grounded plate and the indications of the galvanometer noted as the value of the voltage was raised. The galvanometer indicated that no current was set up through the air between the two groups of wires in the grid until the voltage was raised to an effective value of 110 kv. Thereafter the current increased at the rate of 0.1 microampere per kilovolt until the value of three microamperes was attained at 140 kv. As a slight further increase of the voltage was made, the current through the air between the grid wires rose to eight microamperes. And then, as the voltage increase was continued, there was no corresponding continuation of increase of current. This is precisely the sort of thing that should happen if the foregoing understanding of the existence and position of a space charge about a conductor in corona is correct.

The matter was tried out by another plan: The space charge was reversed while the voltage increased from the critical value E_0 to the crest value, E, in a corresponding interval $\Delta t = t - t_0$. During such interval, Δt, electrons must travel from the conductor to the location of the space charge when the potential of the conductor is negative, and vice versa when positive. When the electrode in corona is the point of a conductor, the resulting luminosities produced by the migration of the electrons as just specified might be intense enough to be visible in full darkness to or near to the radial position of the space charge. On trial, such was found to be the case.

Another reasonable conjecture in regard to action due to the space charge was encountered: Voltage was applied between a pointed conductor and a grounded metal plate. As the voltage was raised corona filled a conical space that expands from the point toward the plate through distances in relation to voltages that correspond roughly to those given in the above table. As the voltage crests occur the space charges and point potentials have the same sign, while the signs of the space charges and bound charges induced in the grounded plate as opposing electrode are opposite. The consequence is that the intensity of the electric field between the space charge and the point has been reduced and that between the space charge and plate has been correspondingly increased. The outcome must be that, as the voltage is raised, critical electric stress will be encountered in the air between the space charge and the plate beyond which the intervening air must be ionized and rendered conductive. On trial, this too was found to be the case. As the voltage is raised, the faintly luminous cone develops, attached to the point with rounded base thrust forward. Then, as the rise of the voltage continues and the growth of the cone moved its base to a position whereat it was somewhat nearer the plate, a faint pillar of light suddenly extended from the cone to the plate; the air column connecting the point to plate had been ionized and spark-over and arcing followed with slight further increase of voltage.

And so, thus far every plan that has occurred for authenticating the existence and position of the alternating space charges established and maintained about a conductor in corona due to 60-cycle voltages when tried out, has resulted in corroboration of the understanding as given.

H. S. Bates: I should like to ask Mr. Hesselmeyer if there will be any means of accurately measuring corona loss? I wish to ask also what is the best method of preventing it?

C. T. Hesselmeyer and J. K. Kostko: The experiments of Prof. Ryan and Mr. Carroll are interesting not only because they prove the existence of a space charge, but also because they suggest experimental arrangements for a quantitative study of the distribution of the space charge and the field. It is easy to set up equations theoretically determining these two elements (Poisson's equation and equation of continuity); but numerical solutions could only be obtained by reducing these general equations to simpler types, based on the results of a preliminary experimental study of the problem.

In the author's opinion the most accurate method of measuring corona losses available at present is by means of the high-voltage wattmeter developed at Stanford University and described in several Institute papers by Mr. Carroll and others.[3] In Fig. 17 of the paper the losses measured with this wattmeter are compared with the losses obtained by a very different

3. In applying these equations it should be remembered that the voltage must be taken at a value sufficiently above the critical voltage to ensure that a fixed brush pattern has been formed and the value of C is a constant as presented in the Pasadena paper.

4. *Corona Losses between Wires at Extra High Voltages*, by C. F. Harding, A. I. E. E. JOURNAL, October, 1924, page 932.

3. *Power Measurements at High Voltages and Low Power Factors*, by J. S. Carroll, T. F. Peterson and G. R. Stray, JOURNAL A. I. E. E., Oct. 1924, page 941.

Some Features and Improvements on the High-Voltage Wattmeter, by J. S. Carroll, JOURNAL A. I. E. E., Sept. 1925, page 943.

method—integration of the E-Q cyclograms—and the agreement is remarkably good.

As indicated by the theory and confirmed by experiment (Fig. 8), it is possible to reduce corona loss by setting up a suitable space charge around the conductor, for instance by enclosing it in a cylinder of a small diameter; it does not seem, however, that this method is suitable for practical applications; at least in the case of a transmission line. A radical reduction of the transmission frequency would result in a reduction of corona loss (Fig. 17), in addition to many other advantages, such as better regulation, etc.

POWER DISTRIBUTION AND TELEPHONE CIRCUITS—INDUCTIVE AND PHYSICAL RELATIONS

(TRUEBLOOD AND CONE)

SEATTLE, WASHINGTON, SEPTEMBER 18, 1925

H. S. Phelps: Messrs. Trueblood and Cone have very ably and clearly pointed out the importance of the type of power-distribution system in the matter of inductive coordination. This importance is recognized, and as the problem is better understood, more and more attention is being given it. It seems to me, however, that they have not placed sufficient stress upon another equally important feature—namely, the characteristics of the telephone system.

The ideal arrangement, of course, would be, first, a power system without residual currents or voltages, with the conductors very close together. Such a system would be closely approached by using multi-conductor cable, where all the current was forced to return in the conductors; second, a telephone system without any impedance unbalance in the metallic circuit or admittance unbalance between the two sides of the circuit to ground. In this desirable telephone system the subscribers set should not require utilization of an unbalanced ground connection for ringing. Connecting such an instrument to the system by means of a well designed and carefully installed cable circuit to a well balanced central-office cord circuit would likewise materially improve the situation.

An ideal power system would not produce longitudinal voltage in neighboring telephone circuits, and therefore could not cause noise in the telephone system, regardless of telephone circuit unbalances. On the other hand, an ideal telephone plant would not be susceptible to induced longitudinal voltages, and therefore could not be affected by any distribution system during normal or abnormal conditions, unless the induced voltages were of a magnitude to constitute danger to life or property.

Since neither ideal system is necessary or practical, it remains to determine how far either system may depart from the ideal without placing serious limitations and burden on the other. In order to ascertain the technical facts underlying this problem, the joint Development and Research Committee of the National Electric Light Association and American Telephone and Telegraph Company has been carrying on work under one of its projects at Minneapolis for over a year.

Although many interesting and useful results have been obtained, it would be premature to attempt outlining any of these at this time. However, it is expected that an interim report will be issued in the early spring covering the major findings of this work.

The considerations outlined for coordination of the telephone circuits with a distribution system apply in the same manner to the problem of induction from a lighting system discussed in the paper by R. G. McCurdy.[1]

P. D. Jennings: I gather from reading this paper and from an informal talk with Mr. Cone that the residual higher harmonic currents are the ones that give the most trouble. I should like to ask why resonance shielding on substation ground circuits might not take care of most of this trouble. As an example, suppose in a particular substation, our oscillograph records show that the ninth and fifteenth harmonics are predominant. It occurred to me that a resonant shield might be used to resonate out the ninth and the fifteenth harmonics on the substation ground and in that way eliminate most of the trouble.

A. A. Williamson: Mr. Cone referred to the relatively greater freedom from inductive interference that is usually experienced when both the power and the telephone circuits are in cable. Cases sometimes arise, however, where interference is experienced between the two classes of circuits when they are both in cable, and such cases are usually of somewhat more than ordinary interest. A very brief reference is made to such a case in the paper and it seems to me that a few words of additional description of the conditions in that case would be interesting.

In this instance, power at 13,000 volts was supplied directly by a three-phase generator, connected in Y and with the neutral grounded, to two open-wire circuits, branching and each supplying 13,000-volt power to a substation. The power company decided to provide a tie between the two substations and concluded that in this case the tie should be of cable. The tie when installed was approximately 1.65 mi. in aerial cable, and about 0.7 mi. in underground cable. The sheath of the underground cable was, of course, well grounded, but was not connected in any way to the neutral of the generators. This cable tie paralleled in its aerial portion an aerial telephone cable.

As soon as the tie was energized, interference was noted in the telephone circuits. An investigation showed that the sheath of the aerial power cable was also grounded at intervals with driven grounds but that these grounds were of rather high resistance so that the residual charging current flowing into the cable sought ground and returned to the generating station through the low-resistance ground afforded by the sheath of the underground portion of the cable. Thus the charging current flowed through the parallel as residual current and produced interference. By installing a low-resistance ground on the sheath of the aerial portion of the power cable, at the end more remote from the underground portion, the induction was very greatly reduced. The reason for this was that with the additional ground in place, the charging current flowed through the capacity of the wires to the sheath and back over the sheath. Thus, in each part of the parallel, there was a return path for the charging current flowing out over the three-phase wires and instead of acting as a residual current, it became a balanced component. This case illustrates the effect of residual current in causing induction sometimes of serious magnitude even when both classes of circuit are in cable.

I should like also to cite very briefly a case with which I happen to have had intimate contact on the Atlantic Seaboard. This case illustrates the importance on the induction problem of unbalanced load current flowing in the ground. In this instance, a 4000-volt, three-phase, four-wire distribution system with the neutral grounded at the point of supply, paralleled in open-wire construction an aerial telephone cable. The parallel was about 8000 ft. in length; it was joint construction and at the end of the parallel more remote from the point of supply to the power system, the three-phase, four-wire circuit entered underground power cable. At that point, the neutral wire of the three-phase, four-wire system was connected to the underground cable sheath. As the sheath of the underground cable was well grounded, it could be seen that any current in the neutral due to unbalance of load between the three phases would return to the power station both by way of the neutral and by way of the ground, the division of current in the two paths being in approximately inverse proportion to the impedance of these two paths.

In this case, measurements were made of the interference on party line subscribers' circuits in the telephone cable, and approximately 900 standard noise units were found at the subscribers' receivers. Owing to the excellent cooperation of the

1. Induction from Street-Lighting Circuits, by R. G. McCurdy, A.I.E.E. JOURNAL, Vol. XLIV, October, 1925, p. 1088.

power company in this case, it was possible during the investigation to disconnect temporarily the power cable from the aerial portion. When this was done, the path for the unbalanced load current to return through the ground, no longer existed. Under this condition the induction was reduced to about one-third of its former value.

This case seems to illustrate very well the effect of unbalanced load current when it can return through the ground. The use of power cable with the sheath connected to the neutral wire is only one of the ways in which a path may be provided for unbalanced load current to return through the ground. Whenever the neutral wire of a three-phase four-wire system is grounded at several points, this same opportunity exists and experience has indicated that it is usually one of the most important features from an induction standpoint.

K. L. Wilkinson: In practically all cases telephone subscribers are users of electric light and power service. Therefore, the companies, in order to serve these customers in distribution areas, must of necessity have their overhead lines in close proximity to each other. The problems arising therefrom are mutual ones since they involve the rendering of both services to these common customers in a safe, adequate and economical manner. It seems to be now generally appreciated that these problems require cooperative consideration by the two utilities in order to be successfully solved. The advantages of this cooperative treatment have generally been recognized throughout the country, and the splendid cooperation between the operating utilities in the field is producing most satisfactory results.

Now, in order that these individual efforts in the field may be most successful, it is desirable that all parts of the country know what is going on in all other parts of the country and be in a position to have made available to them all of the data and information which would shed any useful light on the problem. To this end, some four years ago there was organized the Joint General Committee of the National Electric Light Association, and the Bell Telephone System. This Committee was to investigate the physical relations between electric supply lines and communication lines, and to develop principles and practises for the guidance of the operating companies in solving their day-by-day problems.

The Joint General Committee has at its disposal all the operating experience of the country and has, as you know, published *Principles and Practises for Inductive Coordination of Supply and Communication Systems.*

The principles which have been developed are nothing new; they are based on the operating experience in their day-by-day work in coordination of the two systems.

One of the most important, I think, is the principle of cooperation and the advance notice. I thought of that particularly when Mr. Heinze mentioned the growth and development of the power systems in the distribution areas, the increasing load density and of the fact that nearly everybody now has a telephone, and every telephone must be a part of a system that operates throughout the United States, so that any one telephone in any one part of the country can be connected with any other telephone in the system.

If we are going to have the best and most economical power system to supply the people with electric light and power, and if we are to achieve the ideal of universal communication throughout the country, it is absolutely essential that locally and nationally we establish and maintain the closest contact between the two utilities in order that the public may obtain the fullest benefits of all of our engineering knowledge and experience.

The Joint General Committee, in approaching the problem, established one thing clearly and that was that each party should be the judge of his own service requirements and what was necessary to serve his customers. Next to that was the duty of coordination; that is, each party should so conduct his business as to be less productive of adverse influence on the other system; and, the system should be as free as practicable from things which would make it capable of being adversely affected.

I think that if we bear these major thoughts in mind,—first, that each is the judge of his own service requirements, and second, that we have a mutual duty toward the public to see that they get safe, adequate and economical service,—then the necessity of planning well in advance so that the situation does not get out of hand will be fully appreciated and we shall be promoting the best interests of the public in getting these two necessary services.

F. O. McMillan: Would it not be advisable to include in this paper under the three-phase transformer connections, some reference to both the primary and secondary winding connections, because of the fact that the third-harmonic magnetizing current and all multiples of the third harmonic in Y-delta-connected transformers are very nicely cared for when the delta connection is used on either side of the transformer?

S. B. Hood: In the paper I note, in the tabulation of the relative ease of coordination of the different systems, that almost without exception, the power system which is easiest to coordinate is the very system which the power man does not want to use.

Now that means that we must have a cooperative spirit of give and take. At some place in the list is the system which is just as good for the telephone man as for the power man. Just where it is, I don't know. I don't think it has ever been discovered, but we certainly have to work in a true cooperative spirit toward that end.

M. T. Crawford: Mr. Cone refers to the possibility of a slight ground which persists for some length of time as being a very serious source of interference when it occurs on the primary system.

I believe that practical experience will bear me out that on a grounded-neutral primary system it is almost impossible for a slight ground to persist for any great length of time. The ground on the grounded-neutral system is a short circuit and very soon develops into something that will trip the switch out. That would be an argument in favor of the grounded-neutral system as being superior from the point of telephone interference.

I should like to ask Mr. Cone what he considers the principal objection to raising somewhat the 5000-volt limitation which is at present observed in connection with joint-pole construction of light-and-power and communication circuits. This, of course, is an old question, but it seems today to assume a new aspect inasmuch as there is here evident such a willingness to cooperate. Perhaps the difficulties of joint-pole construction on voltages over 5000 have been where the distribution work of the light and power companies was not planned far enough in advance to take into account the telephone company problem.

The Puget Sound Power and Light Company now operates on a part of its system a commercial telephone system, which was taken over in connection with the purchase of a smaller company. On this system we have 6600-volt primary distribution on our own poles in combination with our own telephone service lines. We have been able to live very well with ourselves under such conditions.

L. J. Corbett: I wish to second Mr. Hood's remarks in regard to cooperation in spite of the suggestion which has been made that a wave of propaganda is upon us.

I have observed that the telephone men have studied the theoretical part of power transmission and distribution rather thoroughly. But very few power men study the telephone problems thoroughly. If we did and suggested to the telephone companies how to operate their systems, it might be taken in the same spirit as that in which the power men receive suggestions from the telephone men as to how they might operate their systems.

The ideal manner of handling the inductive-coordination problem would be realized if the same interests owned both the communication system and the power system. If this were true

they would be compelled to get together and determine the accurate economic solution in each case.

In California we act under the California Railroad Commission. The order of the commission is a state law, and under that law we are "required to cooperate." We find that this cooperation really works both ways. It is not always merely doing that which is requested by the telephone company; we do a little telephone engineering ourselves, although not in a very aggressive way. When the telephone company suggests coordinating measures, as a rule we put them in when it is possible without unreasonable expense.

If, from our standpoint, they do not appear reasonable, or if some construction or operating difficulty is involved, or a higher unjustifiable expense is indicated, we raise the question as to whether or not the benefits to be gained by these measures are worth the expense and trouble involved. When such communications reach telephone company officials, the requests are usually modified or dropped.

The beauty of the California law is that public interest comes first, and the cost of any of these coordinating measures is reflected in the rate. In this manner the public is the final unifying agent or manager and the holder of the purse-strings.

F. H. Mayer: Mr. Cone raised some objection to the grounding of the neutral return on 4-kv. distribution systems. It is the practise of the Southern California Edison Company to ground the neutral at numerous points throughout the distribution system to enable the secondary voltage to remain somewhere near a safe value should the return cable become broken. The driven pipes will tend to span the gap and thus prevent the Y connection from straightening out to a straight delta connection. If the loads on the different phases are carefully balanced there ought not be any communication disturbances.

H. M. Trueblood: I am sure we can all endorse the attitude expressed in Mr. Phelps' discussion, namely, that the solution of the problem consists essentially in finding the degree to which ideal systems must be approximated.

Mr. Phelps' reference to the joint investigation at Minneapolis should, I feel, include mention of the Northern States Power Company and the Northwestern Bell Telephone Company as participants. The progress which has been made in that work is due in no small degree to the effective cooperation and assistance of these two companies.

As regards the suggestion that the paper does not lay sufficient stress on the characteristics of the telephone system, I wish to say that there is no desire to ignore this phase of the problem. The paper has been presented as one of a group dealing with various aspects of power distribution and, as such, it does not purport to discuss telephone-system characteristics, except incidentally.

With reference to Mr. Jennings' inquiry, I know of at least one case in which the measure which I believe he has in mind was applied successfully. In this instance, there were two harmonics to be taken care of, the 15th and the 33rd, and two antiresonant elements, each consisting of a condenser and an inductance in parallel, tuned respectively to the frequencies of these two harmonics. They were connected in series between the neutral of a 13,000-volt generator and a grid resistance of low value, the other terminal of which was grounded. The exposure involved was about 3 mi. long at a separation of some 30 ft. I have been informed that effective reductions were obtained in the noise, previously quite severe, and that the arrangement has proved satisfactory from a power-operating standpoint.

Mr. McMillan refers to the omission of reference to the effects of delta windings. Because of the rather extensive ground covered in Table I, it was necessary to simplify the table and to make some selection among the different features that might be included. Of course, delta windings on transformers do affect the magnitudes of the triple-harmonic voltages and currents that appear on the lines; but this effect may be either to increase or to diminish the magnitudes of the line residuals of these frequencies, depending upon the locations of the transformers concerned and the conditions of grounding. Of the systems summarized in the table, those presenting the greatest difficulties in coordination are ones in which the load currents are more important than excitation currents, and, of course, the transformer connections are immaterial, so far as load currents are concerned.

Mr. Hood and others have remarked that the distribution systems classified in the paper as presenting the greatest facility of coordination are not those which a power company would ordinarily adopt if nothing more than the distribution of power were involved. Without attempting to pass judgment on the relative merits of different systems from the latter standpoint, I believe we should not be surprised that a conflict of this character is found to exist. This is an essential feature of the situation with which we are confronted at the present time. In fact, we have an inductive-coordination problem largely because types of systems which are deemed advantageous from one standpoint may not be so from the other. Mr. Hood's inference from the situation to which he refers is substantially the same as that arrived at by Mr. Phelps, and I find no difficulty in concurring in it.

Mr. Hood has referred to the use of multiple grounds on the neutral as a stabilization proposition. While stabilization may be the principal purpose in using the multiple-grounded neutral, it is unfortunately true that this does not prevent the setting up of residual load currents.

In his remarks applying to Mr. McCurdy's paper, as well as to that by Mr. Cone and myself, Mr. Heinze refers to the question of cooperation between the telephone company and the other electric utilities. It is true that most telephone engineers who have had to do with the inductive-coordination problem keep prominently before them the idea of cooperation. That is because it appears to us that no other method of approach can be successful. While this is more nearly self-evident now than it was some years ago, it is so important that one feels justified in laying stress upon the idea. The same thought has been expressed more than once by power engineers in the discussion of these papers.

Mr. Heinze asks how far the telephone company will go in this cooperative endeavor. As to the general spirit and attitude of the Bell System, I will merely remind you that for a number of years it has gone to considerable trouble and expense to adapt itself to circumstances which have arisen because of situations of proximity between its circuits and power circuits. That this willingness to cooperate in the fullest way will be maintained in the future seems to be sufficiently evidenced by the adoption of principles and practises by the Bell System and the N. E. L. A., under which cases are now being handled generally throughout the country, and by the undertaking of a joint research investigation to determine the fundamental physical and engineering factors which enter into the inductive-coordination problem. The work at Minneapolis is one project in this general research program, and other projects are under way in different parts of the country. As to division of cost, it must be recognized that after the correct engineering solution of a given case has been found, the question of an equitable division of the expenditure necessary to put it into effect will arise. This phase of the problem has so many ramifications that any attempt to summarize it here might be misleading, and a comprehensive discussion would carry us much beyond the field with which the paper is concerned.

In conclusion, I wish to make it clear that Mr. Cone and myself have attempted nothing more than to analyze the problem in a preliminary way without going into detail, and to bring out the technical facts known to us as we see them. Mr. McCurdy, I am sure, would agree with this attitude.

D. I. Cone: Mr. Crawford spoke of the interference that arises from accidental grounding of one phase wire. On a three-wire system normally isolated from ground, such conditions may

persist for days at a time, or longer. This can be prevented by suitable maintenance measures. On the other hand with the grounded-neutral system the tendency is for such accidental contacts to develop into short circuits and to operate the circuit breakers. From the discussion by Messrs. Crawford and Cunningham it is evident that the local conditions immediately surrounding an accidental ground contact cause great variations in contact resistance and resulting ground current.

Mr. Crawford has raised the question of joint use at higher voltages than has been customary in the past. Many of you are doubtless aware that the subject of conditions of joint use is under active study by the Joint General Committee of the N. E. L. A. and the Bell Telephone System. We do, of course, recognize that there are some special cases where joint use of poles at higher voltages is the best engineering solution to meet the conditions of a particular problem and in such cases joint use is being approved.

Mr. Crawford also stated that his company had lately acquired a combination power and telephone distribution system with the power lines operating at 6600 volts. Our experience has not been encouraging as to the conditions of noise and hazard that obtain in such circumstances.

There are, of course, differences of opinion in respect to the question of protection from the hazards of power distribution. I wish to suggest, first, that higher voltages are ordinarily employed in distribution for longer distances and larger loads and, second, that this inevitably means either extraordinary measures to prevent hazard and impairment of service or else lowered standards. It is our view that advance planning will enable us to avoid to a great extent the necessity of joint use at the higher voltages. Meanwhile, any specific situation that arises we are more than ready to consider.

Mr. Corbett has described the working out of cooperative consideration of specific cases in California. As he states, the best results are obtained when the reactions of proposed measures are thoroughly considered by both parties. Suggestions arising from the study of these problems by the power engineers are cordially welcomed. I think it fair to say that the working together in California is not merely a matter of compliance with regulations but a realization that it is the rational way for the power and communication utilities to solve these problems. Mr. Mayer's discussion brings out the fact that there are conflicts to be adjusted between the requirements of the communication and power distributions and that the degree of detriment from multiple grounding depends upon several factors in the layout of the systems. Mr. Mayer's point about the use of multiple grounds on the primary neutral for stabilization has also been brought out by Mr. Hood. While recognizing that accurate balance of loads might prevent detrimental induction in communication circuits so long as all phases are present, we must not overlook the facts that setting up and continuously maintaining such close balance is not a simple matter and that exposures often occur where only one- or two-phase wires are involved.

OPPORTUNITIES AND PROBLEMS IN THE ELECTRIC DISTRIBUTION SYSTEM[1]

(Blake)

Seattle, Washington, September 18, 1925

C. E. Carey: I wish to discuss one or two details in Mr. Blake's paper. He mentions primarily the single-pole protective unit. He goes into detail and attempts to establish the justification of the multiplicity of parts. However, the question of single-phase or single-pole units cannot be separated from the whole network. Personally, I believe that the multiple unit is the real solution. We have seen that there are certain state laws requiring that we open the entire circuit, rather than allow an unbalance on the networks and produce inductive interference. It is much better, I believe, to clear the entire trouble as quickly as possible rather than take out one phase at a time. The three-pole unit will not occupy as much space in the manhole as three single-pole units. The automatic a-c. network protector is a device which does everything you can expect it to do. It is designed to go into the standard 35-in. manhole cover. The covers of the units are of aluminum, are light and can be handled by one man. Furthermore, if inspection is to be made of these devices the time consumed will be less with three-pole units than with three single-pole units.

In regard to the translator, I believe, that anything we put in to complicate the network is defeating the purpose of the a-c. system. The whole thing resolves itself back into continuity of service, simplicity and low cost, and the only way we can arrive at that service with a reasonable cost is to trim it down to just the bare necessities.

Practically everyone will agree that if we had it to do over again, we would never put in a d-c. network. We have it, but what are we going to do with it? If we attempt to change to an a-c. network we are confronted with the cost of changing over the customer's equipment, which will be so high in some cases that the interest and other fixed charges on that additional cost will more than carry the high losses in the d-c. network. However, one solution is being used to bring the economics of the d-c. very close to those of the a-c. network, the use of the automatic substation. The automatic substation gives primarily the same type of distribution as the a-c. system; that is, high voltages to the converting stations and low-voltage for distribution. The automatic substation is reliable and economical. A real analysis of the problem will often show that it is better to hold to the d-c. network, remove the concentrated manually operated stations, and distribute that conversion power over a network to a large number of small conversion stations, approaching extremely close to the transformers on the a-c. network in losses and other factors which come into the distribution problem.

Henry Richter: In considering a-c. secondary networks, it is well to recognize that the network systems mentioned by the United Electric Light and Power Co. as used in New York City—and also those in New Orleans—use triple-pole automatic network units exclusively, and that similar systems and network units will shortly be in operation in Dallas, Memphis, Knoxville, and Atlanta. Minneapolis will install these units as the load grows, preparatory to forming a network. These comprise all the companies that have completed or started to construct a network like that of Fig. 2, using automatic network units.

In practically none of the installations in these cities, where space might permit single-pole units to be installed, has it been necessary to add to the dimensions of new manholes in order to accommodate the triple-pole network unit; or to construct new manholes, or enlarge old ones, due to any extra space required because single-pole units were not available; or even to take up space in an existing vault that could be ill spared. These networks are considered justifiable only in heavily loaded areas where the loads are too great to be supplied in the single-phase manner. Three-phase transformer banks are therefore the rule, ranging in size from three 25-kv-a. single-phase transformers up to three 100-kv-a. transformers. The manholes and building vaults to accommodate such banks, to allow for growth of load, to ensure no excessive temperatures, and to permit proper racking and maintenance of cables, must be of such size that there is no lack of wall space for a triple-pole network unit. It is customary to locate this unit on the wall opposite that along which the three transformers are placed, and close to a corner of the manhole. In existing manholes having three-phase banks formerly part of a radial primary and secondary system, the triple-pole network units can usually

1. Abridged in A. I. E. E. Journal, December, 1925, p. 1355. Complete copies in pamphlet form only.

be put into the space formerly occupied by the large secondary junction boxes. In most cases, this space is not otherwise useful, for the network systems employing these automatic network units are so simple that nothing else is necessary in the manhole besides the transformers with or without small reactors, the cables and the network unit. Further, it is an erroneous idea that single-pole network units, particularly in a submersible housing, can be made so tiny that they can be installed in any odd corners of a manhole. The desirability of giving them proper maintenance makes such procedure far from advisable even if they were so small.

If it is desired to have the leads to the secondary mains leave the triple-pole network unit horizontally, to either side, it is extremely simple to provide a small terminal box where the outgoing leads emerge from the top of the submersible housing. This small box can have wiping nipples mounted horizontally at either side. The extra bend in the cable is thus eliminated. However, in none of the cities enumerated has this been necessary. Seven and a half feet is an average height for these transformer manholes as determined by good subway construction practise and even with a triple-pole network unit for a bank of three 100-kv-a. transformers there is no cramping of cables entering and leaving the housing.

When the triple-pole network unit was being designed, it was recognized that the submersible housing must pass through a certain minimum-size manhole opening. A country-wide survey was made and it was learned that the great majority of companies have adopted 35-in. diameter round as the smallest opening for transformer manholes in existing or contemplated construction. Apparently this minimum was governed by the dimensions of 100-kv-a. single-phase subway transformers. Accordingly the triple-pole units of all sizes were designed to pass through a 35 in. diameter round opening. In none of the six network cities mentioned, and together they are typical of all other cities, will it be necessary to rebuild the opening of any manhole to permit the unit to pass through; and careful investigation shows that in none of the cities where three-phase networks are being considered for the future will there be any difficulty in this regard.

If it becomes necessary to rack cables along the wall back of the network unit, it is just as easy to mount the triple-pole unit on a pipe framework braced to the wall as for the single-pole unit, since the two types are not very different in depth. However, just as with junction boxes, subway oil-circuit breakers and such apparatus, electric service companies do not consider this good practise in manholes. In only one case has a company mounted on a transformer tank a piece of auxiliary apparatus of such size as a single-pole network unit might be, and there the conditions are unlike those anywhere else in the country. In general, the place for such equipment is against a wall.

Where subsurface conditions make it impossible to build a manhole for three transformers at any particular location in the street on a main thoroughfare, three solutions have been found to be applicable: (1) obtain a vault in the basement of a building; (2) install a manhole under the sidewalk, or (3) locate the manhole in the street as close to the desired location as possible. In almost no case has it been impossible to use one of these methods. Where the third method must be employed, the distance from the most desirable location is usually so short that the cost of the extra length of duct line is small compared with the extra cost of three smaller manholes over one larger one. It is also doubtful whether city authorities will permit subsurface obstruction at three neighboring points.

The triple-pole network unit for manholes is constructed with a window of heavy, wired glass, amply strong, in the cover; this makes inspection of the principle parts easier than by taking off the cover of a single-pole unit. If it is necessary to get at the parts inside, the time to remove the few extra bolts or lugs holding the cover on the triple-pole unit is negligible. The aluminum cover of the triple pole unit can be handled by one man without difficulty.

The design of the single-pole unit to permit easy removal of the panel from the housing when it is desired to make repairs at the shop follows the identical idea that is incorporated in the triple-pole network unit design. Similarly, right from the start, fuses have been installed on the panel of the triple-pole unit, in series with the outgoing leads, to make a separate fuse box unnecessary. These last two points, therefore, do not apply exclusively to single-pole units.

The paper claims that the single-pole unit conforms with the method of single-pole switching inherited from the radial system of distribution. In a properly designed three-phase network system single-pole switching is no longer necessary and may be abandoned. In a radial system it is better to have some light than no light, when trouble occurs on a feeder, and hence the value of single-pole switching. Networks are designed so that in no case will trouble on any feeder cause interruption of any service fed from the secondary network. Among such troubles there must always be included the putting out of service of all three conductors of a feeder, either by phase-to-phase short circuit in a three-conductor cable, or, where three single-conductor primary cables are in the same duct, by the melting down of all the conductors by a severe fault to ground on one of them. It may even be necessary to provide for the possibility of a manhole fire taking two feeders out of service simultaneously. Thus, there is no necessity in complicating the system to get the insurance that goes with keeping two of the phases in service when the third goes out. One large company even plans to use three-phase regulators on three-phase feeders serving an important network, and some are thinking of using triple-pole oil-circuit breakers at the station and three-phase distribution transformers where these can be passed through the existing manhole openings.

The paper overemphasizes the importance of manhole installations. While the difficult conditions encountered in manholes must be met and are being met, it should be remembered that of a total of over 600 triple-pole network units that will be in operation by the end of this year, less than one third will be in manholes.

Three single-pole units have three operating mechanisms in place of one for the triple-pole unit, and this means more parts to maintain. Three units together have more surface to gasket than a triple-pole unit, which gives more chance for water to leak in with any given type of construction. Three units also occupy a greater total space in the manhole, and every cubic foot is valuable. When the design of automatic network units was first under consideration, all these factors were weighed and the single-pole type was abandoned as inferior to the triple-pole type.

The simplest method of ensuring stable operation of regulators on feeders operating in parallel on a network[2] does not require any extra apparatus such as the transformers T and reactors X of Fig. 3. It employs only a transfer switch, corresponding to switch S for each feeder. This scheme was given a thorough test on the network system of the United Electric Light and Power Company, where it originated, and was shown to be entirely satisfactory.

One of the greatest problems in connection with secondary networks is the type of combined light and power secondary system to employ. Mr. Parker has blazed the trail in an effort to devise some scheme whereby the advantages of the combined system may be obtained and the disadvantages of the star connection avoided. It cannot be too strongly urged that others follow in his steps. However, it must be pointed out that the translator scheme may introduce disadvantages that outweigh those of the simple four-wire, star system, and these

2. Described in the *Electric Journal*, July, 1925.

disadvantages may so handicap the development of the network idea as to result in a loss to all concerned.

In the star system of Fig. 4 the only voltage unbalance at the motor terminals is caused by unbalance of load in the secondary mains due to varying sizes of the loads as encountered along the street. This unbalance may be reduced to a negligible amount by care in connecting two-wire and three-wire services on alternate phases. From the analysis of the translator scheme it is evident that it may easily result in voltage unbalances of at least 10 per cent at the motor terminals. For the same per cent voltage unbalance on a motor as per cent voltage reduction, both the heating and starting torque are affected to a worse degree in the case of the unbalance. Hence the effect on motors would be worse with the translator scheme than by operating them at 199 volts on a 115/199-volt star-connected secondary.

Adding extra transformers on other phases to obtain a better balance of voltage where power loads are frequent not only increases the number of transformers on the system, but also calls for larger or more manholes to house them. This would materially cut down the savings in transformer capacity gained by the diversity that networking makes possible.

Where the 115/199-volt star-connected secondary system is employed it has been necessary to use auto-transformers on not more than 15 to 20 per cent of the motors connected to the system in order to supply satisfactory voltage. On the basis of power load equal to half the lighting load these auto-transformers represent less than 7 per cent of the capacity of the secondary system. If the translators, equivalent in capacity to the total capacity of the secondary system, cause an increase of investment averaging 10 per cent of the entire distribution system cost, the auto-transformers necessary to ensure satisfactory operation of motors on a star system involve an increase in investment of less than 0.7 per cent.

The unbalance of current for the case of power load half the lighting load requires that the wire carrying the maximum current in the translator system use about 60 per cent more copper than for the star system. It would be highly inadvisable to proportion the size of the three-phase wires in the translator scheme according to the loads in those wires, because the sizes would have to be changed from block to block all over the system, and this would complicate the system even more than by adding the translators. Hence all secondary wires would be as heavy as the largest one, and this might mean a 60 per cent increase in the total amount of secondary copper required. Where 500,000-cir. mil copper is taken as the largest size, the extra copper would in many cases require a second main and duct. To these extra costs must be added those of the translators, value of manhole space they would occupy, and losses in secondaries and translators. Even the seven-wire, separate-light-and-power secondary system would not cost more and would be simpler. The increase in cost due to all these items might easily overcome any saving gained by combining power and light mains and defeat the very purpose of the translator scheme.

If the electric service companies want to inconvenience the fewest number of customers using a star-connected system, they will adopt the 115/199-volt three-phase system, as only the polyphase motor users will be affected. In the few cases where tests show insufficient voltage, the simple auto-transformers can be employed to boost the voltage. In Memphis, a 115/199-volt system of this kind has been in operation for over ten years and the customers are entirely satisfied. In Rochester, for several years, light and power loads in large buildings downtown have been supplied by 120/208-volt transformer banks in the basements and, even though motors up to 40 h. p. are connected at the end of long risers and no auto-transformers are employed, the customers praise the service.

It must be recognized that for most systems an a-c. network system, even though fed at 13,200 volts is just a little less than half the annual cost of a d-c. system and hardly less than 80 per cent of the cost of an a-c. radial system. These ratios have been checked independently by the engineers of five large systems. Hence, we would be deceiving ourselves as to the economic value of the translator scheme for it introduces such elements of additional cost as would wipe out the balance now in favor of a-c. networks.

The control of multiple street lamps or pole-mounting, constant-current transformers supplying series street lamps, by means of carrier current over the primary feeders, will represent a great step ahead. One company has tried out such a system, but the operation has been faulty and the relay units on the poles are of such nature as to be relatively expensive. The sender at the substation is also complicated. Another company has developed a simpler form of relay unit, and tests of a number of these, equivalent to at least a full year's service, have proved them satisfactory. This relay unit is compact, substantial and inexpensive. The sender unit is also simple and strongly built.

M. T. Crawford: Mr. Blake's paper refers to a method shown in Fig. 5 of which the title is "New Connection of Induction Regulator Circuits to Eliminate Circulating Currents." I think I am correct in stating this connection has been used recently by our company in our new Union Street substation and has proved very successful in regulating 4500-volt feeders in a multiple-feed network. One practical point in connection with it has been that some means has been found desirable to automatically disconnect the regulator control circuit on low voltage, so that regulators will not assume, during system trouble, different positions after fluctuations. I mean by that if a short circuit comes on the transmission network, and the voltage of the system as a whole oscillates back and forth, perhaps reaching very low values for brief moments, there is a tendency for the regulators to attempt to follow these voltage variations up and down. By the time matters have settled down again, some of the regulators are in one position and some in another, due to their slightly different characteristics. That has resulted at times in tripping out of network switches on the underground distribution system due to reverse flow of power for brief periods from one feeder into another where the voltage conditions were slightly different. By the simple expedient of providing a low-voltage release on the regulator control circuit, this trouble has been eliminated. The operator at the substation can reset the control circuit after the system has quieted down to normal.

The translator referred to is a very clever development. The Puget Sound Power and Light Company's underground distribution system employs single-phase, three-wire mains for lighting and alternate blocks with longitudinal alleys are placed on alternate phases, so the first alley is on one phase, the second alley on another, and so on. By that method the phases are relatively well balanced at the substation. In places, we have recently installed a fourth wire paralleling the single-phase, three-phase mains to provide small polyphase service. The result has been three-phase, four-wire mains in each alley similar to the ones referred to by Mr. Blake, and the respective alleys in the same phase relation as those shown in his diagram.

The translator, therefore, in our case offers something to look forward to as a possibility of permitting interconnection of the three sets of secondary mains for purposes of phase balancing or load protection if it should be found desirable. However, the addition of apparatus is always to be very closely scrutinized, and its necessity must be proven before it is added, as the simpler a system is, the better the service will always be.

A. H. Kehoe (communicated after adjournment): Regarding Mr. Blake's discussion of single-pole versus three-pole a-c. subway network switches I consider the proper switch to use is the one which will give minimum cost over an extended period. The cost of revising a few existing locations will be negligible on the total installation cost. Tripping and closing

elements in these switches represent a major item of cost and single-pole units will nearly triple this cost for each installation. Space, that is, cubical contents, naturally will be less in a three-pole unit than in three single units. These conditions seem to make the three-pole unit the one to be adopted generally. However, I do not favor certain of the existing three-pole switches of the so-called "battleship" construction. If the principal installation advantages set up by Mr. Blake for single-pole switches be used as specifications for three-pole switches, none of the latter's many advantages need be considered except the greatly reduced cost.

Under operating advantages there are several references to separating the phases either in the physical location or for operation of the transformers. I believe this is a case of confusing what *can* be done with what *is likely* to be done. It is possible to separate phases in three transformer vaults but it is probable that one vault three times as long will be cheaper and better if polyphase load is to be supplied. The system of polyphase secondary distribution is primarily for better universal utilization of electric service, as methods of balancing are now successful without it. However, that balanced polyphase loads are desirable at all points on a system, is a design axiom. All progress up to this time points to polyphase rather than single-phase distribution transformers for ultimate use. If the standard three-wire, single-phase system is taken as analogous to the polyphase system, it is evident that two single-phase, two-wire transformers could be placed in separate transformer vaults supplying a three-wire system. This is not likely to be found, however, in standard practise as all the capacity is found in one unit and a vault is built to take this larger unit, as this design gives minimum cost. I believe similar conditions will hold as the polyphase system develops.

Concerning the operating situation with radial distribution, the single-pole substation switches had economical advantages which could be charged to reliability. Since, in network distribution, there must be, and is always, sufficient reserve on each phase to allow for a failure of that phase, in each locality where it exists it is certain that the remaining phases will have sufficient reserve capacity to be eliminated in case of fault. Such operation does not have any effect upon service which can be equated against the increased cost, when the money, if necessary, could be expended to obtain an increased reserve upon all phases so that the particular phase in trouble would benefit by having a greater reserve. I doubt whether single-pole network switches are proper even with those systems already operating with three single-pole switches on four-wire, 4000-volt service, as new load will cause a higher voltage supply to be used than 4000 volts. It is possible to superimpose the new load on to the existing system and avoid the double transformation which is otherwise required.

Mr. Blake describes a method of cross-current compensation as the "most promising." It is, however, neither simpler nor easier of installation than others now in use. The several such connections should be given consideration before applying a definite arrangement to a particular system. The method described makes constant current and power factor the major considerations, while constant service voltage becomes a secondary one. Constant and correct service voltage is one of the most important elements in the business. While the network insures reliability and better voltage regulation than on radial systems yet this latter should not be compromised unnecessarily. It seems to me to be preferable to design the system for proper balance of load and have the regulating equipment give proper voltage under all conditions. The connection proposed does the opposite. Applying such a connection to a number of long feeders on an extended network makes other connections preferable due to the voltage variation under the ordinary load shifting.

It should be noted that a distribution network does not simulate a bus in respect to voltage or to concentration of load as indicated in Fig. 3 of the paper.

I fail to find in the translator description any reference to the use of this connection on certain distribution transformer secondaries to join and supply the different mains. If such a device ever has a practical application I believe it will be necessary to make it up in such a form, rather than as an auto-transformer, owing to cost and losses involved. Mr. Blake's statement that each section of secondary mains on a Y-connected system is not likely to be well balanced is not in accord with the purpose of adopting polyphase distribution. In some existing installations a certain amount of unbalance may exist due to the utilization having been designed for three-wire, single-phase service, but new installations are easily balanced and it is only in districts where growth of loads occur that any considerable amount of three-phase, four-wire mains are likely to be installed.

D. K. Blake: Mr. Carey questions the application of the single-pole switch. Mr. Richter's discussion also differed as to the application of the single-pole switch. It is recognized that the objection to the multiplicity of units for maintenance is valid. It is also recognized that a number of large companies will be able to utilize building and sidewalk space and, therefore, for these places the triple-pole switch is preferable. In the synopsis of the paper is this statement: "The circumstances which make single-pole switching preferable are outlined." It was my impression that there was a similar statement in the text, but on reading it over I notice there is not, and, therefore, some wrong conclusions might be drawn because of this omission. In his discussion Mr. Richter seemed to deny that these circumstances exist at all. He mentioned the cities where the large switches are being used. I agree with him that the triple-pole switch is preferable in these cities with one exception. Mr. Richter's references to the design of the switches indicates he misunderstood the paper. No exclusive features are claimed. To include all of these features in a triple-pole switch presents serious difficulties which are expensive to overcome. The operating advantages of single-pole switching may be questionable. Some engineers believe it desirable.

Mr. Richter mentions that the transfer switch shown in the *Electric Journal*, July 1925, corresponds to switch *S* shown in Fig. 3 of my paper. Switch *S* is a single-pole auxiliary switch whereas the transfer switch consists of four auxiliary switches or else one auxiliary switch to control an electrically operated double-pole double-throw switch. The cross-connected scheme is not as simple in its operation. All regulators are not adjusted at the same time according to the amount of circulating current passing through them but adjustment is obtained in a sequence. Mr. Kehoe's statement that the proposed connection does not "give proper voltage under all conditions" is not clear to the author. The line-drop compensator in each feeder maintains constant voltage at the load center with varying load. The impedances of the feeders may be different, some feeders may be long and some short. The proposed connection, by substituting a phase shifter at *T*, can also be used with three-phase regulators which is not true of other connections now in use.

I want to thank Mr. Crawford for telling us of his experience with the new regulator connection. We shall have to learn something about the operation of this connection on the systems where we use the sensitive reverse-power relay. I am glad to learn that Mr. Crawford has found a simple way of correcting the trouble.

It is not evident to the author why the translator system "may easily result in voltage unbalances of at least 10 per cent at the motor terminals." The translator system is simply the tying together of four-wire combined light-and-power mains which are supplied by delta-connected transformers. The unbalance on these mains is due to the lighting load on one phase and since this is limited to 3 per cent regulation that is also the extent of the unbalance on a 230-volt circuit. Heavy power loads are usually supplied with individual transformer banks and, there-

fore, it is not evident why larger or more manholes are necessary for this purpose on the translator system.

The translator system may be used with single-conductor cable with two of the phase wires larger than the third—just as is done in radial practise. These sizes would not have to be changed from block to block but would be uniform over the system. The case of power load equaling half the lighting load required that the wire carrying the maximum current in the translator system use about 34 per cent more copper than for the star system instead of 60 per cent as given by Mr. Richter.

Mr. Kehoe refers to a scheme using transformer secondaries. Such a connection is shown in Fig. 1, herewith, utilizing four

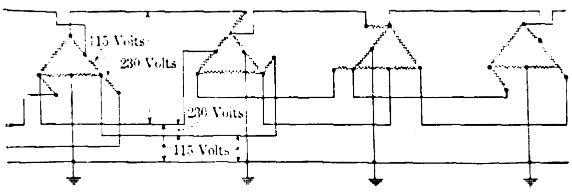

FIG. 1

standard distribution transformers. The main objection to this system is that it is tied up with the primary feeder making it necessary to provide two triple-pole network switches for protection. The translator is independent of the primary voltage. The fourth transformer is greater in kv-a. rating than the translator and very much more expensive in case of 13,200-volt or 11,000-volt primaries. The fourth transformer should be located in the same manhole with the other three while the translator may be located where convenient. Part of the lighting load is supplied from open-delta connections.

DISTRIBUTION TO SUPPLY INCREASING LOAD DENSITIES[1]

(CRAWFORD)

SEATTLE, WASHINGTON, SEPTEMBER 18, 1925

C. A. Heinze: Mr. Crawford assumes as an ultimate load density in his residential areas approximately 6250 kw. per sq. mi. He has used some figures that apply apparently to Seattle, which possibly may not apply to other cities. The number of houses per block, and the number of blocks per square mile—those are local conditions. The ratio of apartment houses and flats to single residences determines the load density for residential consumers. Studies of the conditions as they exist in Los Angeles show that it is reasonable to expect future load densities of 2500 kw. per sq. mi. for single residences, 6000 kw. per sq. mi. for flats and 19,000 kw. per sq. mi. for apartment houses. The actual load density in any square mile will be determined by the ratio between the different classes.

A few years ago the Commonwealth Edison Company of Chicago had already experienced in the Loop district a load density of 75,000 kw. per sq. mi., and was preparing for a future load density in this same area of 200,000 kw. per sq. mi.

The great majority of papers presented at this convention have to do with Y-connecting the present 2300-volt systems in order to get a higher feeder voltage. Personally I think that we are wrong in stopping at this voltage. We should go higher. While some authors have intimated in their papers that if they were to start over they would probably adopt higher voltages, it seems to me the sooner we adopt the highest practical voltage considering future load densities, the easier our future distribution problems are going to be. Certainly we do not want our systems growing larger and larger with the lower voltages, and then reach a time when we have to change to a higher voltage. Why not do the changing at the time when the system is small?

One thought that seemed to run through all the papers is that each of the authors in turn said he has a system plan. Certainly that is a big step in the right direction. The trouble in the old days was that we did not have a system plan.

Having a system plan, and realizing the enormous load densities of the future, we should build today that proportion of the ultimate plan which will give us maximum economies.

It should be realized that when a 2300-volt delta-connected system is Y-connected, we have then reached the ultimate change that can be made in that particular system. On the other hand, by adopting a higher delta voltage for the time being, we may then ultimately, when our load densities become heavier, Y-connect that and have a voltage suitable for the densities of that time.

R. E. Cunningham: I want to ask Mr. Crawford what happens when their primary phase wire falls on the ground. We have had some very serious and expensive accidents; our primary wires have fallen on the ground and lain there some time before we discovered them, and in the meantime caused troubles. To us, taking care of that feature and fully protecting the public is more important than possibly saving a little copper by using a common ground return.

Our state law requires that where the higher voltage lines such as 11-kv. and 15-kv. circuits are paralleling telephone toll lines and become grounded, we must discontinue the service until the ground is cleared. From the hazard to the public it has become a practise with us, even though it does not parallel a toll line, to pull off the circuit until the ground is cleared. On a delta-connected system we have ground detectors which will show us when our circuit is on the ground, but with a Y-connected system such as the 4-kv. we are still hunting for the answer. If Mr. Crawford could, I wish he would give us what his experience has been and what is the accepted practise of taking care of cases where the primary wire falls on the ground.

We have only recently begun the use of automatic reclosing switches having installed two smaller substations with such equipment on the 4-kv. outgoing lines. We arbitrarily adopted the practise of reclosing the first time after 2-sec. interval, the second time, 15 sec. and the third time 30 sec. If the short circuit still remains on the circuit, the switch then locks out. I would like to know what Mr. Crawford's practise is in that regard.

L. R. Gamble: I note that Mr. Crawford has planned his system somewhat in the way the telephone engineers have been planning their systems for the past several years. It always seemed to me that it was a very good scheme. However, very few companies today are doing that thing, planning for the future.

Regarding the matter of diversity in load, on distribution circuits, I note Mr. Crawford has arrived at 1600 watts per residence. In accordance with tests now being made by the National Electric Light Association, on the Electric Range Committee of which I am the engineer in charge of collecting all the data and making the reports, we have arrived at a similar figure on our more or less superficial tests. The 1600 watts per residence is on the basis of about 150 residences, and takes into account the diversity so that in considering a distribution network such as Mr. Crawford has considered here, the figure is probably fairly close. However, in radio systems, that figure is going to be somewhat higher as the diversity factor will be smaller for a smaller number of residences.

I have been more or less a dyed-in-the-wool radial fan. I have not particularly liked the network system. As time goes on, however, it seems that due to improvements in apparatus, and varied schemes in working out different problems in practise, the network system for the higher-density loads is the coming system. No doubt it is in underground systems, but in overhead systems, there seems to me to have been some sort of question.

There is one question I wanted to ask Mr. Crawford. In laying out his system for the future, he figures that he will not have

1. A. I. E. E. JOURNAL, October, 1925, p. 1063.

to rebuild or make any very material changes as the load grows. Considering this, does he use the butt-treated pole? Of course, I realize in asking this that not only does the butt of the pole decay in certain localities, but sometimes the top is also subject to rot.

There is one other point, and that is regarding trees. By the extension of the primaries to a considerable length and interlacing them as Mr. Crawford does, he is subjecting his line to tree interference which is very considerable. All distribution engineers and power men realize the disadvantage of trees, and, so long as we are going to have the "city-beautiful" idea, which luckily a great many cities have not yet adopted, our troubles will be ever increasing.

Digressing a little from Mr. Crawford's paper, there is one subject which should be of interest to distribution engineers and that is the painting of poles. An engineer is an artist to a certain extent; probably in the negative sense. The idea is that he should be able to put these poles in the streets and paint them such a color as to paint them out of the picture instead of into it. Of course, we don't all paint our poles. In some places it is required by ordinance. But I think we ought never to paint a pole a pea-green color.

F. H. Mayer: It has been found in designating electrical grounds for substations and power houses that it is more practical to ground non-current-carrying structures by means of a network, supplemented by one or two ground electrodes, than to ground the various structures by numerous electrodes.

A well designed grounding system must serve two general functions—

1. It must be designed so that its operator can come in contact with any non-current-carrying structure with safety at any time, and
2. It must permit of continuity of service.

The safety feature is accomplished by the metallic network, because a condition is approached similar to that of a station that is constructed on an immense metallic plate, thus tending to keep the potential gradient at the time of an electric failure to practically zero. The control of the potential gradient permits of the grounding of 220-kv. transformer neutrals and cases to the network with absolute safety to the operators.

The continuity of service is brought about by a more reliable relay performance and due to the fact that there is a low-resistance path from any part of the structure there is no tendency for high-voltage current to pass through the control board or other vital parts of the station.

So far as local failures are concerned the network suffices. However, if failures occur foreign to the station, the ground current returns to the station transformer neutrals through the earth and finally is picked up by the electrode that supplements the network, or if an overhead ground wire is used some of the current will return over it.

The overhead ground wire may not be essential where it is possible to extend the ground electrode into a stratum of permanent moisture and it is reasonably sure that the same stratum is again cut at the other stations. This is not always practical in rough areas, and in such cases the overhead ground wire serves a very good purpose, in that it furnishes a lower-resistance path than what is possible through the earth and ground electrode. Most of our power houses are located in mountainous country and such is our experience.

The point that can be gained, I think, is that on distribution systems feeding consumers in a hilly section, for the safety of human life, it is of prime importance, to furnish some reliable metallic return. This can be accomplished by grounding all transformer cases and neutrals to the water pipe or by conductors as outlined by Mr. Crawford.

It has been found that water pipes are not always reliable. Our experience showed in one instance that the pipe supplying the operator's cottage with gas was of lower resistance than the water system. In this particular case, the water system was connected to the transformer cases through the transformer-cooling system. The gas main was connected to the water main through the automatic water heater and at the time of an electrical failure on the 60-kv. switching rack the ground current that flowed through the water heater was sufficient to destroy the heater coil.

It may be possible that this water system also had insulated sections. At any rate, it only goes to show that water-pipe grounds are not always reliable.

M. T. Crawford: I have been very much pleased at the evident appreciation of the policy of looking into the future as far as possible. I believe it is a fundamental responsibility for us, as engineers, to do this, inasmuch as the managements of our respective companies rely on us to a large extent in connection with making heavy investments which are not readily changed.

Mr. Gamble raised a question in regard to the use of networks as a general principle. That seems to me one of the fundamental necessities if we are to build for the future. Five years ago the Puget Sound Power and Light Company installed an a-c. low-voltage network in the Seattle underground district, which was the first one in the country to employ the principle of power-directional relay protection for interconnecting transformers on different feeders on the same system of mains. After these years of operation, we have felt that it is justified, and therefore, the network principle was considered in connection with future plans for the residential areas.

We had in mind building a distribution network something similar in principle to a fishnet, which might be suspended at a certain elevation above the floor. As various articles were thrown on this fishnet, tending to sag it down at certain points, supports in the form of wire or rope from the ceiling could be installed near those points, which would bring it back to level. They correspond to feeders from the substation, running out to tap the network where the load is heavy, bringing the voltage of the network up to the normal value.

Mr. Heinze referred to Dr. Ryan's prediction of one kilowatt per capita and interpreted that to result in approximately 19,000 kw. per sq. mi., and compared it with the 6250 kw. per sq. mi. load density mentioned in this paper as presently to be anticipated load.

I think that it should be borne in mind that the one kilowatt per capita or 19,000 kw. per sq. mi. includes downtown commercial loads, industrial power, and other loads in the city, whereas the figure of 6250 kw. in the paper refers solely to the residential-lighting and domestic load. In the same areas 13,000-volt loop feeders are run for large industrial power customers and as stated in the paper, their loads are not included in this load-density figure. Data are being collected now by the a-c. low-voltage network subcommittee of the National Electric Light Association, and I have in my hands for the report of that committee load-density figures from various sections of the country in the larger cities and the figures of 19,000 kw. per sq. mi. would be very low indeed unless it was an average of both light and heavy load densities, inasmuch as in the central part of cities like Chicago and New York the load densities aggregate 190,000 to 200,000 kw. per sq. mi. The area immediately surrounding this hotel in Seattle now has a load density of over 100,000 kw. per sq. mi.

Mr. Cunningham asked about our experience with one wire on the ground during trouble. We have had both experience with the delta system, ungrounded, and more recently with the grounded neutral in this respect. We find that grounded-neutral system is very much more apt to trip out the feeder at the station, in case of a feeder on the ground. In fact, with the delta system, we have had partial grounds persist three or four days at a time, which we could not locate, which were not apparently causing any dangerous condition, and sometimes cleared themselves up;

but on the grounded-neutral system, if we get a ground at all, it is very apt to build up into a serious one in a short time, causing the feeder to trip out.

Mr. Cunningham also asked about the re-closing features in our automatic substations on these grounded-neutral 4500-volt feeders. At the present time we have the feeder switches set to reclose after 30 sec. when they trip out from overload and after reclosing three times they lock out. Then, of course, we have to find the trouble on the feeder before it can be put back in service. In a considerable proportion of the cases, however, before the third trip-out occurs, the short circuit either burns itself entirely clear, or for some other reason is broken, so the feeder stays in after the first or second reclosure.

Mr. Gamble asked about butt-treatment and painting of poles. We have not gone into butt treatment to any considerable extent as yet, although a good deal of investigation has been under way, and we have had sample carloads of poles treated several ways, not only with butt-treatment, but with full pressure treatment of the pole as a whole. On Puget Sound, however, conditions are probably the least favorable for economy in connection with the butt-treatment or other treatment of poles, inasmuch as the cedar grows locally and is always obtainable at a lower price than in most other parts of the country; furthermore, we have found that where cedar is reset as a pole in the same soil in which its native growth occurred, it lasts very much longer, and we have thousands of poles which are now 20 years old which were not treated at all originally, and which still have sufficient strength, although the average life will probably not exceed 18 years. Where poles will live 18 to 20 years without treatment, it is a grave question as to whether a large increase in initial investment is to be incurred from which no return will be obtained until at least 18 to 20 years later. As other changes occur, such as the building up of the country, perhaps underground requirements may necessitate the removal of a considerable number of the poles within 20 years.

We paint all poles set in the city a very dark green except the 6 ft. next to the ground, which is painted black. With this arrangement, poles set up through shade trees are very unobtrusive. The tree-interference problem with us is a serious one, as with Mr. Gamble and others, but we have an arrangement whereby once each year we organize a tree-trimming crew which works under the supervision of a representative from the city park board, and the city ordinance permits us to trim trees in parking strips; in fact, requires that it be done by the power company. The trimming work done in this way tends to keep the trees at least out of the primaries.

Mr. Mayer pointed out in the discussion an instance of a water-pipe ground which did not prove reliable. But I think that this is something which it is quite important to emphasize here, and it is not so much the reliability of any one water-pipe ground as it is the reliability in the aggregate of a large number of such grounds. The grounding is done on the 4500-volt grounded-neutral system, primarily as a safety precaution, not as a means of returning neutral current, and in any construction or design for the purposes of safety precaution, a multiplicity of small precautions are more reliable than one single large one. There was a case not long ago in Victoria of a fatal injury where the court, after hearing considerable expert testimony, was of the opinion that the injury was primarily the result of water-pipe grounds not having been made. The local light and power company had made as good grounds as they could, but the soil being very rocky these grounds were entirely inadequate. The local authorities would not permit them to make water-pipe grounds on individual services. After collecting considerable data and testimony, it was the opinion of the court that such grounds should have been provided as a precaution for the safety of the public.

SPANS HAVING SUPPORTS AT UNEQUAL ELEVATION[1]

(Smith)

Seattle, Washington, September 15, 1925

F. K. Kirsten: I wish to congratulate Mr. Smith on his courage in using the catenary equations for the analysis of spans supported from points at unequal elevations, and I would also like to make some supplementary comments.

We know that the more closely we wish to describe a physical phenomenon by means of mathematical formulas, the more involved and unwieldy these formulas become. As an illustration, we might use the simple equation of a circle to express the location in space of a suspended cable, and describe actual conditions with sufficient accuracy although the assumptions involve considerable error. By a closer analysis of the forces in action we find, however, that the parabola describes actual conditions better than the circle and hence the application of the parabola yields greater accuracy, although the mathematical operations are more involved. But still a considerable error is made in the assumption that the weight per unit projected length of the span is uniform along the span. The demand for greater accuracy forces us to base our mathematical formulas upon the assumption that the weight per unit length of span, measured along the span, is constant. This assumption leads us to the catenary, a rather involved mathematical stratagem. This mathematical form is rather difficult to handle, especially if temperature changes accompanied by stress changes must be covered by its use. And still the catenary equation does not describe conditions with absolute accuracy. Since the tension changes along the span, the weight per unit length of cable cannot be uniform. But an attempt to involve this actual condition in the modification of the catenary form would lead to unmanageable expressions.

It will be apparent from a perusal of Mr. Smith's work that the chief difficulty in applying the catenary equation to spans of unequal elevations resides in the introduction of the slope of the suspension points into equations which are already complex enough for ready manipulation. Especially do we feel a naturally increasing reluctance to use the catenary analysis if changes of wind and ice loading together with temperature variations over a considerable range must be accounted for by proper mathematical operations with the catenary form. It is, therefore, in my opinion, a step in the right direction to adhere to the simple catenary forms which Mr. Smith ingeniously introduces into his second method instead of using the first method supported by equations **12, 14** and **15**.

We now have, thanks to Mr. Smith's work, a simple catenary analysis of spans of unequal elevation, and there cannot be any excuse for the use of parabolic forms in the future. It must be remembered, that the catenary method is independent of fixed mass and space units, hence all span conditions which may occur in practise may be expressed by a series of curves from which by interpolation any span, at any slope, for any size or material of cable or any temperature range, may be read at once. This set of curves is as readily applied, without modifications by constants, in continental Europe where the metric system is used as in the lands of inches, pounds and quarts.

Another important finding in Mr. Smith's paper I believe is the discovery that the point of maximum deviation from a straight line connecting any two points of unequal elevation of the cable in suspension occurs midway between the points of support in the middle of the span. This naturally facilitates a check upon the strain of a cable from points of unequal elevation by dropping targets from point B_2 to point A, of predetermined length, the line of vision touching the point of maximum deflection from the line joining these two points.

R. J. C. Wood: Our engineering department has done

1. A. I. E. E. Journal, December, 1925, p. 1352.

a good deal of work in calculating sags and we went into this question of catenary versus parabola quite fully and find that up to about a 1000-ft. span, the parabola is practically a satisfactory curve to use. It must be remembered that after the mathematician has figured out the sag of the line, some fellow in overalls is going to pull that line up as near as he can to the predetermined either sag or tension.

We have been a little undecided as to whether to use the sag or the tension in the line as the criterion. At one time we have used one and at another time the other. We have finally decided to use a dynamometer to measure the tension in the new line. The maximum tension under worst conditions will be about 12,000 lb. and under ordinary stringing conditions may be 6000 or 7000 lb. The dynamometer will probably read within 200 lb. so that any extreme refinement of calculation as to the desired tension is not necessary.

I do not wish to detract in any way from the fine work of mathematicians who calculate these things because, while we may be able to use the laws of a parabola up to a certain point, yet we depend upon the mathematician to tell us where that point is and from where on we should use the more accurate formula. We have ourselves used the catenary formula in all long-span work.

Our spans run up to about 3000 ft. and for that length of span the catenary is necessary. We have had to go a little further than indicated in Mr. Smith's paper, because we have found it quite necessary to calculate clearances to ground under wind conditions. In building the line on a hillside it is not only necessary to know the vertical clearance in still air, but it is quite essential to know that the line will not blow onto the ground when the wind is crosswise, so we have to calculate those conditions of load applied side-ways.

It leads to some very interesting mathematics when there are, for instance, two spans which are dead-ended at the outer ends and hanging on a string of suspension insulators at the middle support, and the wind blows side-ways, because the two spans then no longer remain in a plane but becomes a warped figure and the catenary calculations become quite involved.

C. E. Magnusson: Reference to the parabola by Mr. Wood leads me to bring out a point on the use of hyperbolic functions. Many engineers seem to think that using hyperbolic functions in connection with engineering problems is throwing out a smoke screen to prevent the reader from following the argument. They do not appreciate that for certain types of problems hyperbolic functions become a very convenient means for obtaining accurate solutions. A few years ago while discussing a problem with a nationally prominent engineer, one who has presented many papers before the Institute, I suggested that for an accurate solution hyperbolic functions should be used, and was astounded to find that he had no idea as to what type of problems would require hyperbolic functions. As there may be others in the same predicament let me state that the basis for using circular or hyperbolic functions is simply this: A rotating vector of constant magnitude can be fully represented by circular functions but if the radius vector varies in length while changing in phase position hyperbolic functions fit the case. For example the voltage and current functions along a transmission line vary in magnitude as well as in time-phase position and hence require hyperbolic functions as they cannot be correctly expressed by circular functions.

R. W. Sorensen: I want to second the motion on hyperbolic functions. Dr. Kennelly of Harvard has been trying for years to get us to use them. I have been trying for about fifteen years to get engineering classes to use them, and they use them just as readily as they use trigonometric functions, if you once start them off.

L. J. Corbett: The paper given by Mr. Kirsten[2] a number of years ago is I think a classic in its field of the application of hyperbolic functions to catenaries and long spans. I think Mr. Smith's paper is a very creditable companion paper to that one.

I like particularly Fig. 4 in which the common point A is used as a basis instead of the usual method, although I have not had time to check it and see whether there are particular advantages to be gained over the old method of calculating sag from the inclined line between A and B.

Mr. Smith, in his discussion, brought up also a point in which we were very much interested in the re-insulation of the Carquinez crossing of the Pacific Gas & Electric Company, and that is the difference in expansion between a long span and a contiguous short span. If you can, visualize that crossing. On the south side the anchors are an average of probably 80 ft. from what is called South Tower. Then comes the long span of 4427 ft., then a span of 1350 ft. and then a final span of 335 ft. to the other set of anchors. On the high tower between the 4427-ft. span and the 1350-ft span, was placed a saddle with a sliding top. This was to allow for a difference in expansion between the two spans and to insure a vertical reaction on the tower. We calculated by a number of methods, but chiefly we went back to the original hyperbolic functions, and we thought that, taking all things into consideration we might expect a possible travel of 5 in. We allowed for a travel of somewhat more than that, 8 in. being the final figure allowed,—4 in. in each direction.

The saddle was placed on roller bearings which were immersed in grease so as to offer the very freest possible travel for the cable. The operating department tells me that in the past year according to the marks on the saddle, there has been a travel of only 1 in. so it is questionable how successful our calculations were. There is still room for improvement in our methods of calculation for long and important spans.

M. T. Crawford: I find Mr. Smith's paper very interesting in that he has gone into unequal supports, something which seems to have been more or less avoided in considerations of span problems. I would ask if he could suggest a method of approach toward the solution of a problem that we have. At one previous Pacific Coast Convention, a paper[2] was presented describing transmission-line construction in crossing Stampede Pass in the Cascade Range, where the loading conditions were very extreme at certains times of the winter, and where it was found advisable on account of the unequal loading which would come alternately on successive spans to change all dead-ends to a suspension form of conductor support, doubling up the insulator springs with yoked attachment at the suspension point.

The changes described in the previous paper have proved eminently successful in eliminating the operating troubles we had of jerking insulator strings in two. In trying to calculate the sags which would result from unequal loading in successive spans, we found a complication came into the matter where an entirely suspension form of construction was used, and where the towers were at different elevations, in that heavier loading in one span would pull the suspension strings out of the vertical position. This would make a change in the length of conductor in the span, location of points of support, and other factors, which are assumed constant in most of the ordinary methods of approaching the subject.

We worked it out fairly closely by making assumptions and trials, but found that the extreme condition which we might assume would occur when the insulator string was pulled out to a position approximately tangent to the catenary. This would result in the wire being down in the snow in winter conditions, but we have never found in practise that it went that far, because there was always some tension in the adjoining spans which would prevent the strings from pulling that far out.

I would like to have Mr. Smith add some discussion or suggestions as to how we might approach the problem of calculating the result of extremely unequal loading in the successive spans where the suspension form of construction is used.

2. Transmission-Line Construction in Crossing Mountain Ranges, by M. T. Crawford, A. I. E. E. Transactions, 1923, page 970.

G. S. Smith: I would like to thank Mr. Wood for mentioning a point I did not have time to bring up in the presentation and perhaps did not make clear in the paper; that is, that the method presented was intended primarily for long spans or special problems. It would usually prove too laborious for a single short span. However, where the Kirsten method is applied to the various symmetrical spans encountered in the usual line, it requires only a small amount of additional work to compute, by the method presented here, the remaining spans whose supports are not at the same elevation, since the cable used is commonly uniform throughout.

In discussions by Dr. Magnusson, Professors Kirsten and Sorensen, a more general use of hyperbolic functions was advocated. My experience has been somewhat similar to the instances mentioned. While most of us are more or less reluctant to use hyperbolic functions freely, I believe it is largely because of two reasons: first, we have never become accustomed to think in terms of such functions; and second, in attempting to use them we find it difficult because so few good tables of hyperbolic functions are available. In some previous work in connection with transmission-line design, I found it necessary to compute sufficient tables for this particular use. These tables will be found in one of the University of Washington Experiment Station bulletins referred to in the paper.

Messrs. Corbett and Crawford pointed out some very interesting problems in this same connection: problems which might be termed those of "variable spans." A similar problem was encountered in the design of "The Narrows" span of the Tacoma Lake Cushman Project mentioned in this paper. It was in an attempt to apply the Kirsten method to such problems that I found it desirable to first work out the problem of spans with supports at unequal elevations. Thus far I have found no direct method of attacking such problems, but the possibility of finding such a method seems entirely feasible.

DISTRIBUTION LINE PRACTISE OF THE SAN JOAQUIN LIGHT AND POWER CORPORATION[1]

(Moore and Minor)

Seattle, Washington, September 17, 1925

R. E. Cunningham: I wish to refer to the described methods of voltage regulation in the commercial district at Fresno using regulated circuits, tied in with circuits feeding directly from the bus. It would seen that this would cause considerable circulating current.

L. J. Moore: Referring to Mr. Cunningham's comments, I am submitting herewith actual readings taken on the feeders in the City of Fresno, which are shown in Fig. 16 of the original paper. Readings *A* and *C* were taken with the two regulated feeders carrying the load, and then the switches were closed on the three alley feeders which are unregulated and readings *B* and *D* were taken. Ammeters were installed in current-transformer secondaries on two phases of each circuit and readings taken. Where no ammeter readings are shown for the alley feeders, the switches at the substation were open.

It is noted from the readings that circulating current is set up when the substation bus voltage fluctuates to an extreme degree, and as indicated in the original paper, no attempt is made to keep the switches in when the substation voltage is extremely low. As a matter of fact, the San Joaquin system is not fully regulated and to some extent the system voltage is varied by increased feeders on generators so as to raise the entire system at time of peak loads. This naturally tends to keep up the bus voltage in Fresno at the time of system peak and reduces the amount of regulation required, and this, of course, naturally limits the circulating current. For that reason it has been possible to operate all of these lines tied together to good advantage on numerous occasions.

ILLUMINATION ITEMS

By the Lighting and Illumination Committee

DEPRECIATION OF THE REFLECTING PROPERTIES OF WHITE PAINTS

The illuminating engineer of today has made much progress in a study of the various factors which are involved in the installation and maintenance of an efficient and effective lighting system. He knows full well the influence that the type of luminaire, its spacing and mounting height and the color of the surroundings have on the character of the illumination produced. He is also quick to realize the uselessness and ineffectiveness of even the best of lighting systems if they are allowed to depreciate because of an accumulation of dust and dirt. He knows, too, that the majority of lighting systems are largely dependent for their effectiveness upon the general lightness in color of the surroundings. The illuminating engineer is not alone in his interest in these factors, however, for the architect, the plant executive and the building manager should be concerned equally as much, if not actually more, in the adequacy of the lighting system.

In view of the fact that light colored ceilings and side walls play an important part in the effectiveness of lighting, and also that pure white paint is generally conceded to be the most desirable for these surfaces—at least from an illumination standpoint—a series of tests* have recently been conducted on the reflecting properties of various kinds of white oil paints. The object of these tests was to determine the kind of white paint having the highest initial reflecting power when applied to various surfaces and also to determine the rate of depreciation of the various paints under different conditions. Twenty-six samples of paints were selected and applied to the test surfaces in accordance with the recommendations of the various paint manufacturers.

*"The Reflecting Properties of White Interior Paints of Varying Compositions," a paper presented by A. L. Powell and R. B. Kellogg, before the New York Section of the Illuminating Engineering Society on Nov. 12, 1925.

1. A. I. E. E. Journal, November, 1925, p. 1201.

Three different kinds of surfaces were used in order to determine whether or not the type of surface had any effect on the reflecting properties and rate of depreciation of the paint. These test surfaces of wood (white pine), finishing concrete, and galvanized sheet iron were made into the convenient test size of 5 by 7 inches. The concrete samples were aged for eight weeks before they were used in order to lessen the possibility of destructive chemical action.

Two sets of specimens were prepared with each of the 26 paints on each of the three different surfaces. One of these sets were sealed up in a dust proof cabinet with a glass front, and exposed to direct north skylight so as to determine the depreciation of the paint due to light alone.

The other set of specimens was suspended close to the ceiling in a factory interior in which a certain amount of very small metallic and graphic particles were suspended in the atmosphere. In addition to these, the atmosphere contained a fairly high percentage of the products of combustion as produced by the many gas burners used in the drawing of tungsten wire. The test on these specimens would show the acquired depreciation which a paint would have under conditions which might be considered slightly more severe than normal industrial service.

The entire test covered a period of about 20 months and photometric readings were taken of each sample at intervals of 16, 31, 49, 71 and 88 weeks. It can be readily seen that this involved a considerable amount of photometric work and for this reason a rather inexpensive modified sphere or icosahedron was constructed for the purpose. In addition to this modified sphere, a small photometer and projection lantern were required.

In the actual determination of the reflection factor of a sample which has been placed in the sphere, the sight tube of the photometer is first directed upon the walls of the sphere and a reading of apparent foot-candles is made. This is considered to be the illumination incident upon the sample. The photometer is then directed toward the sample and a second reading is taken. This is considered the light reflected from the sample. The ratio of those two readings is, of course, the reflection factor of the sample. In order to maintain the accuracy of the results obtained a freshly scraped block of commercial magnesium carbonate was used as a standard at regular intervals.

The results of the test as a whole, disclosed some interesting facts. It was found that the initial reflection factor of the 26 types of white paint tested showed an average value of 81.1 per cent. The maximum value found was 87.6 per cent for a flat paint with titanox lead and free zinc as pigment material. While the minimum reflection factor was 75.5 per cent for a flat paint with lithophone as a pigment material.

The average results as obtained from all the specimens in the two sets of tests reveal the fact that with the specimens in the glass covered cabinet, the character of the material to which the paint is applied has practically no effect on the rate of depreciation, while with the set of specimens exposed to factory conditions the metal and concrete samples drop off somewhat more rapidly than the wood specimens. The curve of Fig. 1 shows this clearly.

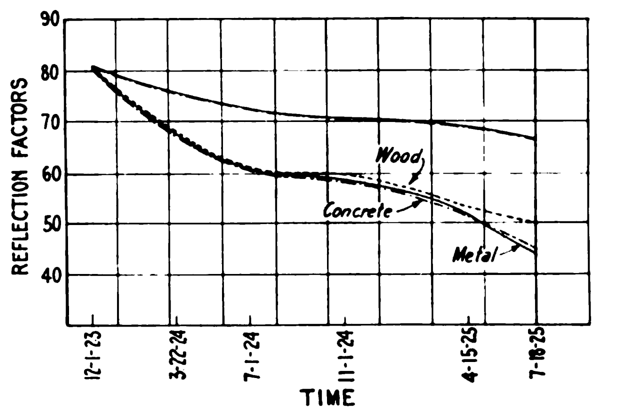

FIG. 1—AVERAGE DEPRECIATION CURVES OF ALL SPECIMENS BASED ON THE MATERIAL TO WHICH THE PAINT IS APPLIED
Upper curve —Cabinet set
Lower curve —Factory set

The curve in Fig. 2 was obtained by grouping all specimens having the same type of finish (gloss, egg-shell or flat) regardless of composition, and averaging the test values. Initially the flat white group shows the highest reflection factor and, contrary to common opinion, the average rate of depreciation is about the same for all types of finishes. This may be explained by the particular character of the dirt which accumulated in the factory test. It was of a slightly greasy

carbon nature which would cling with equal tenacity to flat or glossy surfaces.

By grouping specimens of the same pigment together and averaging values regardless of the character of finish, the results obtained seemed to indicate that the paint having titanox as a part of the pigment had the

TABLE I
THE REFLECTING PROPERTIES OF WHITE PAINTS

Specimen No.	Basic Pigment	Type of finish	Initial reflection factor	Average reflection factor during 20 months: Cabinet Specimens	Average reflection factor during 20 months: Factory Specimens	Appearance at end of test

33	Lth and Mgsi Silicate	Flat White	80.0	72.5	62.2	White
34	Lth	Eggshell	81.4	73.5	61.7	White
35	Lth	Gloss	82.1	73.6	63.2	Grayish

highest initial reflection factor, with those of lithophone, lead, and zinc following in the order named. The rate of depreciation of the different groups is in this order also. These results, however, do not tell the whole story, for there may not be enough varieties of certain types to give good average figures, whereas with other types there may be instances of high values grouped with exceptional low values.

The question naturally arises as to whether a distinct chemical action took place with those specimens exposed to factory conditions. At the conclusion of the test all samples which had been hanging in the workroom were removed and carefully cleaned with a fine grade of soap and hot water. This was more carefully done than would have been the case if an ordinary workman was called upon to clean a paint surface. Readings were then taken of each specimen and it was found, in general, regardless of finish or composition, that the reflection factor of the cleaned specimen was very close to that corresponding specimen which had been kept in the glass cabinet.

The grand general average showed the factory specimens after cleaning to be about 2 per cent below those of the control set. The maximum departure was 5.7 per cent less, and on the other extreme, one specimen showed 1.8 per cent higher reflecting power. These deviations are so relatively small as to be well within the limits of error of such measurements.

The question naturally arises as to what is the best type of paint for different conditions, and one must stop to analyze what is required of the paint. The initial reflection factor certainly does not tell the whole story. One paint may have a very high initial value and its rate of depreciation may be quite rapid; another may have a lower initial reflection factor and yet over a period of time actually reflect more light—in other words, it depreciates at a lower rate.

DIELECTRIC CONSTANT, POWER FACTOR AND RESISTIVITY OF RUBBER AND GUTTA-PERCHA

Technologic Paper, No. 299, of the Bureau of Standards, by H. L. Curtis and A. T. McPherson, comprises a careful study of the dilectric constant, power factor, and resistivity of rubber and its compounds, and of gutta-percha. Crude rubber has a lower dielectric constant than either gutta-percha or vulcanized rubber, the value of the latter depending on the conditions of vulcanization. Vulcanization by sulphur alone produces a higher dielectric constant than vulcanization with the aid of an accelerator. The addition of a filler generally increases the dielectric constant, sometimes by as much as 200 or even 300 per cent. Dried samples of both rubber and gutta-percha have a lower dielectric constant than those which contain absorbed water. Vulcanized rubber may have a lower dielectric constant than gutta-percha.

The power factor of crude rubber is about the same as that of gutta, the hydrocarbon of gutta-percha. Crude rubber, vulcanized rubber, and gutta-percha all have about the same resistivity. The incorporation of some substances in vulcanized rubber increases the resistivity.

Midwinter Convention February 8-11

All is ready for the opening of the Midwinter Convention in New York, February 8-11, with headquarters at the Engineering Societies Building. The advance indications show that there will be a large attendance. An unusually large number of requests for advance copies of the technical papers proves that the topics to be presented are of wide interest. The social events also will be of such quality that they will be thoroughly enjoyed.

Among the technical subjects to be presented are transmission power limits, protection, control systems, electrical machinery, measurements, insulation and dielectric absorption, electromagnetism, electrophysics, communication and sound reproduction, and furnace-resistor design. In the list below the titles of all papers are given.

An informal smoker at which entertainment will be furnished by some high-grade talent will be held at the Hotel Astor on the evening of Tuesday, February 9th. A delightful evening is assured on the evening of Wednesday in the dinner-dance which will be held at the Hotel Astor. Paul Whiteman's Piccadilly Players will furnish the music. A prominent speaker will be heard in an address of general interest on Thursday evening in the Engineering Societies Building.

Inspection trips will be made to a number of interesting places including the following: The new Holland Tunnel (the vehicular tunnel under the Hudson River), Broadcasting Station W.E.A.F. of the American Telephone and Telegraph Company, The Edison Lighting Institute of the Edison Lamp Works, the Loening Airplane Factory, Kearny Power Station of the Public Service Electric Power Company, Hudson Avenue Station of the Brooklyn Edison Company, Hell Gate and Sherman Creek Stations of the United Electric Light and Power Company, the Bell Telephone Laboratories and a machine-switching central telephone office. The regularly scheduled trips will be made on Wednesday afternoon though small parties may visit some of the places at other times.

Two intensely interesting lectures, on topics which engineers do not often have the chance to hear presented by foremost authorities, will be delivered on Thursday evening, in the Engineering Auditorium beginning at 8:15 P. M.

Dr. Alexis Carrel will talk on some developments of modern biological research. A motion-picture demonstration will illustrate the points of the address. Dr. Carrel is a member of the Rockefeller Institute for Medical Research and a winner of the Nobel Prize. He is widely known for his accomplishments in the field of medical and biological research and, in addition, is a magnetic speaker.

Dr. Carrel will deal particularly with the life of tissues outside of the organism. The motion pictures will show the actual growth of living cells outside of the living organisms from which they were taken. Some strains of cells in Dr. Carrel's laboratory have been living and growing under artificial conditions since 1912.

Major Allen Carpe, of the American Alpine Club, will describe "The Ascent of Mount Logan." This mountain is 19,850 ft. high, and was the highest unclimbed mountain in North America when the ascent was made last summer. This also will be illustrated with motion pictures.

Mount Logan, in Yukon territory, is probably the largest mountain mass in the world, in the center of the largest glacial area outside of the polar region. On this expedition, Major Carpe obtained some most remarkable motion pictures covering the work of approach and ascent of this mountain, including packing and hand-sledding over the lower glaciers, establishment of the higher camps and pictures taken on the actual summit of the mountain.

All local arrangements have been made by the Convention Committee and subcommittees. The general committee is as follows: H. A. Kidder, Chairman, H. H. Barnes, Jr., G. L. Knight, E. B. Meyer and L. F. Morehouse. Chairmen in charge of features are as follows: Entertainment, H. H. Barnes; Smoker, G. W. Alder; Inspection Trips, H. Y. Hall; Dinner-Dance, J. B. Bassett, Special Meeting, H. S. Sheppard and Finance, G. L. Knight.

PROGRAM OF THE MIDWINTER CONVENTION

MONDAY MORNING

Registration
Committee Meetings

MONDAY AFTERNOON

TRANSMISSION SESSION

1. *An Investigation of Transmission-System Power Limits*, C. A. Nickle, and F. L. Lawton.
2. *Calculation of Steady-State Stability in Transmission Lines*, Edith Clarke.
3. *Practical Aspects of System Stability*, Roy Wilkins.
4. *Further Studies of Transmission Stability*, R. D. Evans and C. F. Wagner.
5. *Transmission Systems with Over-Compounded Voltages*, H. B. Dwight.

MONDAY EVENING

DIELECTRICS AND INSULATION

6. *Dielectric Absorption and Theories of Dielectric Behavior*, J. B. Whitehead.
7. *Theory of Absorption in Solid Dielectrics*, V. Karapetoff.
8. *Ionization Studies in Paper-Insulated Cables*, C. L. Dawes and P. L. Hoover.

TUESDAY MORNING

PROTECTION, CONTROL AND BUS CONSTRUCTION

9. *Operating Performance of a Petersen Earth Coil-II*, J. M. Oliver and W. W. Eberhardt.
10. *Theory of the Auto-Valve Lightning Arrester*, Joseph Slepian.
11. *Current-Limiting Reactors with Fire-Proof Insulation on the Conductor*, F. H. Kierstead.
12. *Temperature Rise and Losses in Structural-Steel Members Exposed to the Fields from A-C. Conductors*, O. R. Schurig and H. P. Keuhni.
13. *Carrying Capacity of Sixty-Cycle Busses for Heavy Currents*, Titus G. LeClair.
14. *Supervisory Systems for Electric Power Apparatus*, Chester Lichtenberg.

TUESDAY AFTERNOON

TWO PARALLEL SESSIONS, A AND B

(A) ELECTRICAL MACHINERY

15. *Experimental Determination of Losses in Alternators*, Edouard Roth.
16. *No-Load Copper Eddy-Current Losses*, Thomas Spooner.
17. *Mechanical Force Between Electric Circuits*, R. E. Doherty and R. H. Park.
18. *Concluding Study of Ventilation of Turbo-Alternators*, C. J. Fechheimer and G. W. Penney.

(B) COMMUNICATION AND SOUND REPRODUCTION

19. *The Development and Application of Loading for Telephone Circuits*, Thomas Shaw and William Fondiller.
20. *Cipher Printing-Telegraph Systems*, G. S. Vernam.
21. *Refraction of Short Radio Waves in the Upper Atmosphere*, W. G. Baker and C. W. Rice.
22. *High-Quality Recording and Reproducing of Music and Speech*, J. P. Maxfield and H. C. Harrison.

TUESDAY EVENING

Smoker

WEDNESDAY MORNING

ELECTRICAL MACHINERY

23. *Parameters of Heating Curves of Electrical Machinery*, V. Karapetoff.
24. *Rating of Electrical Machinery as Affected by Altitude*, C. J. Fechheimer.
25. *Motor Band Losses*, Thomas Spooner.
26. *Starting Characteristics of Polyphase Squirrel-Cage Induction Motors and Their Control*, H. M. Norman.

WEDNESDAY AFTERNOON

Inspection Trips

WEDNESDAY EVENING

Dinner-Dance, (Hotel Astor)

THURSDAY MORNING

ELECTROMAGNETISM AND PHYSICS

27. *Calculation of Magnetic Attraction*, Th. Lehmann.
28. *The Magnetic Hysteresis Curve*, Hans Lippelt.
29. *Properties of the Single Conductor*, Carl Hering.
30. *Heaviside's Proof of His Expansion Theorem*, M. S. Vallarata.

THURSDAY AFTERNOON

MEASUREMENTS, MACHINERY AND INDUSTRIAL

31. *A New Wave-Shape Factor and Meter*, L. A. Doggett, J. W. Heim and M. W. White.
32. *Practical Application of Vibration Instruments to Rotating Electrical Machines*, J. Ormondroyd.
33. *A High-Frequency Voltage Test for Insulation of Rotating Electrical Machinery*, J. L. Rylander.
34. *The Cross-Field Theory of Alternating-Current Machines*, H. R. West.
35. *Rating of Heating Elements for Electric Furnaces*, A. D. Keene and G. E. Luke.

THURSDAY EVENING

Some Modern Developments of Biological Research, by Dr. Alexis Carrel, Member Rockefeller Institute for Medical Research.

The Ascent of Mount Logan, by Major Allen Carpe, of the American Alpine Club.

Regional Meeting at Cleveland

MARCH 18-19

Plans are practically completed for the Regional Meeting which will be held in Cleveland on March 18-19 with headquarters at the Hotel Cleveland. This will be a two-day meeting and papers will be devoted to the subjects of sectionalized electric drive and electric refrigeration. There will be addresses by prominent men, a dinner, a meeting of Branch Counsellors of the Second District and inspection trips.

SECTIONALIZED ELECTRIC DRIVE

In recent years no more interesting problem has been presented to the electrical engineer than the interlocking of individual motor drives into a controlled group drive. The problem has been so successfully solved that it is possible to control the speed of the group over a wide range and still maintain no variation between the relative speeds of the individual motors of the group. Furthermore, at the will of the operator the fixed relation may be adjusted over a considerable range.

This subject will be presented and discussed before the Institute for the first time at the Cleveland Meeting in the sessions on Thursday, March 18. The various systems will be described by S. A. Staege of the Westinghouse Electric and Mfg. Company, R. N. Norris of the Harland Engineering Company and H. W. Rogers of the General Electric Company.

Plans are being successfully carried out to have present a large number of paper-mill engineers and executives to enter into the discussion of these papers. It was in the paper-mill field that the demand for such a synchronized group drive originated. There it has been so successfully applied that paper has been manufactured at speeds higher than 1000 ft. per min.

It is probable that in many other lines of industry there exist fields for such a drive. Wherever it is necessary to provide for a variation in the speed of the group as a whole and still maintain synchronism between the individual motors of the group a possible field of application exists provided the investment is justified by the advantage secured.

FRIDAY SESSIONS

Two unusual speakers of national reputation have been secured for the second day of the meeting. C. F. Kettering, President of The General Motors Research Corporation, will speak on "Electrical Refrigeration," a subject in which every householder as well as every engineer in interested.

Past-President Farley Osgood, will deliver an address under the heading "Engineering and Humanity."

A dinner will be held at the Hotel Cleveland on Thursday evening, at which a message of welcome will be given by Manager Hopkins of the City of Cleveland and an address will be made by a well-known speaker.

A special inspection trip will be made on Friday evening to the National Lamp Works of the General Electric Company at Nela Park. A number of other interesting trips also may be taken by those at the meeting.

Thorough arrangement of plans and details is in the hands of an able general committee and subcommittees. The general committee consists of: Chairman, A. M. MacCutcheon; Secretary, C. S. Ripley; A. G. Pierce, Vice-President of Second District; C. L. Dows, Ralph Higgins, A. F. E. Horn and Nathan Shute. The chairmen in charge of the subcommittees are: L. D. Bale, Transportation; H. B. Dates, Program; C. L. Dows, Reception; H. L. Grant, Publicity; G. A. Kositzky, Finance; A. M. Lloyd, Registration; E. H. Martindale, Attendance; C. W. Rakestraw, Dinner, and I. M. Van Horn, Trips.

Niagara Falls and Madison, Wis., Regional Meetings in May

Two regional meetings are planned for the coming May, a meeting at Madison, Wis., being scheduled for May 6 and 7 and one at Niagara Falls, N. Y., for May 26-28.

The meeting at Madison will be held under the auspices of Geographical District No. 5. A two-day program is planned and the papers will cover the subjects of rural electrification, power transmission and distribution, cooperative research relations between colleges and industries, and radio.

The committee in charge of the Madison meeting is as follows: Edward Bennett, Vice-President of District No. 5, J. B. Baily, A. J. Deward, H. R. Huntley, L. E. A. Kelso, Carl Lee and R. G. Walter.

The Niagara Falls meeting which will be held by District No. 1 will be a three-day affair. The technical papers will cover methods of dielectric power-factor measurement, transmission, power plants and other subjects. Arrangements are being made for a special illumination of the Falls, a trip down the Gorge, visits to generating and manufacturing plants and entertainment features.

The general committee in charge of the Niagara meeting consists of H. B. Smith, Vice-President of District No. 1; A. C. Stevens, Secretary; J. R. Craighead, E. D. Dickinson, J. A. Johnson, A. E. Soderholm and A. W. Underhill. J. A. Johnson is chairman of the local committee on arrangements.

Student Convention at Cambridge

Plans are under way for a Northeastern District A. I. E. E. Student Convention to be held in Cambridge, Mass., in the Spring. Arrangements are being made by a student committee headed by the Chairman of the Massachusetts Institute of Technology Branch acting with the advice and assistance of the Executive Committee of the Boston Section.

Tentatively, it is proposed to hold a morning session at which two or three student papers will be presented and a banquet in the evening to be held jointly with the Boston Section. The afternoon will be devoted to a number of inspection trips to points in and about Boston. Included in these trips will be the well-known Edgar Station of the Edison Electric Illuminating Company of Boston and the laboratories of the electrical Engineering Department of Massachusetts Institute of Technology.

Future Section Meetings

Baltimore

Mercury-Arc Rectifiers as Applied to Power Development, by H. D. Brown, General Electric Co., Johns Hopkins University. February 19, 8:15 P. M.

Mechanical Power and Trend of Civilization, by C. E. Skinner, Westinghouse Electric & Mfg. Co., Engineers' Club. March 19, 8:15 P. M.

Boston

High-Tension Cable Testing, by F. M. Farmer, Electrical Testing Laboratories. Meeting to be held in the new 750,000-volt testing laboratory of the Simplex Wire & Cable Co., Boston, Mass. February 19.

Connecticut

The Value of Patents. Stamford. February 16.

Power Production. Hartford. March 9.

Lehigh Valley

Automatic Control of Centrifugal Pumps, by Otto Haentjens, Barrett Haentjens & Co., and

Wallenpaupack Hydro-Electric Development, by N. G. Reinecker, Pennsylvania Power & Light Co., Wilkes-Barre. March 26.

Pittsfield

Lightning. Round-Table Discussion, Leader, F. W. Peek, Jr., General Electric Co. February 23.

Earthquakes and Volcanoes, by B. R. Baumgardt, Scientist and Explorer. Illustrated. February 16.

Artificial Refrigeration, by A. R. Stevenson, Jr., General Electric Co. Illustrated. March 2.

Round-Table Discussion. March 9.

St. Louis

Development of Electric Power Generation and Distribution, by Col. Peter Junkersfeld, President, McClellan & Junkersfeld. March 17.

American Engineering Council

ANNUAL MEETING, WASHINGTON, D. C., JANUARY 13-15, 1926

The Annual Meeting of the Amerian Engineering Council was held in Washington, D. C., at the Mayflower Hotel, January 13-15, 1926. About one-hundred delegates and interested visitors were in attendance. The official delegates came from all parts of the country and represented the various national, state and regional engineering societies composing the membership of the Council. In the absence of President James Hartness, of Vermont, who is recovering from a long illness, the meeting was presided over by Vice-President Gardner S. Williams.

The sessions of the Assembly were marked by keen interest, abiding confidence, and constructive action. Those in attendance were gratified with the work accomplished and were inspired with the great sphere of usefulness immediately at hand.

The meetings of the Executive Committee and the Administrative Board of the Council were held on Wednesday, January 13th, at which various matters were considered and recommendations formulated for the consideration of the Assembly of the Council on the following day. These matters are included in the following summary of the principal topics discussed and actions taken by the Assembly on January 14th and 15th.

Department of Public Works and Domain

A conference on Public Works was attended by official representatives from sixty-three engineering and allied technical associations. The Conference approved the draft of a bill providing that the Department of Interior be named the Department of Public Works and Domain. The drafted bill calls for the following four assistant secretaries: an Assistant Secretary having administrative jurisdiction over the Design and Supervision of Architectural Works; an Assistant Secretary having administrative jurisdiction over the Design and Supervision of Engineering Works; and Assistant Secretary having administrative jurisdiction over the administration and execution of the Construction Work of the Department of Public Works and Domain; and an Assistant Secretary having administrative jurisdiction over the Public Domain. Under the provisions of the bill all subdivisions of the Federal Government of an architectural, engineering and construction character would be transferred to the Department of Public Works and Domain.

The Bill will be introduced in the Senate by Senator Jones, of Washington, and in the House of Representatives by Congressman Wyant, of Pennsylvania.

Government in Industry

The Council had been invited to become an affiliated member of the Conference on Government in Industry. This it declined to do. However, it voted to lend its moral support to the purposes of the Conference. This it did by declaring it to be the sense of American Engineering Council that the Government should not trespass upon the field of industry unless it was satisfactorily shown that the Government could better engage in a particular business than private enterprises.

Federal Water Power Commission

In view of the fact that bills have been introduced into Congress proposing to remove the Tennessee and Colorado Rivers from the jurisdiction of the Federal Power Commission, and since other legislation is pending which, if passed, will undermine the Commission, the Assembly approved a resolution of disapproval of all such legislation. The Assembly instructed its Water Power Committee and officers to use all possible means to defeat any legislation that tends to impair the usefulness of the Commission or to destroy the functions thereof as provided for in the enabling act.

Salaries of Federal Judges

The Assembly unanimously endorsed House Bill 3831, "A bill to increase the salaries of Federal Judges," and instructed its Patents Committee to exert its efforts to secure the passage thereof.

Patents

The Assembly passed a resolution authorizing its officers to endeavor aggressively to secure a new building for the Patent Office. They were instructed to enlist the active support of all interested groups. The urgent need for a new building and modern equipment was clearly set forth by the Executive Secretary, who has been serving on a Committee on Patent Office Procedure, appointed by the Secretary of Interior and continued by the Secretary of Commerce.

Street and Highway Safety

Mr. W. B. Powell, Chairman of the Committee on Street and Highway Safety, submitted a most suggestive report. The committee recommended that American Engineering Council alone or in cooperation with other organizations have a study made of:

A. Traffic control signals.

B. Directional and general traffic signs for city streets.

C. Analysis of the physical factors entering into the efficient operation of street intersections.

D. Analysis of the most efficient methods of turns at intersections.

The Assembly approved the report and referred it to the Administrative Board for consideration of ways and means to having the study made.

Reclamation

Chairman H. B. Walker, speaking for the Committee on Reclamation, said the future policy of Federal reclamation should embody the principle that previous to inaugurating any project, there shall be ascertained:

A. The producing capacity of the land.

B. The ability of the land and the project to meet the cost of construction, operation and maintenance.

C. The practical occupation of the land by responsible settlers.

The Committee recommended that American Engineering Council have made under its direction a thorough and an important study of:

A. The fundamental principles involved in a reasonably fixed policy of Federal Reclamation.

B. An administrative plan looking toward the creation of a Federal corporation, controlled by a small board of directors, authorized to administer and enforce congressional acts relating to reclamation.

C. Development of a land settlement plan which may be practical under such corporate administration.

The Assembly adopted the report of the committee and referred it to the Administrative Board with power to have such a study made if means for financing it can be obtained.

Program of Research

Dr. H. E. Howe, Chairman of the Committee on a Five-Year-Program of Research, presented a progress report which was enthusiastically adopted. This program proposes the following studies:

Waste in Agriculture, with special reference to the engineering phases thereof.

Survey of Waste in Industries using Agricultural Products as Raw Materials.

Waste of Power, in the realm of generation, transmission and use of power obtained from coal, oil and gas.

Reclamation of Material Wastes, such as metals, forest products, city refuse and garbage.

The Engineering Approach to the Problem of Labor Supply.

Training and Employment of the Partially Incapacitated.

Industrial Fatigue.

Integration of Industry.

This program contemplates the expenditure of approximately $350,000 during the next five years.

On the basis of past experience and a known source of interest, it is believed the necessary funds can be secured.

Civil Aviation

Announcement was made that the report on Civil Aviation had been completed and issued in book form. This report, made jointly by the Department of Commerce and American Engineering Council, has been most favorably received and will undoubtedly serve a useful purpose during this session of Congress.

Survey for 1926

The Council has secured $25,000 with which to defray the expense of its survey for 1926. This survey will have to do with safety in industry. The details are being developed and a further announcement concerning it will be made in the near future.

Meeting of Washington Sections.

On the evening of January 13th, the delegates in attendance were the guests of the Washington Sections of the A. S. M. E. and the A. I. E. E., at a dinner at the Cosmos Club. Messrs. A. F. Horn, Chairman of the A. I. E. E. Section, and Arthur Adelman, Chairman of the A. S. M. E. Section, acted as "alternating" toastmasters. The following officers and Past Presidents of the A. S. M. E. and A. I. E. E. were called upon and made brief addresses:

William L. Abbott, A. W. Berresford, M. E. Cooley, Ira M. Hollis, F. L. Hutchinson, Dexter S. Kimball, F. R. Low, Farley Osgood, Calvin W. Rice, E. W. Rice, Jr., and Charles F. Scott.

The principal speaker of the evening was Dr. Harold G. Moulton, Director of the Institute of Economics, Washington, D. C., who gave an exceedingly interesting and instructive talk on "The French Debt Problem."

Banquet

The Council sessions concluded with a Banquet at the Chevy Chase Club, Friday evening, January 15th. Mr. Gardner S. Williams, Acting President, presided at the Banquet. A short address was given by President-elect Dexter S. Kimball. The principal speakers were Honorable Hubert Work, Secretary of the Interior, and Honorable D. R. Crissinger, Governor of the Federal Reserve Board. Many prominent members of Congress and government officials attended.

Officers Elected

The officers elected at this Annual Meeting are:

President, Dexter S. Kimball, Dean of Engineering, Cornell University, Ithaca, New York.

Vice Presidents, Gardner S. Williams, Ann Arbor, Michigan, (re-elected) and I. E. Moultrop, Boston, Massachusetts.

Treasurer, Dr. H. E. Howe, Washington, D. C. (re-elected)

Executive Secretary, L. W. Wallace, Washington, D. C., (re-elected by the Administrative Board)

Hold-Over Officers are:

Vice Presidents, O. H. Koch, Dallas, Texas; and A. W. Berresford, New York, N. Y.

The representatives of the A. I. E. E. present were:

A. W. Berresford, John H. Finney, M. M. Fowler, H. M. Hobart, F. L. Hutchinson, William McClellan, Farley Osgood, E. W. Rice, Jr., C. F. Scott, and C. E. Skinner.

Announcement was made of the names of the representatives who will constitute the Administrative Board for the year 1926, consisting of the President, the four Vice Presidents, the Treasurer and representatives of the national societies and the regional districts; the delegation to represent the A. I. E. E., in addition to Vice-President Berresford is composed of:

John H. Finney, Washington, D. C.; D. C. Jackson, Boston, Massachusetts; Farley Osgood, Newark, New Jersey; E. W. Rice, Jr., Schenectady, New York; Charles F. Scott, New Haven, Connecticut, and C. E. Skinner, Pittsburgh, Pennsylvania.

Four alternates were also designated namely:

M. M. Fowler, Chicago, Illinois; William McClellan, New York, N. Y.; A. G. Pierce, Cleveland, Ohio; and E. C. Stone, Pittsburgh, Pennsylvania.

John Fritz Medal Awarded to Edward Dean Adams

The John Fritz medal, established in 1902 in honor of John Fritz, one of the great pioneers in the iron and steel industry to be awarded annually for notable scientific and industrial achievement—the highest honor bestowed by the engineering profession of this country—was on January 15, awarded by the John Fritz Medal Board to Edward Dean Adams, for achievement as "an Engineer, Financier, Scientist, whose vision, courage and industry made possible the birth at Niagara Falls of hydroelectric power." The presentation will be made at a later date.

Born in Boston Mr. Adams has resided in New York since 1878. He was graduated as a bachelor of science from Norwich University in 1864 continuing the pursuit of his engineering studies at Massachusetts Institute of Technology. Mr. Adams has been a fellow of American Society of Civil Engineers since 1891, an associate of American Institute of Electrical Engineers since 1910, Vice-Chairman of Engineering Foundation since its inception, and, for years, an active member and officer of Engineering Societies Library.

It was by his decision that alternating current was chosen for the epoch-making plant of The Niagara Falls Power Company in 1891 as well as the transmission of the power by wire to Buffalo. He personally made extensive studies of the latest forms of electric generators and water turbines in Europe and America. In spite of contrary opinions he adhered to his momentous decision with regard to the kind of electric current and equipment to be used emphatically expressed by Edison and Sir William Thomson (later Lord Kelvin) and now alternating current and direct-connected hydroelectric units are almost universally employed for power development and transmission.

Mr. Adams has been a patron of many expeditions for observing total eclipses of the sun and of other scientific investigations personally participating in some of them. He is a member of the National Research Council, the American Museum of Natural History, for many years a trustee of the Metropolitan Museum of Art, and a patron of the fine arts in this and other countries.

On April 9 last year, a host of friends, men of national and international reputation in many fields of human endeavor, entertained Mr. Adams at a dinner at the Waldorf-Astoria Hotel in celebration of his seventy-ninth birthday.

Most of his long and intensely active business life has been devoted to important enterprises combining engineering and finance. He took a leading part in the organization and reorganization of the numerous railroads, including the West Shore, Central of New Jersey, Western Maryland and the Northern Pacific. Out of innumerable small companies he created the American Cotton Oil Company, led in establishing the All-America Cables, and has had no unimportant share in many another industrial undertaking. For fifteen years he was a member of the banking firm of Winslow, Lanier & Company, and for twenty-one years American representative of the Deutsche Bank, of Berlin.

Relation of Diesel Electric Locomotive to Electrification

A meeting of great interest in these days of acute transportation problems is to be held jointly by the four Founder Societies, the A. S. C. E., A. I. M. E., A. S. M. E. and A. I. E. E. on Thursday, February 18, 1926, 8 p. m., Engineering Societies Building, 33 West 39th St., New York, N. Y. The subject "The Relation of the Diesel-Electric Locomotive to Electrification" will be developed by three speakers: C. H. Stein, General Manager, Central Railroad of New Jersey; Hart Cooke, McIntosh and Seymour Company; and N. W. Storer, Westinghouse Electric and Manufacturing Company.

Mr. Stein will speak of heavy electrification problems as seen by the operating officials with relation to short haul, switching and terminals, showing how single units with their own power plants might fit, and also supplement trunk line electrification. Mr. Hart Cooke will describe the characteristics of the Diesel-Electric Locomotive and give some results of operation. He will show why and in what way it will as a prime mover meet requirements. Mr. Storer will deal with the electrical characteristics of the Diesel and cover the problem from the standpoint of the electrical engineer and electrical equipment. The meeting will be presided over by H. A. Kidder, Supt. of Motive Power, I. R. T., Chairman, New York Section A. I. E. E. and George J. Ray, Chief Engineer, D. L. & W. R. R., Chairman, New York Section A. S. C. E.

ENGINEERING FOUNDATION

A PLATFORM FOR ENGINEERING FOUNDATION
An Announcement

Engineering advances by continual gain and diffusion of new knowledge. Organizing for effective conduct of research under the auspices of the four national American Societies of Civil, Mining and Metallurgical, Mechanical, and Electrical Engineers, has, however, not been a simple task. Nevertheless, important progress has been made recently.

Technical investigations have been conducted by these Societies severally for years; but there has been little correlation and no comprehensive program. Only within a decade have engineers come to understand research in the same sense as scientists. Ambrose Swasey, by his far-sighted suggestion in 1914 of an engineering research foundation, and a gift for the beginning of its endowment, compelled study of this problem.

Then came the great war and the organizing of scientists and technologists to aid the Government should our country become involved, as in 1916 appeared inevitable. Engineering Foundation assisted, therefore, in establishing National Research Council and cooperated with it through the war and reconstruction. Indeed, it has been said repeatedly that if the Foundation had

accomplished nothing else, this service alone would have justified Mr. Swasey's gift. Scientists and engineers repeatedly gave practical demonstration of the usefulness of research in meeting war emergencies. In peace, also, wisely directed cooperative research can be useful, for it can aid in solving urgent problems, and, besides, add to the store of knowledge on which are based progress in industry, advancement of engineering practise and improvement of technical education, for the greater satisfaction of human needs and desires.

In 1923, Engineering Foundation again found itself facing its primary problem, but with experience accumulated and useful work done. Its Founder Societies in the interval had progressed in research and in development of their organizations and their joint relations. Together they attacked again this problem so important to the profession and the country. Naturally there has been variety in conception of the form and functions of the Foundation and of the relations between it and the Societies. Out of prolonged consideration a plan has emerged which assures progress and achievement. Its fundamentals are embodied in a Platform for Engineering Foundation, adopted at a meeting of its Board December 10, after approval of a draft by the governing body of each Founder Society based on a unanimous recommendation of their Joint Conference Committee, composed of their presidents and secretaries.

Platform for Engineering Foundation

Desiring to promote active and wisely directed research as a means to scientific and technical progress and believing that systematic cooperation by Engineering Foundation and the several Founder Societies is essential to any development of the research work of the Societies commensurate with the dignity, influence and resources of the profession, Engineering Foundation, while reserving entire liberty of action under the authority conferred upon it by the Founder Societies, through United Engineering Society, adopts the following declaration of its present plan and policy:

1. Engineering Foundation regards engineering research as the preferred field for its activities.
2. It will select or approve specific researches which it will assist by appropriation of funds or otherwise.
3. It will select for each project the agency, collective or individual, which it deems most effective.
4. It will assume no direct responsibility for the prosecution of any specific research.
5. It will cooperate with the national Engineering Societies and preferably support researches approved by it sponsored by one or more of them.
6. A member of Engineering Foundation, or of its staff, may be an advisory, but not an active, member of any committee or other organization in immediate charge of a research assisted financially by the Foundation. This provision will not be retroactive.
7. Engineering Foundation reserves the right to require from committees or other organizations or individuals assisted, satisfactory progress reports as a condition of continued support.
8. Engineering Foundation will cooperate with the several Founder or other national Engineering Societies in raising funds for the prosecution of approved researches.
9. It will endeavor to prevent conflict or overlap of research effort among the agencies which it supports or assists.
10. It will cooperate in securing information of the state of the art for use of committees of the Founder Societies or other agencies.

Adoption of this plan has placed the impartial and judicial attitude of Engineering Foundation beyond the questions which, without it nevitably would have arisen when the Foundation in future determined allotment and use of large sums.

Under the policy adopted, researches conducted by the Founder Societies will be doubly safeguarded in their selection, since they will have passed independent approval by the board of a Founder Society and by Engineering Foundation. Likewise, collective wisdom will be exercised in the use of funds entrusted to Engineering Foundation and to the Founder Societies.

A project having been thus endorsed, members of the Founder Society advocating it should be effective, directly or through Engineering Foundation, in raising funds or securing other aid by appeal to those who may expect to benefit.

And the time may not be far distant when the intelligence of those who have benefitted from engineering will perceive the advantage to be derived for the Profession, for Industry and for the Public from providing Engineering Foundation so adequately with funds that effort and time now expended in solicitation, with all the incidental annoyances and waste, may be conserved for earlier attainment of benefits sought.

L. B. STILLWELL, Chairman.
ALFRED D. FLINN, Director,
Engineering Foundation

PERSONNEL RESEARCH FEDERATION

Since 1921, the Personnel Research Federation, according to the fourth annual report, has been gaining support and promoting a number of researches. Since 1922 it has issued the Journal of Personnel Research, recognized not only in America but in other countries as well. Doctor Walter V. Bingham, Director of the Federation, is also editor of the *Journal of Personnel Research*. The Federation has 28 member organizations and 62 individual members, widely distributed. Recent additions to this cooperative membership include the Massachusetts Institute of Technology, Division of Industrial Cooperation and Research; Yale University, Department of Administrative Engineering; the Federal Board of Vocational Education. Officers elected for the current year are President, Howard Coonley, member, American Society of Mechanical Engineers, President, Walworth Company, Boston; Vice Presidents, Alfred D. Flinn, Director, Engineering Foundation, New York; William Green, President American Federation of Labor, Washington; Cator Woolford, Retail Credit Company, Atlanta; Secretary, Robert I. Rees, American Telephone and Telegraph Company, New York; Treasurer, Francis H. Sisson, Vice-President, Guaranty Trust Company New York.

American Engineering Standards Committee

NEW LIMIT-GAGE FOR MASS PRODUCTION

To make for the greatest possible output of the highest quality mass production, has become available to all American manufacturers of machinery, vehicles, tools, electrical apparatus and many other lines of product through the standardization of the limit gages just completed by the American Engineering Standards Committee. The limit gages upon which the new standards are based are simple devices for great accuracy in checking dimensions. The preparation of the standards was the work of a committee of twenty-one experts under the chairmanship of Colonel Eugene C. Peck, prominent manufacturer of Cleveland, Ohio; the committee was under the official leadership of The American Society of Mechanial Engineers. Not only industrial groups but the government, through the Army and Navy Departments and Bureau of Standards participated.

UNIFICATION OF WIRE AND SHEET METAL GAGES PROPOSED

The American Engineering Standards Committee has been requested by the Society of Automotive Engineers to take up the unification of wire and sheet metal gage systems in order to arrive at a national standard system of designating the diameters of metal wires and the thicknesses of metal sheets.

A conference of all industrial groups interested in this problem will be called in the near future, to discuss the desirability and

possibility of unifying the various existing gage systems into a consistent national system, or systems.

CAN AMERICAN AND BRITISH SCREW THREADS BE UNIFIED?

A conference of standardization experts is to be held in April to discuss possibilities, and the American Engineering Standards Committee and the National Screw Thread Commission have invited the British Engineering Standards Association to consider the possibility of unifying the American and British screw thread systems.

Both the American and the British systems of screw threads have been the result of a long national development, the basis for the American system having been laid by William Sellers in 1864, and that for the British system by Joseph Whitworth in 1841. The standard threads are called "American (national) standard thread" in this country, and "British Standard Whitworth (BSW) thread" in Great Britain.

A fundamental difference between the two national systems exists, however, and the importance of a possible unification between the two screw thread systems will be obvious if one realizes the innumerable applications of threaded parts to modern manufacture.

Sharon, Pa., Has New Section

Amid considerable enthusiasm manifested by the 225 who were present a new Section was formally organized at Sharon, Pa., at a meeting held on January 5 and the following Officers were elected and the first Section paper presented: W. M. Dann, Chairman, L. H. Hill, Secretary-Treasurer.

An executive committee consisting of the following members was elected: Chairman, W. M. McConahey, C. S. MacCalla, E. B. Clarke, W. J. Harrier and P. E. Cook.

Power Flow in Electrical Machinery was the title of the paper, presented by Joseph Slepian, Westinghouse Electric & Mfg. Co. Extensive discussion followed the address.

Formation of the Sharon Section brings the total number of Institute Sections up to fifty-one.

New Metallurgical Laboratories

The new metallurgical laboratories of the Pittsburgh Experiment Station of the Bureau of Mines, Department of Commerce, will be formally opened on the evening of January 26. Members of the Metallurgical Advisory Board of Carnegie Institute of Technology and the Bureau of Mines will be present. Others prominent in the mining and metallurgical fields are expected to attend.

The new metallurgical laboratories are the outgrowth of an agreement made in 1923 under which Carnegie Institute of Technology appointed an advisory board for its Department of Metallurgy and arranged for cooperative research fellowships in metallurgy at the Pittsburgh Experiment Station of the Bureau of Mines. Under the arrangement, certain problems in the metallurgy of iron and steel formerly conducted at the Northwest Experiment Station of the Bureau of Mines, Seattle, Wash., are being studied at Pittsburgh. In the study of these problems, the well equipped laboratories of Carnegie Institute of Technology will be available to supplement those of the Bureau of Mines.

Monthly Bulletin of the Mexico Section

The Mexico Section of the Institute started to publish at the beginning of 1924 a monthly Bulletin in the Spanish language, containing not only the proceedings of the Section, but also many other articles and technical papers of interest to electrical engineers.

The Bulletin is mailed free of charge to every electrical and mechanical engineer, every light and power company, and many other companies and individuals in the Republic of Mexico; and the Mexico Section is also willing to mail it to Spanish speaking members of the Institute in other countries, without charge, upon receipt of application.

Letters may be addressed to any of the following: Mr. E. F. Lopez, Fresno No. 111, Mexico, D. F., Chairman, and Mr. Hernan Larralde, Isabel LaCatolica 33, Mexico, D. F., Secretary, Mexico Section; Mr. Jorge E. Castro, Apartado Postal 124 Bis, Mexico, D. F., Editor in Chief, and Mr. J. P. Ramirez, Apartado No. 2057, Business Manager, of the Bulletin.

G. E. Review Plans 5-Year Index

An index of articles run in the magazine during the past five years is being planned by the *General Electric Review*. The index will be alphabetically arranged by subject and author, thus facilitating ready reference to articles carried during the years 1920-1925. It will be bound in a durable, heavy, stock paper cover and will be made to sell for a nominal sum. The size of the index will be 8 by 10½ in.—the same as the magazine.

Before starting the work of compiling this information, the *Review* is anxious to secure the comments of libraries and individuals interested in such a publication. It is requested that those who can make use of the index signify their interest in it by writing the magazine at Schenectady, N. Y. If sufficient interest is manifested in the work, it will be started within a few weeks.

National Academy of Sciences Appeals For Research Funds

The National Academy of Sciences announces an appeal to prominent public men to join with the leading scientists of the country in an endeavor to secure greater resources for the research in pure science, claiming that while the United States is leading all nations in industrial science, it is falling behind in pure science research. A special board created by the Academy for the handling of these funds includes Albert A. Michelson, President of the National Academy of Sciences and a Nobel prize winner; Gano Dunn, chairman of the National Research Council; Vernon Kellogg, Permanent secretary for the National Research Council; Elihu Root, Herbert Hoover, Andrew W. Mellon, Charles E. Hughes, John W. Davis, Colonel Edward M. House, Julius Rosenwald, Cameron Forbes, Felix Warburg, Henry S. Pritchett, Doctor Robert Millikan, Foreign secretary of the National Academy of Sciences, Doctor Merriam of Carnegie Institution of Washington, Owen D. Young, Henry M. Robinson, Doctor Simon Flexner of the Rockefeller Institute of Medical Research, Doctor J. J. Carty, Vice-President of the Am. Tel. & Tel. Co. and past-president of the A. I. E. E., Doctor Wm. H. Welch, Director of the School of Hygiene and Public Health, Johns Hopkins University and others of equal prominence.

PERSONAL MENTION

William S. Schmidt will shortly join the Pennsylvania-Ohio Power & Light Company at Youngstown, Ohio. Mr. Schmidt has been connected with the Penn Public Service Corporation for the past few years.

Rene A. Wurgel who has been planning engineer for the Western Electric Company New York City, has accepted a position as Purchasing Engineer with the Holly Pneumatic Systems, Inc., 100 East 45th Street, New York City.

Edgar Kobak has been elected vice-president and director of the McGraw-Hill Company, Inc., acting as publishing head of the McGraw-Hill electrical publications, *Electrical World, Electrical Merchandising, Industrial Engineer, Journal of Electricity and Radio Retailing.*

Frank A. Ketcham will be executive vice-president of the new Graybar Electric Company. Mr. Ketcham has been with the Western Electric Company for the past eighteen years, beginning as a clerk in their Chicago office. Since 1921, he has held the position of general manager of their supply department.

A. W. McLimont has been appointed president of the Winnipeg Electric Company for which he has served as vice-president and general manager for the past eight years. Mr. McLimont was formerly electrical engineer of the First District of the Public Service Commission of New York and has been connected with electric systems in both South America and Mexico.

C. M. Goddard, for thirty-five years secretary of the New England Insurance Exchange, was given a dinner on January 7th by 200 of his associates in the fire insurance field. Mr. Goddard was closely associated with the development of the National Electrical Code retiring from active business on the first of this year.

Theodore H. Dillon, professor of public utility management at Harvard University, has resigned to become manager of the Boston district of the United Fruit Company. Colonel Dillon was for several years professor of electrical engineering at Massachusetts Institute of Technology and is a graduate of West Point, holding a record for distinguished military engineering.

W. H. Sawyer, Fellow of the A. I. E. E. and H. W. Eales, a regional vice-president of the A. I. E. E., sail for Australia on February 2nd to make a report of investigation on the Yallourn brown coal electricity generation scheme and connected power undertakings of the government electricity commission. Their chief mission is to place the benefit of America's electrical experience at the disposal of Australia.

Donald McNicol, Fellow of the A. I. E. E. and last year assistant to the president of the Radio Corporation of America, has been elected president of the Institute of Radio Engineers, taking office at the time of their recent convention held in the Engineering Societies Building January 18-19. Good progress in this specific field of scientific endeavor seems assured both by the success of this, the first full membership convention of the Radio Engineers and in their choice of Mr. McNicol as president for the ensuing year.

William K. Vanderpoel, since January 1, 1916 general superintendent of distribution, of what is now the Electric Department of Public Service Electric and Gas Company has resigned to become vice-president and executive engineer of The Okonite Company and The Okonite-Callender Cable Co., Inc., manufacturers of wire and cable for electric purposes, with factories at Paterson and Passaic, and general offices in New York City. Mr. Vanderpoel came to Public Service in 1907 as superintendent of Distribution for the Newark district, and in 1916 was made general superintendent of distribution. He is a Director of the A. I. E. E. and has served, or is serving on its Executive, Finance, Power, Standards, Edison Medal committees and others.

S. L. Nicholson has recently been elected acting vice-president of the Westinghouse Electric and Manufacturing Company. Mr. Nicholson has been affiliated with the Westinghouse Company since 1898, being appointed sales manager in 1909 and assistant to the vice-president in 1917. He was the first president of the American Association of Electric Motor Manufacturers, now known as the Electric Power Club, assisted in the formation of the American Gear Manufacturers' Association, was chairman of the Power Club, Electric Manufacturers' Club and the Association of American Manufacturers of Electrical Supplies. During 1921, Mr. Nicholson was chairman of the Tariff Committee of the Council and represented the electrical industry on the National Industry Conference Board: is a member of the Electrical Safety Conference, the American Statistical Association and the Bureau of Personnel Research for Carnegie Institute of Technology.

Addresses Wanted

A list of names of members whose mail has been returned by the Postal Authorities is given below, together with the addresses as they now appear on the Institute records. Any member knowing the present address of any of these members is requested to communicate with the Secretary at 33 West 39th St., New York, N. Y.

All members are urged to notify the Institute Headquarters promptly of any change in mailing or business address, thus relieving the member of needless annoyance and also assuring the prompt delivery of Institute mail, the accuracy of our mailing records, and the elimination of unnecessary expense for postage and clerical work.

1.—Geo. B. Coleman, P. O. Box 322, Dayton, Ohio.
2.—Geo. E. Haines, 3538 W. Monroe St., Chicago, Ill.

Obituary

Loyal B. Alden, construction engineer, died on December 13, 1925. Mr. Alden was born in 1870 in Leicester, Addison County, Vermont. He received his engineering education at the Massachusetts Institute of Technology—later taking the student's course in the Construction Department of the General Electric Company. He was connected with the General Electric Company in Baltimore for some years, having been in charge of the construction of a transformer station in Baltimore, built in connection with the McCall's Ferry Plant and the substation of the Baltimore and Ohio Railroad on Park Avenue which furnishes current for running the Belt Line Railroad of the Baltimore & Ohio Railroad Company.

Arthur W. Jones died at his home in Schenectady, December 26, 1925. Mr. Jones was born in Philadelphia in May 1866 and took an electrical engineering course at the Massachusetts Institute of Technology—after graduation he officiated with the Thomson-Houston Company of Lynn, Mass. Several years later became chief engineer of the International Thomson-Houston Company. In 1894 he was sent to Port Elizabeth, South Africa, and as representative of the General Electric Company for that territory, in 1895 accepted a similar position in Melbourne, Australia. Returning to Schenectady in 1905, he served as manager of the railway signal department—being directly connected with the Far East department of the International General Electric Company and having direction over the company's interests in various Oriental Countries.

Otto C. Miller, of the Los Angeles Section of the Institute, died on December 11, 1925, in that city. He was born in Columbus, Texas, on September 12, 1867 and received his education as private student and co-worker with William Lundberg, a Danish mathematician and scientist in Los Angeles. Mr. Miller has been connected with the Los Angeles Gas and Electric Corporation for the past fifteen years as an Electrical Underground Engineer.

Benjamin H. Ryder, a member of the A. I. E. E., died on December 28, 1925. Mr. Ryder's birth place was Hudson, N. Y., where he was born December 3rd, 1878. He received his education in Chicago, becoming connected with the American Steel & Wire Company in Pittsburgh shortly thereafter. Later he was transferred to the Chicago office of the concern, where he remained until the time of his death. Mr Ryder's loss will be felt by his many friends and associates.

Frederick A. Huntress, for many years an official of the Brazilian Traction, Light and Power Company, Ltd., operating in the city of Rio Janeiro and Sao Paulo, Brazil, died January 27th at his apartment, Hotel Somerset, Boston.

Born in Biddeford, Maine, Mr. Huntress' late general and technical education was through Harvard College, from which he graduated in 1891 with the degree of A. B. In 1893, he affiliated himself with the Boston Elevated Railway, doing special work in

generation and distribution of power for them. In 1894 he was identified with the Montreal (Canada) Street Railway Company as assistant to the Electrical Engineer, to return in 1895 to the Boston Elevated Railway as assistant to their master mechanic. In 1896 he was made assistant to the general manager of the Halifax Tramway Light and Power Company, and later became general manager himself in 1898. In 1903, the Worcester Consolidated Street Railway Company chose him as their general manager and he remained with them until his departure from the States to connect with the Rio Janiero Tramway Company of which he was first Vice President at the time of his death. In 1922 he returned from South America to take residence in Lenox, Mass., and has remained in the United States ever since.

Engineering Societies Library

The library is a cooperative activity of the American Institute of Electrical Engineers, the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers and the American Society of Mechanical Engineers. It is administered for these Founder Societies by the United Engineering Society, as a public reference library of engineering and the allied sciences. It contains 150,000 volumes and pamphlets and receives currently most of the important periodicals in its field. It is housed in the Engineering Societies Building, 29 West Thirty-ninth St., New York.

In order to place the resources of the Library at the disposal of those unable to visit it in person, the Library is prepared to furnish lists of references to engineering subjects, copies or translations of articles, and similar assistance. Charges sufficient to cover the cost of this work are made.

The Library maintains a collection of modern technical books which may be rented by members residing in North America. A rental of five cents a day, plus transportation, is charged.

The Director of the Library will gladly give information concerning charges for the various kinds of service to those interested. In asking for information, letters should be made as definite as possible, so that the investigator may understand clearly what is desired.

The library is open from 9 a. m. to 10 p. m. on all week days except holidays throughout the year except during July and August when the hours are 9 a. m. to 5 p. m.

BOOK NOTICES DECEMBER 1-31, 1925

Unless otherwise specified, books in this list have been presented by the publishers. The Society does not assume responsibility for any statement made; these are taken from the preface or the text of the book.

All books listed may be consulted in the Engineering Societies Library.

AUFGABENSAMMLUNG UBER DIE GLIECHSTROMMASCHINE MIT LOSUNGEN.

By Fr. Sallinger. Ber. u. Lpz., Walter de Gruyter & Co., 1925. 108 pp., diagrs., 6 x 4 in., cloth. 1,25 gm.

This, the third volume of Professor Sallinger's concise textbook on continuous-current machines, is devoted to examples of the application of the formulas and rules given in the previous volumes. These examples are worked out in detail and illustrate clearly the practical use of the theory.

ELEMENTS OF INTERNAL-COMBUSTION ENGINEERING.

By Telford Petrie. Lond. & N. Y., Longmans, Green & Co., 1925. 236 pp., diagrs., 9 x 6 in., cloth. $3.75.

The various types of gas and oil engines, their cycles of operation, ideal cycles and their functions, the thermodynamics of the gas engine and the other theoretical considerations of these engines are discussed. The work is confined to theory and does not discuss practical details of design.

L'EMPLOI DES INDICATEURS COLORES; LA DETERMINATION COLORIMETRIQUE DE LA CONCENTRATION DES IONS HYDROGENE.

By I. M. Kolthoff. Translated from the 3rd German edition by Edmond Vellinger. Paris, Gauthier-Villars et cie, 1926. 250 pp., diagrs., tables, 9 x 6 in., paper. 50 fr.

The simplicity and rapidity of the color indicator method of measuring the concentration of hydrogen ions in aqueous solutions have led to a wide extension of its use for this important purpose. The author of this book gives a survey of the various methods used and studies their application under a wide variety of conditions, so that the work is of value to all who utilize indicators in chemical or biological work.

HEALTH MAINTENANCE IN INDUSTRY.

By J. D. Hackett. Chicago & N. Y., A. W. Shaw Co., 1925. 488 pp., diagrs., tables, 9 x 6 in., fabrikoid. $6.00.

Increasing appreciation of the relation between the health of workmen and their efficiency has led to the establishment of medical departments in many plants. This book gives an account of the organization of such a department and of the ways in which it may aid production. The subject is treated simply, from the point of view of the plant manager, who is responsible for the direction of the activities of the department, but has no medical training.

HEPHAESTUS; OR, THE SOUL OF THE MACHINE.

By E. E. Fournier D'Albe. N. Y., E. P. Dutton & Co., 1925. 76 pp., 7 x 5 in., cloth. $1.00.

An interesting, original study of the relations between man and his machines. How the age of machinery has come about and what influence machinery will eventually have on society is explained in striking fashion in this little book.

INDUSTRIAL ELECTRICITY, Part 2.

By Chester L. Dawes. N. Y., McGraw-Hill Co., 1925. (Electrical Engineering Texts) 480 pp., illus., diagrs., 8 x 6 in., cloth. $2.75.

D-c. machinery having been covered in the first volume of this text, the present book takes up alternators. The fundamental principles and the simple laws of alternating currents and a-c. circuits fill the first chapters. The construction and operating characteristics of a-c. generators and motors are then discussed and analyzed, and the relations of their characteristics to their industrial uses considered. The last three chapters are devoted to general industrial applications of electricity, such as illumination, electron emission and radio communication.

INDUSTRIAL FURNACES, Vol. 2.

By W. Trinks. N. Y., John Wiley & Sons, 1925. 405 pp., illus., diagrs., tables, 9 x 6 in., cloth. $5.50.

While the first volume of this important work was largely theoretical and of particular interest to the designer, this volume is primarily devoted to practise and makes its appeal to those who select, install and operate furnace equipment. The author discusses fuels, combustion devices, temperature control, atmosphere control and labor-saving devices, compares various fuels and types of furnaces, and offers advice on their selection. Electric furnaces are included in the discussion.

L'INDUSTRIE CHIMIQUE DES BOIS; leurs dérivés et extraits industriels.

By P. Dumesny and J. Noyer. Paris, Gauthier-Villars & cie., [1925.] 432 pp., illus., diagrs., 10 x 7 in., paper. 50 fr.

In writing this book, the authors have had in mind the needs of practical men and have given special attention to industrial methods. The book is divided into two sections. The first opens with a review of the chemical composition of wood and the properties of the products obtained by carbonization and by distillation. The principal processes of carbonization are then described. A chapter is devoted to the manufacture of acetic acid, methyl alcohol and the acetates, and another to secondary products of wood distillation. The second section treats of the extraction and use of tannins.

JAHRBUCH DER BRENNKRAFTTECHNISCHEN GESELLSCHAFT.
E. V. 1924. V. 5. Halle (Saale), Wilhelm Knapp, 1925.
112 pp., illus., diagrs., 11 x 8 in., paper. 7,80 gm.

The fifth yearbook of the Society includes a report of the proceedings at the annual meeting of December, 1924, and several of the papers read at that time. These include addresses on "Internal Combustion Engines, Especially Diesel Locomotives for Railways" by H. Nordmann; "Ignition Phenomena in Gas Engines" by J. Tausz; "Large Diesel Engines for Ships" by R. Dreves; "Raising the Power of Gas Engines through Pre-compression by Blowers, and the Use of Exhaust Gases in Turbines to Drive these Blowers" by W. G. Noack; "The Principles of High-Speed Semi-Diesel Engines" by Dr. Büchner; and "On the Numerical Expression of the Idea of the Quality Calorie" by W. Ostwald.

DIE LEISTUNG DES DREHSTROMOFENS.
By J. Wotschke. Berlin, Julius Springer, 1925. 70 pp., diagrs., tables, 9 x 6 in., paper. 5,10 g. m.

Books on the electric furnace are not numerous, and in those that exist less attention is paid to the needs of the electrical engineer than of the chemist and metallurgist. In this book the author attempts to meet electrical requirements by a discussion of the electrical theory and of the electrical factors that make for the greatest efficiency. He calls attention to opportunities for research in this field.

NIAGARA IN POLITICS; a Critical Account of the Ontario Hydro-Electric Commission.
By James Mavor. N. Y., E. P. Dutton & Co., 1925. 255 pp., 8 x 5 in., cloth. $2.00.

Professor Mavor's work is an indictment of the Hydroelectric Power Commission of Ontario, which he condemns on grounds of both public policy and of economic advantage.

PATENTS; Law and Practice. 3rd edition. 1924. 56 pp.
TRADE-MARKS, TRADE NAMES, UNFAIR COMPETITION. 4th edition. 1925. 48 pp.
N. Y., Richards & Geier, 277 Broadway. 9 x 6 in., paper. Gratis.

These pamphlets provide a convenient summary of the patent and trade-mark laws of the principal countries of the world. They are intended to give laymen the more important facts, as a guide in meeting the problems that arise most frequently.

POWER PLANT LUBRICATION.
By William Farrand Osborne. N. Y., McGraw-Hill Book Co., 1925. 275 pp., illus., diagrs., tables, 8 x 6 in., cloth. $3.00.

A concise account of the properties of lubricants and of the methods of buying, testing and using them on various classes of power-plant machinery. Intended for operating engineers.

PRACTICAL MARINE DIESEL ENGINEERING.
By Louis R. Ford. N. Y., Simmons-Boardman Publ. Co., 1925. 512 pp., illus., diagrs., 9 x 6 in., fabrikoid. $7.50.

Discusses the theoretical principles of the Diesel engine, the construction of its various stationary and moving parts, and its accessories. Descriptions of typical commercial engines of various types are given, and a large part of the book is devoted to the operation of Diesel engines and the derangements likely to occur. The book is intended for practical enginemen, especially for the marine steam engineers who wish to operate these engines.

STAUB-EXPLOSIONEN.
By Paul Beyersdorfer. Dresden u. Lpz., Theodor Steinkopff, 1925. 125 pp., illus., tables, 9 x 6 in., paper. 5,50 mk.

A summary of our knowledge of dust explosions. Discusses their character, the dangerous properties of dust, effects of heat and static electricity, the action of explosions and methods of prevention. The book is intended to present the situation in a form convenient for consultation by those engaged in dusty industries.

TAGUNG DES ALLGEMEINEN VERBANDES DER DEUTSCHEN DAMPFKESSEL-UBERWACHUNGSVEREINE.
April 1925, Karlsruhe. Berlin, VDI Verlag, 1925. 132 pp., illus., diagrs., plates, 12 x 9 in., paper. 16,-gm.

The proceedings contain reports and discussions upon a number of important matters relating to boiler operation. Among these are the tension in heavy boiler plates; the influence of temperature, shape of test-piece and speed of testing upon notched bar tests; American rules for water purifier operation; accessories for high-pressure boilers; autogenous and electric welding for boiler parts; the high-pressure boiler. Statistics of boilers are appended.

USINES HYDROELECTRIQUES.
By Charles L. Duval and J. L. Routin. Paris, J. B. Baillière et fils, 1925. 512 pp., illus., diagrs., 9 x 6 in., paper. 60 fr.

A general textbook on hydroelectric power plants. The authors give a description of these plants as a whole, showing the various apparatus used and explaining the reasons that have led to its choice in each case, its dimensions and its use. Both hydraulic and electric features are discussed, but details of the construction of the apparatus are omitted.

The book is based on the course at the Ecole Supérieure d'Electricité.

Book Review

SUPERPOWER: ITS GENESIS AND FUTURE.
William S. Murray, New York. McGraw-Hill Book Co. 1925. 238 pp., illus., 6 by 9 in. cloth. $3.00.

In this book Mr. Murray, the father of Superpower, tells in an intimate and pleasingly spontaneous way the complete story of Superpower and its possibilities, from the time he first conceived the idea up to its present development, and its future possibilities. It is pointed out that the name, Superpower, has been frequently misunderstood or misrepresented whereas its real meaning is the physical interconnection of all generating plants within certain zones in order to take advantage of diversity economy and thereby greatly reduce reserve equipment and avail interruptions to service from breakdowns. The subject is discussed from a wide variety of aspects and in non-technical language and points out why this movement, already under way, cannot but eventually furnish more adequate and economic means of power and transportation, which are the two essential elements upon which the industry and prosperity of the nation depend.

Past Section and Branch Meetings

SECTION MEETINGS

Akron

Sleeve Bearings Versus Anti-Friction Bearings, by J. L. Brown, H. D. Else and L. E. Erickson. A dinner preceded the meeting. Joint with A. S. M. E. December 18. Attendance 54.

Baltimore

Dielectrics and Insulation, by J. B. Whitehead, Johns Hopkins University. October 16. Attendance 85.

Holtwood Steam Station, by V. E. Alden, Consolidated Gas, Electric Light and Power Co.

Recent Experience with Transmission System of Pennsylvania Water Power Company, by A. F. Bang and E. Hansson, Pennsylvania Water and Power Co., and

Hydraulic Maintenance at Holtwood Plant, by T. C. Stabley. November 21. Attendance 280.

Electric Refrigeration, by Mr. Twilley, The Kelvinator Co., and

Illumination, by J. C. Fisher, Consolidated Gas and Electric Co. Ladies Night. December 18. Attendance 140.

Chicago

Power Flow in Electrical Machines, by Joseph Slepian, Westinghouse Elec. & Mfg. Co. January 11. Attendance 210.

Cleveland

Railroad Electrification—Present and Future, by N. W. Storer, Westinghouse Elec. & Mfg. Co. Illustrated with slides. November 20. Attendance 91.

Tendencies in Power Development and Transmission, by Robert Treat. Dean C. Ober, Cleveland Electric Illu-

minating Co., showed pictures of new apparatus used in his company's high-tension lines. December 17. Attendance 87.

Denver

Public Utility Securities and Financing, by J. E. Loiseau, Public Service Company. December 18. Attendance 27.

Detroit-Ann Arbor

Recent Developments in Heavy Electric Traction, by N. W. Storer, Westinghouse Elec. & Mfg. Co. A motion picture, entitled "Electrified Travelogue," preceded the talk. November 17. Attendance 100.

Polarization of Radio Waves, by E. F. W. Alexanderson, Radio Corporation of America. A motion picture, entitled "The Story of the Storage Battery," preceded the talk. December 4. Attendance 450.

Erie

Radio, by P. J. Larsen, Radio Corporation of America. The lecture was illustrated with moving pictures and the latest a-c. receiving sets and loud speakers were demonstrated. December 15. Attendance 255.

Fort Wayne

Lightning, by F. W. Peek, Jr. December 15. Attendance 80.

Electrons and Hobbies, by W. R. Whitney, General Electric Co. January 11. Attendance 150.

Ithaca

Electrical Transmission of Speech, Music and Noise, by Harvey Fletcher, Bell Telephone System Laboratories. The lecture was demonstrated with special wave-filter apparatus. December 7. Attendance 200.

Los Angeles

Electrolysis, by I. D. Van Giesen, Los Angeles Bureau of Water Works and Supply. Illustrated with slides. A dinner preceded the meeting, at which talks were given by E. A. Bailie, Los Angeles Engineering Dept., and J. E. Philips, Los Angeles Water Distribution Dept., on "The Proposed Colorado River, Los Angeles Aqueduct" and "The Existing Local Water Situation in Los Angeles," respectively. January 5. Attendance 134.

Lynn

The Quest of the Unknown, by H. B. Smith, Worcester Polytechnic Institute. Illustrated with slides. December 17. Attendance 50.

Mexico

Annual Banquet. October 24. Attendance 43.

Parasite Currents in the Bearings of A-C Machinery, by A. Cornejo.

Operation of Distributing Systems of Electrical Energy, by J. V. Crotte. December 3. Attendance 24.

Milwaukee

Design and Construction of the New Riverside Pumping Station, by Ralph Cahill. December 16. Attendance 60.

Minnesota

Communication Service on Railroads, by J. C. Rankine, Great Northern Railway Co. The talk was demonstrated by special telegraph equipment and apparatus. Motion pictures taken along the Great Northern Railway were shown. January 4. Attendance 37.

Nebraska

Automatic Stations, by C. W. Place, General Electric Co. Joint meeting with Engineers Club. December 14. Attendance 78.

Niagara Frontier

The Klydonograph, by J. F. Peters, Westinghouse Elec. & Mfg. Co. January 8. Attendance 35.

Philadelphia

High-Quality Phonographic Reproduction, by J. P. Maxfield, Bell Telephone Laboratories, Inc. December 14. Attendance 315.

Pittsburgh

Breakdown of Solid Dielectrics, by Vladimir Karapetoff, Cornell University. December 8. Attendance 348.

Pittsfield

Electrical Measurements in Medical Diagnosis, by H. B. Williams, Columbia University. December 15. Attendance 260.

Recent Theories and Developments in the Science of Radio, by E. F. W. Alexanderson, Radio Corporation of America. January 5. Attendance 375.

Portland

Baker River Hydroelectric Development, by L. M. Robinson, Stone and Webster, Inc. December 9. Attendance 81.

Providence

Costs of Operation of Isolated Power Plants, by R. L. Yates, Skinner Engine Co. Joint meeting with A. S. M. E., Providence Engineering Society and Illuminating Engineering Society. January 5. Attendance 100.

Rochester

Development and Research Work of the Bell Telephone Laboratories, by S. P. Grace, Bell Telephone Laboratories. December 4. Attendance 300.

San Francisco

Symposium on Power-Distribution Systems, by S. J. Lisberger, G. H. Hager, L. J. Moore and D. K. Blake. A dinner preceded the meeting. October 2. Attendance 190.

Oil Circuit Breakers, by J. S. Thompson, Pacific Elec. Mfg. Co. A dinner preceded the meeting. October 30. Attendance 215.

Some Engineering Aspects of the Telephone Building, by C. W. Burkett, G. M. Simonson and L. W. Whitton. December 11. Attendance 250.

Spokane

Reflections on Power Factor, by W. T. Ryan, Washington Water Power Co. December 18. Attendance 18.

Springfield

Storage Batteries, by R. D. Harrington, Electric Storage Battery Co. December 21. Attendance 47.

Syracuse

Hydroelectric Developments in Japan, by S. Q. Hayes, Westinghouse Electric & Mfg. Co. Illustrated with slides. December 14. Attendance 100.

Toronto

The Chronograph Method of Speed Measurement, by P. A. Borden, Hydro-Electric Power Commission of Ontario. Illustrated. Mr. F. K. D'Alton also gave a short talk on this same subject. Two moving pictures on the "Wizardy of Electricity" were shown by Mr. Johnston of the Canadian General Electric Co. December 18. Attendance 45.

Urbana

A Message from Herbert Hoover, by W. A. Durgin, Commonwealth Edison Co. December 9. Attendance 44.

Mechanical Force between Electric Circuits, by R. E. Doherty, General Electric Co. December 17. Attendance 108.

Worcester

Lightning and Other Transients on Transmission Lines, by F. W. Peek, Jr., General Electric Co. Illustrated with slides and moving pictures. December 10. Attendance 50.

BRANCH MEETINGS

University of Alabama

The meeting was devoted to the showing of moving pictures. December 15. Attendance 36.

University of Arizona

Railroad Electrification, by Charles Dunn, and

Electrification of Ships, by Leo Wolfson. November 7. Attendance 13.

Electrically Driven Vehicles, by Wm. R. Brownlee, and

Electric Welding, by E. Brooks. November 14. Attendance 14.

The Electron Theory, by T. E. Davis. November 21. Attendance 16.

Opportunities in the Telephone Industry. A motion picture, entitled "Rolling Steel by Electricity," was shown. December 5. Attendance 23.

The Big Creek Project, by Jos. Denzer. Moving picture, entitled "Speeding Up the Deep-Sea Cables," was shown. December 12. Attendance 20.

A motion picture, entitled "Beyond the Microscope," was shown. December 19. Attendance 17.

Brooklyn Polytechnic Institute

Engineering Features of Long-Distance Telephony, by C. S. Hawkins, American Telephone & Telegraph Co. Illustrated with slides, and

High-Frequency Radio Oscillations, by B. Adler, student. December 16. Attendance 55.

Carnegie Institute of Technology

Electrification of the Norfolk and Western Railroad, by Thomas Wurts, Westinghouse Electric & Mfg. Co. December 2. Attendance 34.

Case School of Applied Science

Business Meeting. The following officers were elected: Chairman, C. A. Baldwin; Vice-Chairman, E. W. Drexler; Secretary, A. B. Anderson; Treasurer, J. C. Erickson. October 19. Attendance 30.

University of Cincinnati

Relation of the Technical Journal to the Industry, by Earl W. Whitehorne, Commercial Editor of *Electrical World*. December 3. Attendance 59.

University of Denver

Business Meeting. January 8. Attendance 15.

Georgia School of Technology

Business Meeting. December 15. Attendance 40.

Inspection trip to Boulevard Sub-Station of the Georgia Railway and Power Company. December 17. Attendance 35.

University of Idaho

Film, entitled "Pillars of Salt," was shown. December 8. Attendance 24.

State University of Iowa

A film, entitled "The Story of an Electric Meter," was shown. December 18. Attendance 50.

Unipolar Generators, by Herman Wacker, and

Electrons and Ions, by L. A. Ware. January 6. Attendance 44.

Kansas State College

Opportunities of the Graduate, by Professor C. E. Reid. December 14. Attendance 83.

Lehigh University

Making the Most of Opportunities, by H. P. Liversidge, Philadelphia Electric Co., and

Automatic Train Control, by O. M. Corson, student. December 17. Attendance 89

Lewis Institute of Technology

Business Meeting. December 10. Attendance 11.

Marquette University

Picking a Job, by F. J. Mayer, Wisconsin Telephone Co. October 15. Attendance 29.

Super-Power, by G. G. Post, Milwaukee Electric Railway & Light Co. November 19. Attendance 28.

Massachusetts Institute of Technology

The M. I. T. Power System, by Theodore Taylor, student. Illustrated with slides. December 15. Attendance 18.

Inspection trip to the Cambridge Plant of the Simplex Wire and Cable Company. December 16. Attendance 5.

University of Michigan

Smoker. December 9. Attendance 65.

School of Engineering of Milwaukee

Industrial Management, by E. E. Brinkman, Holeproof Hosiery Company. January 7. Attendance 28.

Missouri School of Mines and Metallurgy

A general discussion on motor windings, synchronous motors, advantages of their use, and power transmissions took place. January 7. Attendance 10.

Montana State College

Lightning Generators, by Sam Thompson, and

Advantages of Electric Traction, by Rudolph Scovil. December 14. Attendance 159.

College of the City of New York

What the Designing Engineer Has to Do in Practise, by E. S. Henningsen, General Electric Co. January 14. Attendance 24.

University of North Carolina

A Supersensitive Microphone and Its Application to Surgery, by J. F. Clemenger, student. December 4. Attendance 26.

University of North Dakota

Asbestos, by H. G. Thinnes, Johns-Manville, Inc. Demonstrated. A motion picture, entitled "The Story of Asbestos," was shown. Joint meeting with A. S. M. E. December 14. Attendance 5.

Northeastern University

The Work of a Public-Utility Electrical Laboratory, by H. C. Hamilton, Edison Electric Illuminating Co. Illustrated with slides. December 30. Attendance 34.

University of Notre Dame

The Theory of Electricity, by Malcolm Knaus, and

The Fourth Dimension, by Dr. J. A. Caparo. December 9. Attendance 37.

Oklahoma Agricultural and Mechanical College

Two moving pictures, entitled "Electrified Travelogues" and "The King of the Rails," were shown. December 17. Attendance 48.

University of Oklahoma

Three moving pictures, entitled respectively, "King of the Rails," "Big Deeds" and "The Manufacture of Paper," were shown. December 10. Attendance 107.

University of Pittsburgh

Transmission Design, by T. E. Baum, student,

"B"-Battery Eliminator, by N. Orr, student, and

Photo-Electric Cells, by W. D. Carothers, student. December 4. Attendance 22.

The Measurement of Earth Currents, by J. A. Balla, student, and

The Allegheny Bridge Problem, by Chas. M. Reppert, Dept. of Public Works, and V. R. Covell, Bureau of Bridges. December 10. Attendance 25.

The Transmission of Vision and Radio Broadcasting, by H. I. Metz, student. December 17. Attendance 28.

Purdue University

Shaft Behavior, by Dr. G. E. Newkirk, General Electric Co. Joint meeting with A. S. M. E. December 17. Attendance 60.

Rensselaer Polytechnic Institute

What We can Learn from Technical Education in Europe, by C. E. Wickenden, Society for the Promotion of Engineering Education. December 9. Attendance 385.

Rhode Island State College

A moving picture, entitled "From Mine to Consumer," was shown. January 7. Attendance 27.

Rose Polytechnic Institute

The Student Course with the Westinghouse Company, by R. H. Bolin, Westinghouse Electric & Mfg. Co. January 6. Attendance 43.

Rutgers University

The Giant Power System was the title of a debate held at this meeting. December 14. Attendance 24.

A moving picture, entitled "The Story of Copper from Mine to Consumer," was shown. January 11. Attendance 105.

South Dakota State School of Mines

Business Meeting. December 16. Attendance 12.

Business Meeting. January 8. Attendance 18.

University of South Dakota

Business Meeting. October 13. Attendance 15.

What is Matter? by M. Nelles, and

Production of High-Frequency Oscillations, by R. Brackett. November 10. Attendance 9.

Progress of Science, by Dr. Millikan, was read by A. Muchow, and

Wind-Mill Electric Power for the Farm, by W. Doohen. December 8. Attendance 9.

Swarthmore College

The Steel Industry, by Mr. Munson, Atlantic Steel Co. January 7. Attendance 40.

Syracuse University

A-C Railway Electrification, by C. R. Fugill. December 2. Attendance 20.

Lightning Arresters, by R. M. Kelly. December 9. Attendance 18.

Types of Relays and Their Application, by W. H. Lawrence. December 16. Attendance 19.

Texas Agricultural and Mechanical College

Two moving pictures, entitled "Manufacture of Paper" and "Wireless Wizardy," were shown. January 8. Attendance 71.

Washington University

Inspection trip to United Railway Company's Two-Unit Automatic Substation. November 27. Attendance 35.

The Engineering Profession, by Mr. Trescott, Commercial Electric Supply Co. December 3. Attendance 28.

University of Washington

Products of the Northwest, by R. W. Frame, Kenworth Motor Truck Co., and

The Development of the Railroad, by G. T. Reid, Northern Pacific Railroad Co. December 2. Attendance 125.

University of Wisconsin

The Panama Exposition, by Professor C. M. Jansky. Illustrated with slides. December 15. Attendance 64.

Engineering Societies Employment Service

Under joint management of the national societies of Civil, Mining, Mechanical and Electrical Engineers cooperating with the Western Society of Engineers. The service is available only to their membership, and is maintained as a cooperative bureau by contributions from the societies and their individual members who are directly benefited.

Offices:—33 West 39th St., New York, N. Y.,—W. V. Brown, Manager.
53 West Jackson Blv'de., Room 1736, Chicago, Ill., A. K. Krauser, Manager.

MEN AVAILABLE.—Brief announcements will be published without charge but will not be repeated except upon requests received after an interval of one month. Names and records will remain in the active files of the bureau for a period of three months and are renewable upon request. Notices for this Department should be addressed to ***EMPLOYMENT SERVICE, 33 West 39th Street, New York City,*** *and should be received prior to the 15th of the month.*

OPPORTUNITIES.—A Bulletin of engineering positions available is published weekly and is available to members of the Societies concerned at a subscription rate of $3 per quarter, or $10 per annum, payable in advance. Positions not filled promptly as a result of publication in the Bulletin may be announced herein, as formerly.

VOLUNTARY CONTRIBUTIONS.—Members obtaining positions through the medium of this service are invited to cooperate with the Societies in the financing of the work by nominal contributions made within thirty days after placement, on the basis of $10 for all positions paying a salary of $2000 or less per annum; $10 plus one per cent of all amounts in excess of $2000 per annum; temporary positions (of one month or less) three per cent of total salary received. The income contributed by the members, together with the finances appropriated by the four societies named above, will it is hoped, be sufficient not only to maintain, but to increase and extend the service.

REPLIES TO ANNOUNCEMENTS.—Replies to announcements published herein or in the Bulletin, should be addressed to the key number indicated in each case, with a two cent stamp attached for reforwarding, and forwarded to the Employment Service as above. Replies received by the bureau after the positions to which they refer have been filled will not be forwarded.

POSITIONS OPEN

DESIGNER, for manufacturing purposes of such equipment as air break switches, gang operated disconnect switches, bus supports, etc. Experience in simple station operation, design of substations, etc., does not qualify a man for this position. Experience in the actual design and manufacture of the class of equipment described essential. Location, Pennsylvania. R-8118-C.

ENGINEER, experienced in selling industrial electric heating furnaces, for manufacturing concern. Apply by letter stating age, experience and education. Location, Pennsylvania. R-8328-C.

ENGINEER, with experience in design and installation of power station switching equipment. Must be able to supervise and make schematic diagrams of station layout drawings. This is not a drafting job, but requires design ability. Permanent. Opportunity. Apply by letter. Location, Pennsylvania. R-8530-C.

ELECTRICAL ENGINEER, particularly interested and experienced in relay and breaker applications and protection problems on larger power systems. Location, Pennsylvania. R-8506.

ELECTRICAL ENGINEER, experienced in design and calculation of small high tension transformers both closed and open core type. Salary $4000-$5000 a year. Location, New York. R-8346.

ENGINEER, to develop new grinding machines line, especially versed in electrical and hydraulic application. Must have had practical shop training and particularly a thorough scientific and technical education. Apply by letter. Location, Ohio. R-8396-C.

MEN AVAILABLE

GRADUATE ELECTRICAL ENGINEER, age 25, married, desires position with electrical manufacturer or public utility company. Westinghouse experience. Location, East or Middle-west. B-9508.

ELECTRICAL ENGINEER, age 37, college graduate, eighteen years' experience, G. E. test course, system operation, operation, maintenance, construction, design of steam and hydroelectric plants and substations. Just completed three year connection involving design, erection and operation of large high head hydro electric plant. Desires permanent position. Available now. A-895.

ELECTRICAL ENGINEER, 26, six years iron and steel works electrical plant, installation, layout and maintenance both A. C. and D. C., three years manufacturing works, test, design and construction of industrial electrical plant, two years oil fields electrical construction engineer. Desires position either construction or maintenance of power plant, factory, oil fields or iron and steel works. C-8625.

EDITOR OR STATISTICAL ENGINEER, general scientific and electrical engineering training, including two years' post graduate study. Broad experience writing, editing magazine articles, newspaper articles, booklets, books, advertising literature, etc. Thorough knowledge printing. Experience statistical work, sales promotion, business administration, business efficiency methods as assistant to prominent executive large corporation. Location, New York City, Chicago, or Boston. C-549.

ELECTRICAL ENGINEER, age 28, single, technical graduate, desires position with manufacturer electrical apparatus. Five years' experience with engineering department of large company manufacturing industrial control equipment. A little sales experience. Minimum salary $2500. Available on reasonable notice. B-6274.

ELECTRICAL-MECHANICAL ENGINEER, age 37, married, M. E. and E. E. degrees, experienced in design, installation, operation, rehabilitation of hydroelectric and steam power plants, automatic and manual substations, transmission lines underground and overhead, diversified industrial experience in sugar mills, paper mills, mining (gold and coal), public utility, marine engineering and machine shop manufacturing processes. Location anywhere, United States or Canada. B-7944

MECHANICAL ENGINEER, age 32, single, nine years' experience in electrical and mechanical engineering. Electric lighting and power distribution, motors and control, for industrial use. Design of boiler plants, heating and piping. Machinery layouts for plants. Can report at once. Northern part of United States preferred B-3103.

ELECTRICAL ENGINEERING GRADUATE, 1917, age 29, single, desires construction, operation or maintenance with public utility, or consulting engineer; design, research, teaching also considered. Two years Westinghouse student and tester. Some radio, electrical drafting and repair work. Now in fifth year as assistant in E. E. in large Middlewest state university teaching design and power plant economics. M. S. degree 1925. Available in June. Salary $200 per month. B-2758.

ELECTRICAL ENGINEER, age 27, research, in charge of electrical testing, three years chief draftsman; inventive, tactful. Desires responsible position with manufacturing concern. Greater New York preferred. Best references. At present employed. Available on two weeks' notice. B-7270.

MANAGER - GENERAL SUPERINTENDENT-SALES ENGINEER, age 44, unmarried, degree Ph. B in E. E., twelve years with Westinghouse, ten years in utility field. Design, construction, operation four utilities in United States, Alaska, British Columbia. Available at once. B-6910.

MANUFACTURERS' REPRESENTATIVE, located in Sydney, N. S. W., Australia, desires additional agencies for American products of electrical and mechanical nature. Technical training, experience, knowledge of conditions. C-798.

ELECTRICAL ENGINEER, age 27, married, 1923 graduate of University of Washington, hydroelectric experience; nineteen months General Electric Test. Desires to locate on Pacific Coast, position leading to executive responsibility with power company, industrial concern, or large distributor of electrical equipment. Available on short notice. C-742.

EXECUTIVE, age 43, married, thoroughly competent to take charge of office, plant or factory. Many years actual experience in organization, personnel management, valuation and appraisal, installations and supervision, office management, correspondent and special confidential investigations. Available at once. Location, New York or New Jersey. C-521.

EXECUTIVE ENGINEER, age 26, desires to change his position. Has had four years' experience as assistant superintendent and superintendent for various manufacturers making electrical, mechanical, and electro-mechanical devices. Work consisted of time studies, production control, cost analysis, cost forecasts, general factory supervision, etc. Graduate electrical engineer. B-5435.

ELECTRICAL ENGINEER with wide experience in developing intricate electro mechanical and structural problems. College graduate 1910, M. E. and E. E. degrees. Fifteen years' experience here and abroad. Age 40. Location preferred, New York City. A-165.

ELECTRICAL ENGINEER, university graduate, age 28, married, one year testing course, four years experience in construction and design of railway substations, outdoor stations and large hydro and steam power plants. Efficient worker. Desires position as assistant engineer or designer or resident engineer. Available on three weeks' notice. C-792.

ELECTRICAL ENGINEER OR SUPERINTENDENT, age 34, married, eleven years' experience power plant construction, operation and maintenance of same, on steam and hydro, including electric railway, substations, power distribution, transmission. Broad experience on industrial electrifications. Can make estimates and lay-out work. Desires connection with power or engineering company. Available February 15th. C-761.

TECHNICAL GRADUATE, class 1911, age 36, married, desires position as manager of small electric light plant. Have operated my own plant until it was purchased by a large corporation. Bought this plant when it was on the verge of failure and unaided put it on a good paying basis in five years. C-738.

GRADUATE ELECTRICAL ENGINEER, three years' experience in laboratory, testing and designing of steam and gas-electric power plants, including commercial work in responsible position. Can speak and write Spanish, German, French, Russian, Norwegian. Willing to go abroad. Available on two weeks' notice. C-503.

TEACHER OF E. E., young man with extensive training and broad experience desires position. M. S. degree from Cornell University. Practical experience at Westinghouse and other places. Teacher in university for five years, in charge of department two years. Successful as manager. Well liked by students and associates. Good references. B-4968.

ASSISTANT ELECTRICAL ENGINEER, for consulting engineer, public utility or manufacturer. Technical graduate, single, 25, four years' electrical power plant and manufacturing experience before entering college, last two years assistant engineer large public utility in charge electrolysis mitigation, factory inspection electrical equipment, general testing, associated in general design and research. Two weeks' notice. Location immaterial. Salary $165.00. B-9045.

ELECTRICAL ENGINEER, age 39, married, sixteen years' experience supervision design, installation, maintenance, operation nearly all kinds electrical apparatus on over seven thousand miles of railroad, including lighting of all kinds, motor installations, overhead, underground distribution and transmission, submarine cables, building wiring, power plant electrical equipment, industrial high tension substations, meter surveys, industrial trucks. B-9772

YOUNG MAN GRADUATING IN JUNE from M. I. T. in electrical engineering wishes position. Has spent summers in public utility work, both construction and office. Has done graduate work in central stations and distribution at M. I. T. Prominent in undergraduate activities. Location, East. C-803.

MEMBERSHIP — Applications, Elections, Transfers, Etc.

ASSOCIATES ELECTED JANUARY 15, 1926

ALBER, GROVER F., Primary Meter Inspector, The Detroit Edison Co., 2000 Second Ave., Detroit, Mich.

*ALEXANDER, DONALD FORD, Electrical Design Engineer, Westinghouse Elec. & Mfg. Co., East Pittsburgh; res., Wilkinsburg, Pa.

*ALIFANO, ANTONIE, Senior Engineering Student, Brooklyn Polytechnic Institute, 85 Livingston St., Brooklyn; res., Ridgewood, Queens, N. Y.

*APPLETON, WILLIAM EDGAR, Electrical Dept., Gary Heat, Light & Water Co., Gary, Ind.

ARNOLD, GUY WALKER, Electrical Engineer, Canadian Westinghouse Co., Ltd., Hamilton, Ont., Can.

ASHLINE, ROBERT, Asst. to Head Dept. Electrolysis Mitigation, City of Los Angeles, 207 S. Broadway, Los Angeles; for mail, Inglewood, Calif.

AVERY, ARTHUR BENJAMIN Jr., Student & Assistant, University of Arkansas, University Station, Fayetteville, Ark.

*AYRES, EDMUND DALE, Engineer, Jackson & Moreland, 31 St. James Ave., Boston, Mass.

*AYRES, FRANK, Student, The Southern Sierras Power Co., Riverside; res., Highgrove, Calif.

BABCOCK, GERHARDT M., Electrician, Los Angeles Gas & Elec. Corp., Los Angeles, Calif.

*BAILEY, CORNELIUS OLIVER, Radiologist, 912-14 Medical Arts Bldg., Dallas, Texas.

*BAKER, ACKLAND JAMES, Lakeside, Ont., Can.

BARSDORF, LEONARD WILLIAM, Switchboard & Meter Engineer, General Electric Co., Magnet House, Kingsway, London, Eng.

BATTISTA, LOUIS M., Service & Inspection Work, Socony Burner Corp., 40 Franklin St., So. Norwalk, Conn.

*BATY, LAURENCE EDWIN, Meter Tester, The Topeka Edison Co., 12th & Jackson Sts., Topeka, Kans.

*BAUMAN, HAROLD ADAMS, Assistant, Combustion Dept., Bethlehem Steel Co., Grey Mill Office, Bethlehem; res., So. Bethlehem, Pa.

BAUMGARDNER, CLAUDE GEROLD, Elec. Construction Foreman, Monongahela West Penn. Public Service Co., 504 Bethlehem Bldg., Fairmont, W. Va.

BEART, ERNEST ALFRED, Estimating Distribution Dept., Toronto Hydro-Electric System, Duncan St., Toronto, Ont., Can.

BEAUMONT, WILLIAM M., Telephone Engineer, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.; res., Summit, N. J.

BECKER, THEODORE, Inside Plant Div., Engg. Dept., Commonwealth Edison Co., 72 W. Adams St., Chicago, Ill.

BECKERLEA, HERBERT, Sub-Foreman, Pacific Gas & Electric Co., 245 Market St., San Francisco; for mail, Oakland, Calif.

BENDER, ERHARD, Electrician, Goodyear Tire & Rubber Co., Plant 2, Akron, Ohio.

BENSON, OSCAR E., Telephone Engineer, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.

BENTLEY, ELLSWORTH F., Chief Draftsman, G. & W. Electric Specialty Co., 7789 Dante Ave., Chicago, Ill.

*BERGEVIN, WILLIAM PETER, Instructor, Rensselaer Polytechnic Institute, Troy, N. Y.

BERRY, CLARENCE HERVEY, Telephone Engineer, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.

*BERRY, HENRY PARMENTER, Engineering Assistant, Chesapeake & Potomac Telephone Co., 725 13th St., Washington, D. C.

BEST, EUGENE M., In charge of Electrical Work, De Vilbiss Mfg. Co., 3750 Detroit Ave., Toledo, Ohio.

BEVERS, PLEZ T., Traveling Representative, Electric Railway Improvement Co., Cleveland, Ohio.

BLAY, J. A., Salesman, Canadian Westinghouse Co., Metropolitan Bldg., Toronto, Ont., Can.

*BOCK, JOHN A., Design Engineer, Westinghouse Elec. & Mfg. Co., Sharon, Pa.

BOOLBA, P. M., Engineer, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.

*BOOTH, LOUIS FARRAND, Production Clerk, Century Electric Co., 18th & Pine Sts., St. Louis; res., Webster Groves, Mo.

*BOSTWICK, WILLIAM E., Estimator, Elec. Dept., Wisconsin Public Service Corp., 100 S. Washington St., Green Bay, Wis.

BOSWAU, HANS PAUL, Asst. Chief Engineer, North Electric Mfg. Co., Galion, Ohio.

BOYAU, JEAN, Resident Representative, French Thomson-Houston Co.; International General Electric Co., Schenectady, N. Y.

BRACKMAN, HAROLD, Jr., Asst. Distribution Engineer, Union Electric Light & Power Co., 315 N. 12th Blvd., St. Louis, Mo.

BRANDT, WILLIAM A., Dist. Operating Engineer, Automatic Electric Co., 427 Bourse Bldg., Philadelphia, Pa.

*BRIDGE, LAWRENCE RAYMOND, Instructor, Elec. Engg. Dept., Cornell University, Ithaca, N. Y.

*BRIXNER, FREDERICK W., Electrical Engineer, Engg. Dept., General Railway Signal Co., Rochester, N. Y.

BROOKE, HENRY L., Jr., Sales Manager, Pacific Electric Mfg. Co., 5815 Third St., San Francisco; res., Mill Valley, Calif.

*BROUGHTON, WILLIAM GUNDRY, Student Engineer, General Electric Co., Schenectady, N. Y.

BROWN, JOHN FRANKLIN, Supt., Elec. Dept., City of Longmont, Longmont, Colo.

*BROWN, NELSON E., Chief Draughtsman, Niagara Lockport & Ontario Power Co., 604 Lafayette Bldg., Buffalo, N. Y.

*BROWN, ROY LEO, Design Engineer, Westinghouse Elec. & Mfg. Co., Sharon, Pa.

BROWNE, OSBORNE ARTHUR, Asst. Electrical Engineer, West Lynn Works, General Electric Co., West Lynn; res., Belmont, Mass.

*BROWNLEE, THEODORE, Lighting Arrester Engg. Dept., General Electric Co., Pittsfield, Mass.

*BURKE, CHARLES THOMAS, Electrical Engineer, General Radio Co., 30 State St., Cambridge; res., Watertown, Mass.

*BURROWS, CHARLES RUSSELL, Radio Research Engineer, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.; res., South Orange, N. J.

*BUTTON, CHARLES TITSWORTH, Asst. Engineer, Union Gas & Electric Co., 1107 Plum St., Cincinnati, Ohio.

*BUTZER, J. D., Tester, Westinghouse Elec. & Mfg. Co., Sharon, Pa.

CARMER, B. H., Jr., Instructor, Rensselaer Polytechnic Institute, Troy, N. Y.
*CARVILLE, ELLSWORTH MAGUIRE, Small Motor Engineer, Westinghouse Elec. & Mfg. Co., East Springfield Works, Springfield, Mass.
*CASE, HARLOW MILLS, Engg. Apprentice, Traffic Dept., Western Union Telegraph Co., Cor. Congress & Shelby Sts., Detroit, Mich.
CASS, JOHN CLARENCE, Jr., Mgr., Eastern Service Div., Music Master Corp., 128-130 N. 10th St., Philadelphia, Pa.
CATLIN, F. H., Head of Standardizing Laboratory, General Electric Co., Erie, Pa.
CHAMBERLAIN, HARRY LEE, Jr., Asst. Elec. Repair Foreman, Pennsylvania Power & Light Co., Hauto, Pa.
CHAMBLISS, JOSEPH MAURICE, Testman, Utica Gas & Electric Co., 222 Genesee St., Utica, N. Y.
*CHAMBLISS, LAUREN MORGAN, Asst. Material Engineer, Dixie Construction Co., Alabama Power Co. Bldg., Birmingham, Ala.
*CHANG, WAKEN, Student Engineer, Westinghouse Elec. & Mfg. Co., 417 Center St., Wilkinsburg, Pa.
*CHANN, THOMAS, Radio Engineer, Boston Radio Co., 506 West 122nd St., New York, N. Y.
CHAPMAN, WALLACE, Appliance Salesman, Mississippi Power Co., Biloxi; res., Bay Saint Louis, Miss.
CHAREST, JOHN J., Supt. of Transmission, East Penn Electric Co., Pottsville, Pa.
*CHETHAM-STRODE, ALFRED, Switchboard Engineer, General Electric Co., 1 River Road, Schenectady, N. Y.
CHILOFSKY, JOSEPH, Electrical Construction, Richmond Station, Philadelphia Electric Co., Philadelphia, Pa.
CHOPRA, HUKM CHAND, Electrical Engineer, Supply Dept., Westinghouse Elec. & Mfg. Co., Newark, N. J.
CISIN, HARRY GEORGE, 1400 Broadway, New York, N. Y.
CLARK, WILLIAM BRYAN, Sales Agent, General Electric Co., 508 U. S. National Bank Bldg., Denver, Colo.
CLAYTON, CHARLES JAMES, Engg. Apprentice, Canadian Westinghouse Co., Ltd., Hamilton, Ont., Can.
CLEMENCE, ELLIOT IRVING, Consulting Engineer, 154 Kensington Ave., Jersey City, N. J.; for mail, New York, N. Y.
COBBAN, ROLLO J., Special Representative, Westinghouse Elec. & Mfg. Co., 801 Porter Bldg., Portland, Ore.
*COOPER, JOHN BRADLEY, Test Man, General Electric Co., Schenectacy, N. Y.
CORWIN, JOSEPH W., Equipment Engineer, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.
COWAN, CLIFFORD SAMUEL, Technical Inspector, Brooklyn Edison Co., Inc., 561 Grand Ave., Brooklyn, N. Y.
CRAIG, DONALD K., Sales Engineer, Weston Electrical Instrument Corp., 112 S. 16th St., Philadelphia, Pa.
CRANE, RALPH EMERSON, Telephone Engineer, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.
CRITSKY, MITROPHON, Engineer, Trey Motors Corp.; Neutroliser, Inspector's Dept., Freed-Eiseman Co., 501 W. 21st St., New York, N. Y.
*CRONE, ROBERT HENRY, Material Engineer, Phoenix Utility Co., Hazleton, Pa.
CROSBY, MURRAY GRIMSHAW, Student Engineer, Radio Corp. ofrAmerica, Belfast, Maine.
*CURL, HERBERT C., Engineer, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.
CURLEY, JAMES CLAUD, Electrical Fitter, Newcastle City Council, 48 Lawson St., Hamilton, Aus.
DAUS, GEORGE ADOLPH, Elec. Engg. Dept., The Detroit Edison Co., 2000 Second St., Detroit, Mich.
*DAVENPORT, JUNIUS CLAY, Jr., Engineering Assistant, Chesapeake & Potomac Telephone Co., 725 13th St., N. W., Washington, D. C.
DAVIS, RICHARD CHURCHILL, Telephone Engineer, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.
*DEL DUKE, VENOSTEN JOSEPH, Meter Dept., Utah Copper Co., Magna; res., Salt Lake City, Utah.
DELO, WILLIAM ALBERT, Electrical Engineer, Pennsylvania & Ohio System, Engg. Office, Youngstown, Ohio.
*DENAULT, CLINTON LOUIS, Laboratory Assistant, Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.
DENMEAD, HARRELL, Electrical Engineer, Appalachian Power Co., Bluefield, W. Va.
*DEXTER, HOWARD WALKER, Jr., Electrical Engineer, H. C. Fugate Engineering Co., West Palm Beach, Fla.
*DHAR, MATILAL, Graduate Student, Frick Co., Waynesboro Pa.
*DONALDSON, KENNETH MILLER, Inspection Bureau, Electric Bond & Share Co., 71 Broadway, New York; res., Brooklyn, N. Y.
DONOVAN, WILLIAM ERNEST, Personnel Dept., Consumers Power Co., Jackson, Mich.
*DOTY, WENDELL E., Radio Technician, Brunswick, Balke-Collender Co., 1102 Farnum St., Omaha Nebr.
*DOW, LOWELL JORDAN, Student Engineer, New York Telephone Co., 158 State St., Albany, N. Y.
*DRAPER, THOMAS, Electrical Test Man., Westinghouse Elec. & Mfg. Co., East Pittsburgh; res., Swissvale, Pa.
DRODJIN, ALEXANDER JOHN, Graduate Student, Stanford University, res., Palo Alto, Calif.
DUNLOP, JOHN JOSEPH, Testing Apparatus Inspector, New York Telephone Co., 204 Second St., New York, N. Y.
DURANT, WILLIAM T., Steam-Electric, Operating Engineer, Power House No. 2, City of Regina, Regina, Saskatchewan, Can.
*EARLE, JAMES WILLIAM, Engineer of Construction, General Electric Co., 20 Washington Place, Newark, N. J.
EASLEY, ROBERT MARSHALL, A. C. Designing Dept., General Electric Co., Schenectady, N. Y.
EASTMAN, AUSTIN V. Instructor, College of Engineering, University of Washington, Seattle, Wash.
*ELDRIDGE, TAUSIAS IRVEN, Jr., Laboratory Assistant, Electric Service Supplies Co., 7th & Cambria Sts., Philadelphia; res., Brookline, Del. Co., Pa.
EMANUELS, HUBERT S., Sales Engineer, Fairbanks Morse & Co., 550 1st Ave. S., Seattle, Wash.
*ENGSTRAND, WALDO A., Inspector, Edison Elec. Illuminating Co. of Boston, 1165 Massachusetts Ave., Boston, Mass.
EPLETVEIT, HALVOR H., Elec. Constr. Man, United Electric Light & Power Co., Hell Gate Power Station, New York; res., Brooklyn, N. Y.
EWALD, HARRY W., In charge of Publicity on Automatic and Outdoor Stations, General Electric Co., Schenectady, N. Y.
FALEY, GEORGE J. V., Telephone Engineer, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.
FARKAS, SANFORD, Illuminating Engineer, Holophane Glass Co., 342 Madison Ave., New York, N. Y.
FARMAN, CHARLES D., Electrical Engineer, Murrie & Co., 45 E. 17th St., New York, N. Y.
FARMER, ERIC WESTOVER, Test Engineer, Can. Marconi Co., 173 William St., Montreal, Que., Can.
*FARRAR, WALTER BATTEAL, Graduate Student, Westinghouse Elec. & Mfg. Co., East Pittsburgh; res., Wilkinsburg, Pa.
*FEASTER, WILBUR CULLER, Elec. Construction Dept., The Potomac Edison Co., Hagerstown; res., Baltimore, Md.
FENLON, DERMOT RALPH JOHN, 73 W. 102nd St., New York, N. Y.
*FEARN, ELLSWORTH ELMER, Radio Engineer, Westinghouse Elec. & Mfg. Co., East Pittsburgh; res., Wilkinsburg, Pa.
*FISCHER, HERBERT B., Engineer, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.
FISHER, GEORGE HENRY BEATTY, Canadian & General Finance Co., Ltd., 357 Bay St., Toronto, Ont., Can.
FITHIAN, LESLIE S., President & Electrical Engineer, West Jersey Electrical & Construction Co., 905 Division St., Camden, N. J.
*FITZGERALD, JOSEPH WILFRID, Timekeeper & Engineer, The Van Blarcom Construction Co., 606 National City Bldg. Cleveland, Ohio.
FORD, R. B., Memphis Power & Light Co., Memphis, Tenn.
FRANCE, WALTER HAMILTON, Division Plant Engineer, Michigan Bell Telephone Co., 131 S. Franklin Ave., Saginaw, Mich.
FREEMAN, MAURICE TILSON, Teacher of Electrical Construction, East Technical High School, Cleveland, Ohio.
*FRESHWATERS, EDISON CREAL, Oil Engineer, Fairbanks-Morse Co., South Haven, Mich.
FULLER, JOHN BRADLEY, Meter Repair Man, Philadelphia Electric Co., 2301 Market St., Philadelphia, Pa.; res., Pitman, N. J.
*FURBER, JOHN ROSCOE, Sales Engineer, Northern States Power Co., 15 S. 5th St., Minneapolis, Minn.
GALLAGHER, JOHN DONALD, Ass't. Electrical Engineer, Underwriters' Laboratories, 207 E. Ohio St., Chicago, Ill.
GARIN, ALEXIS NICHOLAS, Transformer Engg. Dept., General Electric Co., Pittsfield, Mass.
GAUBERT, JOHN QUINN, Instructor, Electrical Trade Drawing, New York City Board of Education, Vocational School for Boys, 138th St. & 5th Ave., New York; res., Yonkers, N. Y.
GIALIAS, GEORGE E., Engineering Assistant, New York Edison Co., 5 S. Oxford St., Brooklyn, N. Y.
*GIERING, PERCIVAL L., Chief Electrician, Hudson Valley Coke & Products Corp., Troy, N. Y.
*GLENN, KARL BROWNING, Manager, Central Florida Power & Light Co., Brooksville, Fla.
GOODWIN, ALAN MAURICE, Engineer, General Electric Co., 84 State St., Boston, Mass.
*GOODWIN, ROBERT CARROLL, Regular Tester, Westinghouse Elec. & Mfg. Co., Wilkinsburg, Pa.
*GRANTHAM, FREDERICK WILLIAM, Jr., Commercial Engineer, Brooklyn Edison Co., 380 Pearl St., Brooklyn, N. Y.
GREEN, ALBERT, 1st Class Electrical Mechanic, Brooklyn Edison Co., Inc., Hudson Ave. Sta., Brooklyn, N. Y.
*GREENE, F. MELVILLE, Sales Engineer, Westinghouse Elec. & Mfg. Co., 150 Broadway, New York; res., Brooklyn, N. Y.
*HAMBURGER, FERDINAND, Jr., N. E. L. A. Research Assistant, Johns Hopkins University, M. & E. Bldg., Homewood, Baltimore, Md.
HANNA, WILLIAM McAFEE, Test Dept., General Electric Co., 1 River Rd., Schenectady, N. Y.

HANSEN, BENJAMIN HARRISON, Electrical Designer, Constr. Dept., H. L. Doherty & Co. 60 Wall St., New York, N. Y.
HANSEN, EARL B., Engineer, The Pacific Tel. & Tel. Co., 140 New Montgomery St., San Francisco, Calif.
*HARDY, HELEN WILLIAMS, Asst. to General Lighting Representative, Public Service Electric & Gas Co., 80 Park Place, Newark, N. J.
HARPER, ROBERT W., Telephone Engineer, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.
HEATH, CORNELIUS ELLIOTT, Sales Dept., General Electric Co., 123 Spring St., Atlanta; res., Augusta Ga.
*HENDERSON, FRANCIS LOUIS, Switchboard Requisition Engineer, General Electric Co., 6801 Elmwood Ave., West Philadelphia; res., Philadelphia, Pa.
*HESSELMEYER, CLARENCE THEODORE, Testing Course, General Electric Co., Schenectady, N. Y.
*HILL, BYRON R., Meter Specialist, Westinghouse Elec. & Mfg. Co., 111 W. Washington St., Chicago, Ill.
HINKLE, AMBROSE H., Chief Electrician, Chas. M. Dodson Coal Co., Beaver Brook, Pa.
HOARD, JAMES L., Electrical Instructor, Ralston Industrial School, 15th & Penn. Ave., Pittsburgh, Pa.
*HOEDEMAKER, PETER, Journeyman Electrician, 1066 McBride Ave., Little Falls, N. J.
*HOLLADAY, WILLIAM LEE, Refrigerator Specialist, General Electric Co., Schenectady, N. Y.
HOLROYD, HOWARD B., Engineer, Power Engg. Dept., Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.
HOOD, KUPER Jr., Columbia Power Co., 1107 Plum St., Cincinnati, Ohio.
*HOTCHKISS, THOMAS MYRON, Student Engineer, General Electric Co., River Works, Lynn, Mass.
*HOWITT, NATHAN, Instructor, Elec. Engg. Dept. The Harvard Engineering School, Pierce Hall, Cambridge, Mass.
HUGGETT, WILLIAM HENRY, Electrical Engineer, Borough of New Plymouth, New Plymouth, N. Z.
*HUGHES, LESTER LEONARD, Commercial Engineer, International General Electric Co., Schenectady, N. Y.
HUNTLEY, HARRY LEWIS, Electrical Engineer, Wilkes-Barre Lace Mfg. Co., Courtright & Darling Sts., Wilkes-Barre; res., Pittston, Pa.
HYATT, CLINTON BROWN, Radio Engineer, 1701 Arch St., Philadelphia, Pa.
IDE, CLINTON, Salesman, Allis-Chalmers Mfg. Co., 917 Coal Exchange Bldg., Wilkes-Barre, Pa.
IRWIN, BRYAN, Inspector, Transmission & Distribution Dept., United Electric Light & Power Co., E. 15th St., New York, N. Y.
*JACKSON, GEORGE J., Inspector, Brooklyn Edison Co., 360 Pearl St., Brooklyn; res., West New Brighton, N. Y.
*JACKSON, JOHN EARLY, Electrical Engineer, Lynchburg Traction & Light Co., Lynchburg, Va.
JACOBS, ALBERT HENNING, Electrical Draftsman, Engg. Dept., Alabama Power Co., Birmingham, Ala.
JACOBY, ARTHUR CLARK, Asst. Local Test Engineer, Pennsylvania Power & Light Co., Allentown, Pa.
JENKS, LOREN MORGAN, Salesman, Westinghouse Elec. & Mfg. Co., 425 E. Water St., Milwaukee, Wis.
JENSTEAD, SEVER EDWARD, Construction Foreman, North Pacific Public Service Co., 309 Fourth St., Bremerton, Wash.
JOHNSON, GROVER, Inside Plant Div., Engg. Dept., Commonwealth Edison Co., 72 W. Adams St., Chicago, Ill.
JOHNSON, MARION STEWARD, Engineer, Cumberland Tel. & Tel. Co., Jackson, Miss.
JOHNSON, RICHARD C., Telephone Equipment Engineer, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.
*JOHNSON, WALTER CHARLES, Facility Engineer, Ohio Bell Telephone Co., 523 W. Main St., Springfield, Ohio.
JOHNSON, WILLIAM THEODORE, Electrician, Blau's Electric Shop, Main St., Middletown, Conn.
JOHNSTON, OSWALD DANIEL, Sales Engineer, D. M. Fraser, Ltd., 24 Adelaide St., East, Toronto, Ont., Can.
JOLY, PAUL FRANCIS, Asst. Station Tester, Brooklyn Edison Co., 14 Rockwell Place, Brooklyn; res., New York, N. Y.
JONES, LESTER S., Research Engineer, Socony Burner Corp., 41st & 2nd Ave., Bush Terminal Bldg., Brooklyn, N. Y.
JORE, BJORN, Tester, Brooklyn-Manhattan Transit Corp., 500 Kent Ave., Brooklyn, N. Y.
KAYSER, CHARLES FREDERICK, General Foreman, Commonwealth Edison Co., 72 W. Adams St., Chicago, Ill.
*KELLER, CHARLES W., Salesman, Central Station Dept., General Electric Co. 508 U. S. National Bank Bldg., Denver, Colo.
KELLY, MAURICE JAMES, Elec. Engineer, Asst. Supt. of Operation, Electric Service Corp., Shawinigan Falls, P. Q., Can.
KENNEALLY, DANIEL JAMES, Cable Tester, The New York Edison Co., 708 1st Ave., New York, N. Y.
*KENT, PAUL NICHOLAS, Draftsman, City Engineer's Office, City Hall, Kansas City, Mo.
KEPPICUS, HERBERT, Telephone Engineer, Bell Telephone Laboratories, Inc., 463 West St., New York; res., Queens Village, N. Y.
KING, DONALD COOPER, Asst. Editor, *Electrical World*, McGraw-Hill Co., 10th Ave. & 36th St., New York, N. Y.
*KINGDON, HOWARD F., Transformer Engineer, Canadian Crocker-Wheeler Co., St. Catharines, Ont., Can.
*KNOPP, OTTO REINHOLD HERMAN, Technical Assistant, Patent Dept., Submarine Signal Corp., 160 State St., Boston 9; res., West Somerville, Mass.
*KOCH, CHARLES J., Designing Engineer, Induction Motor Dept., General Electric Co., Schenectady, N. Y.
KONN, FELIX, Student Engineer, General Electric Co., Schenectady, N. Y.
KONSTANTINOWSKY, KURT, Technical Expert, Cable Manufacturing Co., Ltd., Bratislava, Czechoslovakia.
KRAMER, WILLIAM BRENT, Fieldman, Duquesne Light Co., Duquesne Bldg., Pittsburgh, Pa.
KREIDER, ROY H., Telephone Engineer, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.
*KRIEGSHAUSSER, JOHN, Elec. Shop Teacher, John S. Hart Continuation School, Philadelphia, Pa.
KRON, JOSEPH, Trade Work, 69 W. 52nd St., New York, N. Y.
*KRUEGER, DAVID E., Engineer, Western Union Telegraph Co., 230 S. 11th St., Philadelphia, Pa.
KUBALE JOHN CHARLES, Student Engineer, General Electric Co., Schenectady, N. Y.
KURTZ, HENRY J., Elec. Engg. Dept., Commonwealth Power Corp., Jackson, Mich.
KUTTICH, JOHN, Electrical Engineer, 463 Manhattan Ave., New York, N. Y.
*LAMBORN, RICHARD, Student Engineer, General Electric Co., Erie, Pa.
*LANDER, HAROLD M., Engineer, New England Tel. & Tel. Co., 50 Oliver St., Boston; res., Dorchester, Mass.

*MAHLEY, FRED W., Tester, Westinghouse Elec. & Mfg. Co., E. Pittsburgh; res., Wilkinsburg, Pa.
MANIGAULT, EDWARD LINING, Sales Engineer, General Electric Co., Fairmont, W. Va.
MARETZO, CHARLES B., Junior Engineer, Test Dept., Brooklyn Edison Co., 380 Pearl St., Brooklyn, N. Y.
MASON, HOWARD F., Elec. Engg. Dept., Llewellyn Iron Works, 1200 N. Main, Los Angeles; res., Eagle Rock, Calif.
*MASON, RURIC COIN, Engineer, Materials & Process Engg. Dept., Westinghouse Elec. & Co., East Pittsburgh; res., Wilkinsburg, Pa.
MAYS, PAUL EDGAR, Meter Tester, Virginia-Western Power Co., Clifton Forge, Va; res., Lewisburg, W. Va.
McCLAIN, WALTER J., Electrical Construction Designer, Philadelphia Electric Co., 1035 Chestnut St., Philadelphia, Pa.
McCLUSKEY, FRANCIS J., Division Supt., Utah Power & Light Co., Park City, Utah.
*McCULLOUGH, MAURICE BARNARD, Engineer, General Electric Co., Schenectady, N. Y.

McCURDY, BRUCE HUDSON, Engineering Assistant, New England Tel. & Tel. Co., 50 Oliver St., Boston, Mass.
*McELHENY, GEORGE BUSHFIELD, Technical Clerk in Office of V. P. & G. M., Duquesne Light Co., 435 6th Ave., Pittsburgh, Pa.
*McMURRAN, MARSHALL J., Station Operator, Grace Power Plant, Utah Power & Light Co., Grace, Idaho.
*MEAKER, OSCAR PHELPS, Illuminating Engineer, National Lamp Works, General Electric Co., Nela Park, Cleveland, Ohio.
*MEARS, GILBERT ELTON, Equipment Inspector, Michigan Bell Telephone Co., 1365 Cass Ave., Detroit, Mich.
MERIGAN, EDMUND LESLIE, Test Man, General Electric Co., Schenectady, N. Y.
MERRILL, LELAND HAWTHORNE, Resident Engineer, Elec. Construction, Chas. H. Tenney & Co., 200 Devonshire St., Boston; res., Melrose, Mass.
MEYER, FRANK THEODORE, Telephone Equipment Engineer, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.
MILLER, RALPH J., Telephone Systems Engineer, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.
MILLIGAN, ROBERT J., Asst. Engineer, Sta. Elec. Design & Construction Dept., The Philadelphia Electric Co., 1000 Chestnut St., Philadelphia, Pa.
*MILLS, NEIL, Engg. Apprentice, Century Electric Co., 1827 Pine St., St. Louis, Mo.
*MONSETH, INGWALD T., Switchboard Engineer, Switchboard Eng. Dept., Westinghouse Elec. & Mfg. Co., East Pittsburgh; res., Wilkinsburg, Pa.
*MOORE, CARLTON H., Technical Assistant, U. G. Div., Duquesne Light Co., Pittsburgh, Pa.
*MOORE, LAURISTON GREENE, Jr., Manager, Florida Electric Supply Co., 120 N. E. 20th St., Miami, Fla.
MOSCHEL, WILLIAM K., Underground Engineering, Commonwealth Edison Co., 72 W. Adams St., Chicago, Ill.
*MUCKENHAUPT, CARL FREDERICK, Transmission Engineer, Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.
MUELLER, REINHOLD, Draftsman & Designer, G. & W. Electric Specialty Co., 7780 Dante Ave., Chicago, Ill.
*MUELLER, WALTER E., Instructor, Elec. Engg., Syracuse University, Syracuse, N. Y.
*MURPHY, ELOY JOHN, Maintenance Engineer, New York Telephone Co., 309 Washington St., Newark, N. J.
MURPHY, FORD ANDREW, Sales Engineer, Alfred Collyer & Co., 183 George St., Toronto, Ont., Can.
MYERS, DAYL S., Telephone Equipment Engineer, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.
NELSON, WILLIAM ARTHUR, Member, Technical Staff, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.
*NIVEN, CHARLES KEARNEY, Mechanic, Atlantic Basin Iron Works, Van Brunt & Imlay Sts., Brooklyn, N. Y.
NOBLE, WILLIAM DAVID, Laboratory Assistant, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.
*NOVY, ALOIS JARDSLAV, Asst. to Mr. Fayer, Wappler Electric Co., Inc., 162-194 Harris & Val Alst Ave., Long Island City; res., Great Neck, N. Y.
NUMATA, SHICHIJIRO, Telephone Engineer, The Imperial Government Communication Ministry in Japan, Nakanomachi near Tokyo, Japan.
OFFERDAHL, EINAR, Engg. Draftsman, New York Central Railroad Co., 466 Lexington Ave., New York; res., Brooklyn, N. Y.
*OLIVER, RODOLPH STEWART, Jr., Salesman, Florida Electric Supply Co., Miami, Fla.
OLSON, MARVIN S., Electrical Engineering, Carver Radio & Electric Laboratory, Carver, Minn.
OWEN, FREDERICK CARLISLE, Inventor & Manufacturer of Electric Welding Apparatus, Fayetteville, N. C.
*PALMER, GLENN HUNTER, Commissioned Officer, Signal Corps, U. S. A., c/o Adjutant General, U. S. A., Washington, D. C.; for mail, c/o California Inst. of Technology, Pasadena, Calif.
PARKER, JOHN, Jr., Draftsman, Philadelphia Electric Co., Philadelphia, Pa.
*PARKER, RAY H., Engineer, Pacific Tel. & Tel. Co., 140 New Montgomery St., San Francisco, Calif.
PAUL, HARRY J., Sales Engineer, Century Electric Company, Saint Louis, Mo.
PAUL, THEODORE, Telephone Engineer, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.
PENNEY, GAYLORD WALLIS, Engineer, Power Dept., Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.
PENNEY, WILLIAM MARCHANT, Jr., Ass't. Distribution Engineer, Union Electric Lt. & Pr. Co., 315 N. 12th St., St. Louis, Mo.
*PHILLIPS, STANLEY NEVILLE, Engineering Apprentice, Century Electric Co., 1806 Pine St., St. Louis, Mo.
PILKINGTON, JOHN HENRY, Technical Assistant, Brooklyn Edison Co., Pearl & Willoughby Sts., Brooklyn, N. Y.
*PREISMAN, ALBERT, Elec. Engg. Assistant, The New York Edison Co., 140th St. & Rider Ave., New York, N. Y.
RAE, O. O., Sales Engineer, Westinghouse Elec. & Mfg. Co., 426 Marietta St., Atlanta, Ga.
*RANSON, RICHARD R., Electrical Engineer, Experimental Dept., Cutler-Hammer Mfg. Co., Milwaukee, Wis.
RAPP, CARL P., Transmission Engineer, Bell Telephone Co. of Pennsylvania, 1230 Arch St., Philadelphia, Pa.
REARDON, MICHAEL F., Technical Clerk, Mountain States Tel. & Tel. Co., 800 14th St., Denver, Colo.
*REED, CALVIN FRANCIS, Student, International Standard Electric Corp., 25 Broad St., New York; res., Brooklyn, N. Y.
REED, F. FOSTER, Laboratory Assistant, Public Service Elec. & Gas Co., 21st St. & Clinton Ave., Irvington; res., Jersey City, N. J.
REED, GEORGE VICTOR, Chief Engineer, Provincial Hospital, Province of Saskatchewan, for mail, Weyburn, Sask., Can.
*REED, HARRY R., Jr., Special Apprentice, Norfolk & Western Railway Co., Roanoke, Va.
REED, WILLIAM H., Electrical Engineer, Tietjen & Lang Dry Dock Co., 17th St. & Park Ave., Hoboken, N. J; res., South Norwalk, Conn.
RICHARD, ERNEST CAMP, Asst. to Transmission Engineer, Florida Power & Light Co., Miami Beach, Fla.
RICHARDSON, MARSTON SAMUEL, Facilities Engineer, Wisconsin Telephone Co., 418 Broadway, Milwaukee, Wis.
RICHARDSON, RICHARD PAUL, Asst. Engineer, Electricity Dept., Sydney Municipal Council, Sydney, Austrailia.
RIHANEK, LADISLAV V., Electrical Designer, T. E. Murray, Inc., 55 Duane St., New York; res., Brooklyn, N. Y.
RIPLEY, NELSON ALDEN, Head of Material Dept., Phoenix Utility Co., Cienfuegos, Cuba.
ROBERTS, GEORGE ARTHUR, Telephone Equipment Engineer, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.
*ROBERTSON, GEORGE BAKER MAHN, Supervisor of Testing, Meter Laboratory, Philadelphia Electric Co., 2301 Market St., Philadelphia, Pa.
ROBSON, JOHN GREENFIELD, Operator, British Columbia Electric Railway Co., Vancouver, B. C.
ROESER, JOSEPH PETER, Inspector, Brooklyn Edison Co., Inc., Pearl & Willoughby Sts., Brooklyn, N. Y.
ROHDE, CHARLES F., Appraisal Engineer, Murrie & Co., 45 E. 17th St., New York; res., Brooklyn, N. Y.
ROLLOW, JAMES GRADY, Electrical Engineer, Los Angeles Gas & Electric Corp., 810 South Flower St., Los Angeles, Calif.
ROLNICK, Harry, Electrician, International Motor Co., 216 Seaman St., New Brunswick, N. J.
*ROSENBURG, EVERETT REYNOLDS, Student, Cornell University, 306 Stewart Ave., Ithaca, N. Y.
ROSS, DONALD, Member, Technical Staff, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.
*ROTH, JESSE E., Multiplex Plant Attendant, Western Union Telegraph Co., 7th & Walnut Sts., Kansas City, Mo.
*ROWLAND, DAVIDGE HARRISON, Engineer, Locke Insulator Corp., S. Charles & Cromwell Sts., Baltimore, Md.
*RUMSEY, PAUL TRUMAN, Instructor, Dynamo Laboratory Dept., Mass. Institute of Technology, Cambridge, Mass.
*SAMS, JAMES HAGOOD, Jr., Student, Cornell University, 324 College Ave., Ithaca, N. Y.
SAPPER, ROBERT T., Asst. Purchasing Agent, Century Electric Co., 1806 Pine St., St. Louis, Mo.
*SCHACHT, DELBERT HERMANN, Sales Engineer, Century Electric Co., 628 Granite Bldg., Rochester, N. Y.
SCHARDT, FREDERICK O., Foreman, Electrical Construction, Public Service Production Co., Kearny; res., Edgewater, N. J.
*SCHLECHTER, ARTHUR HERMAN, Estimator, New York & Queens Electric Light & Power Co., Central Service Sta., Flushing; for mail, Corona, N. Y.
*SCHMIDT, EUGENE, Tester, New York & Queens Electric Light & Power Co., Flushing; res., Brooklyn, N. Y.
SCHMITTER, RAY M., Inspection Maintenance Engineer, Western Electric Co., Inc., Hawthorne Sta., Chicago, Ill.; for mail, Mercedes, Texas.
*SCHROEDER, JOHN HENRY, Specification Engineer, Commonwealth Edison Co., 635 Edison Bldg., Chicago, Ill.
*SHEA, DENNIS C., Asst. to Electrical Engineer, Standard Oil Co., Bayway Refinery, Elizabeth, N. J.
SHELLEY, HARRY SANDBERG, Engr., Distribution Dept., Consolidated Gas & Electric Co., Monument & Constitution Sts., Baltimore, Md.
SIMON, RAPHAEL B., Telephone Systems Engineer, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.
*SIPKIN, GEORGE, Estimator, Interborough Rapid Transit Co., 600 W. 59th St., New York; res., Brooklyn, N. Y.
SISKIND, CHARLES S., Instructor, Milwaukee Vocational School, 6th & Prairie Sts., Milwaukee, Wis.
SKENE, ANDREW ALLISON, Engineer, Union Switch & Signal Co., Swissvale, Pa.
SKINNER, WILLIAM A., Electrical Foreman, Pennsylvania Power & Light Co., 117 E. Broad St., Hazleton, Pa.
SMITH, ARTHUR WILLIAM, Valuation Engineer, Murrie & Co., 45 E. 17th St., New York, N. Y.; res., Jersey City, N. J.
SMITH, ERMY R., Telephone Engineer, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.; res., Maplewood, N. J.
SMITH, HOWARD MARSHALL, Vice-President, S. Edw. Eaton & Co., 591 Hudson St., New York, N. Y.

*SONNEMANN, WILLIAM KNOX, Electrical Engineer, Westinghouse Elec. & Mfg. Co., East Pittsburgh; res., Wilkinsburg, Pa.

SONNENFELD, HUGO, Chief Engineer & General Superintendent, Cable Manufacturing Co., Ltd., Bratislava, Czechoslovakia.

*STANKA, ERHARDT W., Electrical Designer, H. L. Doherty & Co., 60 Wall St., New York, N. Y.; res., Belleville, N. J.

STANLEY, JACK SQUIRE, Line Foreman, Los Angeles Railway Corp., 717 E. 16th St., Los Angeles, Calif.

STERNBERG, THEODORE AUGUST, Electrical Draftsman, New York Rapid Transit Co., 85 Clinton St., Brooklyn, N. Y.; res., North Bergen, N. J.

STROESSLER, HANS M., Draftsman, Commonwealth Edison Co., 72 W. Adams St., Chicago, Ill.

*STRONG, EVERETT MILTON, Instructor, Elec. Engg. Dept., Cornell University, Ithaca, N. Y.

STUMPF, MALCOLM WENDLING, Student Engineer, New Orleans Public Service, Inc., 201 Baronne St., New Orleans, La.

SUMMERS, CLIFFORD JOHN, Armature Winder, U. S. S. New Mexico, c/o Postmaster, San Francisco, Calif.

SUMMERS, HARRY ANDERSON, Engg. Dept., Bell Telephone Laboratories, Inc., 463 West St., New York; res., Brooklyn, N. Y.

SUTHERLAND, GEORGE ELMER, Electrician, Gibbs & Hill, Mullins; for mail, Princeton, W. Va.

SWORDS, EVERETT LAVON, Foreman of Operation, California-Portland Cement Co., Colton; res., San Bernardino, Calif.

*TANCK, HENRY, Asst. Engineer, Motor Engg. Dept., General Electric Co., River Works, West Lynn; res., Boston, Mass.

TAYLOR, ALFRED LINDSAY, Engineering Assistant, New York Telephone Co., 158 State St., Albany, N. Y.

TAYLOR, JAMES REUBEN, Salesman, Westinghouse Elec. & Mfg. Co., 1224 Miners Bank Bldg., Wilkes-Barre, Pa.

*TAYLOR, WILLIAM PRESTON, Electrical Testman, Cons. Gas Electric Lt. & Pr. Co., Baltimore, Md.

*TEALL, HARLEY ALBERT, Student, Kansas State Agricultural College, Manhattan, Kansas.

THERRIEN, RUSSELL WILLIAM, Elec. Engg. Dept., Commonwealth Power Corp., Jackson, Mich.

*THIELEMANN, GEORGE J., Station Electrician, Public Service Co. of No. Illinois, Blue Island, Ill.

*THOMSON, JOHN MILTON, Transformer Engg. Dept., Canadian Crocker-Wheeler Co., Katharine St., St. Catharines, Ont., Can.

TOWNSEND, RICHARD LEE, Engineer's Assistant, Chesapeake & Potomac Telephone Co., 725 13th St., N. W., Washington, D. C.

*TRAVERS, FRED HARTT, Student Engineer, New England Tel. & Tel. Co., 50 Oliver St., Boston; res., Everett, Mass.

TREPTOW, FREDERICK WILLIAM, Telephone Engineer, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.; res., Weehawken, N. J.

UPHAM, EDGAR HARVEY, Supt., French Cable Co., Orleans, Mass.

VAN DENBURG, EARL D., Engineer, The Montana Power Co., Great Falls, Mont.

VASSALLO, ANTHONY, Electrical Expert, Service Shop, General Electric Co., 627 Greenwich St., New York; res., Brooklyn, N. Y.

VROOM, EDWARD, Telephone Engineer, Bell Telephone Laboratories, Inc., 463 West St., New York; res., Ossining, N. Y.

*WAITS, CHARLES EDWARD, Student Engineer, Utica Gas & Electric Co., 222 Genesee St., Utica, N. Y.

*WALL, CHARLES LAYTON, Jr., Student Engineer, General Electric Co., West Lynn; res., Lynn, Mass.

WALTER, GEORGE D., Electrician, Biglerville, Pa.

WATSON, DONALD R., Designer, Philadelphia Electric Co., 1000 Chestnut St., Philadelphia, Pa.

WEAVER, EARLE F., Division Supt., Pennsylvania Power & Light Co., Mt. Carmel, Pa.

WERNER, HAROLD DOUGLAS, Engineer, Foundry Dept., General Electric Co., Erie, Pa.

WETHERELL, DONALD HENRY, Member, Technical Staff, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.

WILLIAMS, HARRY KASTE, General Foreman, General Underground Construction, Hartford Electric Light Co., 266 Pearl St., Hartford, Conn.

WILLIAMS, THOMAS, Dist. Manager, East Penn Electric Co., Minersville, Pa.

WILSON, MYRON SHEDWOOD, Asst. Engineer, Standardizing Laboratory, General Electric Co., West Lynn, Mass.

WINSLOW, JOHN CLIFFORD, Electrical Engineer, Westinghouse Elec. & Mfg. Co., East Springfield, Mass.

WITBECK, ALLEN LEE, Special Apprentice, Chicago, Milwaukee & St. Paul Railway Co., Chicago, Ill.; for mail, Pullman, Wash.

WOLF, HERMAN B., Maintenance Foreman, Southern Power Co., Salisbury, N. C.

WOLFE, T. M., Salesman, Westinghouse Elec. & Mfg. Co., 1224 Miners Bank Bldg., Wilkes-Barre, Pa.

*WOODS, STEPHEN RICHARD, Student Employ, Westinghouse Elec. & Mfg. Co., Murfreesboro, Tenn.

WRIGHT, ROLAND M., Act. General Foreman of Equipment, Cincinnati Street Railway Co., Cincinnati, Ohio.

WYNKOOP, FRANCIS BRUYN, Charge of Elec. Lab. & Meter Dept., Interborough Rapid Transit Co., 600 W. 59th St., New York, N. Y.

Total 352.

*Formerly enrolled Students

ASSOCIATES REELECTED JANUARY 15, 1926

DRAKE, WILLIAM A., Member, Technical Staff, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.

JOHO, E. C., Telephone Equipment Engineer, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.

MacDONALD, DANIEL F., 171 E. 94th St., New York, N. Y.

SWAN, WALTER DOUGLAS, Asst. Foreman, Elec. Laboratory, Interborough Rapid Transit Co., 600 W. 59th St., New York, N. Y.

THOMPSON, STEPHEN WILKINS, Vocational Instructor, Dayton Co-operative Industrial High School, Stivers High School Bldg., Dayton, Ohio.

ASSOCIATES REINSTATED JANUARY 15, 1926

GREGSON, MONTRUVILA EDW., Asst. Superintendent, Bronx District, New York Edison Co., 140th St. & Rider Ave., New York, N. Y.

MEMBERS ELECTED JANUARY 15, 1926

BARKER, JOSEPH WARREN, Assoc. Professor of Elec. Engg., Mass. Institute of Technology, Cambridge, Mass.

BOMAN, CARL EMANUEL, Supervising Equipment Design Engineer, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.

CLARKSON, ALBERT J., General Inspector, Elec. Div., New York Central Railroad Co., Grand Central Terminal, New York, N. Y.

COTA, ALEJANDRO R., Assoc. Editor, Business Publishers International Corp., 1403 Pennsylvania Bldg., New York; res., Queens Village, N. Y.

DIAZ, ENRIQUE, Controller Engineer, The British Thomson-Houston Co., Ltd., Rugby, Eng.

DODGE, WILLIAM LAMB, Engineer, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.

FILER, WILLIAM L., Telephone Engineer, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.

HORR, RAY LECKLEY, Supervisor of Methods & Results, Mountain States Tel. & Tel. Co., 800 14th St., Denver, Colo.

IRISH, JOSEPH, Member of Technical Staff, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.

KELLY, MERVIN, Research Engineer, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.

*KELTON, EDWIN COIT, Major, Corps of Engineers, U. S. Army, Washington, D. C.; res., Bethesda, Md.

KEMP, CHARLES GEORGE RIDGELY, Electrical Engineer, 16 S. 5th St., Reading; res., Wyomissing, Pa.

LATHROP, GEORGE MARTIN, Telephone Engineer, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.; res., East Orange, N. J.

MATTHIES, WILLIAM H., Telephone Engineer, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.

MORTIMER, LOUIS ANDREW, Telephone Engineer, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.

MURPHY, PAUL BUCKNER, Telephone Engineer, Bell Telephone Laboratories, Inc., 463 West St., New York; res., Nyack, N. Y.

OBERNDORF, EDWIN S., Asst. Electrical Engineer, The J. G. White Engineering Corp., 43 Exchange Place, New York, N. Y.

NOBLE, ROY EDWIN, Member, Technical Staff, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.

SHOPE, HARRY STEPHENSON, Telephone Engineer, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.

SMITH, GORDON K., Equipment Development Engineer, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.

TURNER, CLARENCE PORTER, Administrative Assistant, Marine Engg. Dept., General Electric Co., 1 River Road, Schenectady, N. Y.

VOORHIES, MICHEL B., Asst. Professor, Elec. Engg. Dept., Louisiana State University, Baton Rouge, La.

WISHART, RONALD S., Printer & Automatics Engineer, Postal Telegraph-Cable Co., 253 Broadway, New York; res., Rockville Center, N. Y.

FELLOW ELECTED JANUARY 15, 1926

CHATELAIN, MICHAEL A., Professor, Polytechnic Institute of Leningrad; Vice-President Central Electrotechnical Council, Prosp. of 25 October 6, Apt. 7, Leningrad, Russia.

TRANSFERRED TO GRADE OF FELLOW JANUARY 15, 1926

COPLEY, ALMON W., Manager, Engineering Division, Westinghouse Electric & Mfg. Co., San Francisco, Calif.

HIBBARD TRUMAN, Secretary and Chief Engineer, Electric Machinery Mfg. Co., Minneapolis, Minn.

LEEDS, MORRIS E., President, Leeds & Northrup Co., Philadelphia, Pa.

WENNER, FRANK, Physicist, Bureau of Standards, Washington, D. C.

TRANSFERRED TO GRADE OF MEMBER JANUARY 15, 1926

EUSTIS, TRUMAN W., Superintendent, Canadian National Carbon Co., Ltd., Toronto, Ont.

FREEMAN, HADLEY F., Patent Lawyer, Cleveland, Ohio.

GILT, CARL M., Assistant Inside Plant Engineer, Brooklyn Edison Co., Brooklyn, N. Y.

GREEN, CHARLES W., Telephone Engineer, Bell Telephone Laboratories, Inc., New York, N. Y.

HOFFMAN, WILLIAM L., Assistant Engineer, Puget Sound Power & Light Co., Seattle, Wash.

JENNINGS, PHILIP D., Assistant Engineer, Puget Sound Power & Light Co., Seattle, Wash.

LAMB, FRANK B., Consulting Engineer, Member of Firm, West Virginia Engineering Co., Charleston, W. Va.

LOCKWOOD, ALVAH M., Field Superintendent, Phoenix Utility Co. of Cuba, Cienfuegos, Cuba.

LOWENBERG, MAURICE J., Electrical Engineer, Stone & Webster, Inc., Boston, Mass.

LOWRY, HITER H., Telephone Engineer, Bell Telephone Laboratories, Inc., New York.

MACIAS, CARLOS, Chief Engineer, Electromotor, S. A., Mexico D. F., Mexico.

MUSSER, HARRY P. President, West Virginia Engineering Co., Charleston, W. Va.

NETTLETON, LEROY A., Engineering Assistant, Brooklyn Edison Co., Brooklyn, N. Y.

REINMANN, F. L., Supt. Electric Department, Northern Indiana Gas & Electric Co., Hammond, Ind.

RHOADES, WALTER K., Professor of Electrical Engineering, Bucknell University, Lewisburg, Pa.

SHEDD, HORACE E., Superintendent, Appalachian Power Co., Bluefield, W. Va.

STAHL, CHARLES J., Manager, Illuminating Engineering Bureau, Westinghouse Elec. & Mfg. Co., South Bend, Ind.

VALK, EUGENE E., Engineer, Los Angeles Office, General Electric Co., Los Angeles, Calif.

WALKER, EWART B., Electrical Engineer, Canadian National Railways, Toronto, Ont.

WHITE, EDWARD J., Secretary, Treasurer, Engineer, Harris Wright Co., Inc., Newark, N. J.

WILLIAMS, LEROY C., District Manager, Pacific Electric Mfg. Co., Los Angeles, Calif.

RECOMMENDED FOR TRANSFER

The Board of Examiners, at its meetings held January 11 and 25, 1926, recommended the following members for transfer to the grade of membership indicated. Any objection to these transfers should be filed at once with the National Secretary.

To Grade of Fellow

DIXON, AMOS F., Systems Development Engineer, Bell Telephone Laboratories, New York, N. Y.

McIVER, GEORGE W., JR., Asst. Manager, Electrical Dept., Toledo Edison Co., Toledo, Ohio.

THOMS, ALEXANDER P., Asst. Supt., Street Department, Commonwealth Edison Co., Chicago, Ill.

WILLIAMS, SAMUEL B., Telephone Engineer, Bell Telephone Laboratories, New York, N. Y.

To Grade of Member

ADKERSON, BRANCH O., Inside Plant Engineer, American Tel. & Tel. Co., New York, N. Y.

AMBUHL, FRANK F., Asst. Chief Engineer, Toronto Hydro-Electric System, Toronto, Ont.

ARCEO, ANTONIO, Supt. of Distribution, Mexican Light & Power Co., Ltd., Mexico City, Mex.

BELL, JOHN H., Telegraph Engineer, Bell Telephone Laboratories, New York, N. Y.

BOSTATER, HERBERT L., Telephone Engineer, Bell Telephone Laboratories, New York, N. Y.

DAVIS, URIAH, Load Dispatcher, Commonwealth Edison Co., Chicago, Ill.

EASTHAM, MELVILLE, President and Engineer, General Radio Co., Cambridge, Mass.

ENGLE, MELVIN D., Engineer, Station Engineering Dept., Edison Electric Illuminating Co. of Boston, Boston, Mass.

EVANS, ROBERT D., General Engineer, Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa.

FRIEND, HENRY M., Cable Engineer, Hugh L. Cooper & Co., New York, N. Y.

GARY, LAURENCE A., Engineer, Transmission Dept., Pacific Tel. & Tel. Co., San Francisco, Calif.

HASTINGS, MILTON B., Vice-President, Powerlite Devices, Ltd., Toronto, Ont.

INNES, FRANK R., Asst. Editor, *Electrical World*, New York, N. Y.

KERSEY, GLEN B., Field Engineer, Commonwealth Edison Co., Chicago, Ill.

McDOWELL, H. E., Electrical and Mechanical Engineer, Texas Power & Light Co., Dallas, Tex.

NASH, JOHN F., Electrical Engineer and Division Manager, Appalachian Power Co., Bluefield, W. Va.

RADER, RAY, Assistant Engineer, Puget Sound Power & Light Co., Seattle, Wash.

ROBERTS, SPENCER, Engineer, Day & Zimmerman, Philadelphia, Pa.

SCOFIELD, EDWARD H., Engineer of Power, Twin City Rapid Transit Co., Minneapolis, Minn.

SMITH, GEORGE S., Instructor of Electrical Engineering, University of Washington, Seattle, Wash.

VANHALANGER, L. J., Sales Engineer, Westinghouse Electric & Mfg. Co., Chicago, Ill.

WAY, HOWARD E., Special Agent, Electrical Equipment Div., Bureau of Foreign and Domestic Commerce, Washington, D. C.

WREAKS, HUGH T., Manager, Detroit Office, Boston Insulated Wire & Cable Co., Detroit, Mich.

APPLICATIONS FOR ELECTION

Applications have been received by the Secretary from the following candidates for election to membership in the Institute. Unless otherwise indicated, the applicant has applied for admission as an Associate. If the applicant has applied for direct admission to a higher grade than Associate, the grade follows immediately after the name. Any member objecting to the election of any of these candidates should so inform the Secretary before February 28, 1926.

Aaroe, E., Electric Bond & Share Co., New York, N. Y.

Alger, C. S., Puget Sound Power & Light Co., Seattle, Wash.

Allschwager, O. A., Northern States Power Co., Minneapolis, Minn.

Altamirano, S. E., General Electric, S. A., Mexico D. F., Mex.
(Applicant for re-election).

Anderson, D. P., Western Electric Co., Chicago, Ill.

Anderson, W. B., Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.

OFFICERS OF A. I. E. E. 1925-1926

President
M. I. PUPIN

Junior Past Presidents
FARLEY OSGOOD HARRIS J. RYAN

Vice-Presidents
HAROLD B. SMITH P. M. DOWNING
EDWARD BENNETT HERBERT S. SANDS
JOHN HARISBERGER W. E. MITCHELL
L. F. MOREHOUSE ARTHUR G. PIERCE
H. W. EALES W. P. DOBSON

Managers
H. M. HOBART JOHN B. WHITEHEAD
ERNEST LUNN J. M. BRYANT
G. L. KNIGHT E. B. MERRIAM
WILLIAM M. McCONAHEY M. M. FOWLER
W. K. VANDERPOEL H. A. KIDDER
H. P. CHARLESWORTH E. C. STONE

National Treasurer
GEORGE A. HAMILTON

National Secretary
F. L. HUTCHINSON

Honorary Secretary
RALPH W. POPE

LOCAL HONORARY SECRETARIES

T. J. Fleming, Calle B. Mitre 519, Buenos Aires, Argentina, S. A.
Carroll M. Mauseau, Caixa Postal No. 571, Rio de Janiero, Brazil, S. A.
Charles le Maistre, 28 Victoria St., London, S. W. 1, England.
A. S. Garfield, 45 Bd. Beausejour, Paris 16 E, France.
H. P. Gibbs, Tata Sons Ltd., 24 Bruce Road, Bombay—1, India.
Guido Semenza, 39 Via Monte Napoleone, Milan, Italy.
Eiji Aoyagi, Kyoto Imperial University, Kyoto, Japan.
P. H. Powell, Canterbury College, Christchurch, New Zealand.
Axel F. Enstrom, 24a Grefturegatan, Stockholm, Sweden.
W. Elsdon-Dew, P. O. Box 4563, Johannesburg, Transvaal, Africa.

A. I. E. E. COMMITTEES

(A list of the personnel of Institute committees may be found in the January issue of the JOURNAL.)

GENERAL STANDING COMMITTEES AND CHAIRMEN

EXECUTIVE, M. I. Pupin
FINANCE, G. L. Knight
MEETINGS AND PAPERS, E. B. Meyer
PUBLICATION, L. F. Morehouse
COORDINATION OF INSTITUTE ACTIVITIES, Farley Osgood
BOARD OF EXAMINERS, Erich Hausmann

EDUCATION, Harold Pender
ELECTRICAL MACHINERY, H. M. Hobart
ELECTROCHEMISTRY AND ELECTROMETALLURGY, George W. Vinal
ELECTROPHYSICS, J. H. Morecroft
INSTRUMENTS AND MEASUREMENTS, A. E. Knowlton
APPLICATIONS TO IRON AND STEEL PRODUCTION, F. B. Crosby
PRODUCTION AND APPLICATION OF LIGHT, Preston S. Millar
APPLICATIONS TO MARINE WORK, L. C. Brooks
APPLICATIONS TO MINING WORK, F. L. Stone
GENERAL POWER APPLICATIONS, A. M. MacCutcheon
POWER GENERATION, Vern E. Alden
POWER TRANSMISSION AND DISTRIBUTION, Percy H. Thomas
PROTECTIVE DEVICES, E. C. Stone
RESEARCH, John B. Whitehead

A. I. E. E. REPRESENTATION

(The Institute is represented on the following bodies; the names of the representatives may be found in the January issue of the JOURNAL.)

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE, COUNCIL
AMERICAN BUREAU OF WELDING
AMERICAN COMMITTEE ON ELECTROLYSIS
AMERICAN ENGINEERING COUNCIL
AMERICAN ENGINEERING STANDARDS COMMITTEE
AMERICAN MARINE STANDARDS COMMITTEE
AMERICAN YEAR BOOK, ADVISORY BOARD
APPARATUS MAKERS AND USERS COMMITTEE
BOARD OF TRUSTEES, UNITED ENGINEERING SOCIETY
CHARLES A. COFFIN FELLOWSHIP AND RESEARCH FUND COMMITTEE
COMMITTEE ON ELIMINATION OF FATIGUE, SOCIETY OF INDUSTRIAL ENGINEERS
ENGINEERING FOUNDATION BOARD
JOHN FRITZ MEDAL BOARD OF AWARD
JOINT COMMITTEE ON WELDED RAIL JOINTS
JOINT CONFERENCE COMMITTEE OF FOUR FOUNDER SOCIETIES
LIBRARY BOARD, UNITED ENGINEERING SOCIETY
NATIONAL FIRE PROTECTION ASSOCIATION, ELECTRICAL COMMITTEE
NATIONAL FIRE WASTE COUNCIL
NATIONAL MUSEUM OF ENGINEERING AND INDUSTRY, BOARD OF TRUSTEES
NATIONAL RESEARCH COUNCIL, ENGINEERING DIVISION
NATIONAL SAFETY COUNCIL, ELECTRICAL COMMITTEE OF ENGINEERING SECTION
THE NEWCOMEN SOCIETY, RADIO ADVISORY COMMITTEE, BUREAU OF STANDARDS
SOCIETY FOR THE PROMOTION OF ENGINEERING EDUCATION, BOARD OF INVESTIGATION AND COORDINATION
U. S. NATIONAL COMMITTEE OF THE INTERNATIONAL ELECTROTECHNICAL COMMISSION
U. S. NATIONAL COMMITTEE OF THE INTERNATIONAL ILLUMINATION COMMISSION
WASHINGTON AWARD, COMMISSION OF

A. I. E. E. SECTIONS AND BRANCHES

See the January issue for the latest published list. The Institute now has 50 Sections and 84 Branches.

DIGEST OF CURRENT INDUSTRIAL NEWS

NEW CATALOGUES AND OTHER PUBLICATIONS

Mailed to interested readers by issuing companies

Switchboards.—Bulletin 111, 4 pp. Describes "Ideal" switchboards and synchronous motor starting panels. The Ideal Electric & Mfg. Company, Mansfield, O.

Blowers.—Bulletin 1608, 16 pp. Describes "ABC" pressure blowers and exhausters. American Blower Co., Detroit, Mich.

Steam Turbine Generators.—Bulletin GEA-54, 44 pp. Principally a photographic presentation of the Curtis turbine as installed in notable power plants, ranging up to 60,000 kw. General Electric Co., Schenectady, N. Y.

Safety Switches.—Catalog, 56 pp., entitled "Westinghouse Safety Switches," describes industrial, motor starting and meter service switches. Westinghouse Electric & Mfg. Company, East Pittsburgh.

Switchboards.—Bulletin No. 1006-2, 16 pp. Describes construction and pictures installations of Condit switchboards in various industries. Condit Electrical Mfg. Corporation, Boston, Mass.

Automatic Switching Equipment.—Bulletin GEA-295, 24 pp. Describes the application of automatic switching equipment to railway service, hydro-electric generators, mining, industrial, central station service, etc. General Electric Company, Schenectady, N. Y.

Rail Bond Testers. Bulletin 200, 8 pp. The Type BBT bond tester and Type B contact bar described are new devices just placed on the market. The particular application of the new tester lies where the current on the rail is very feeble, or absent altogether. The sensitivity of the new device is claimed to be five times as great as any heretofore made. It can be used with the current from a single No. 6 dry cell. Roller-Smith Company, 12 Park Place, New York.

Automatic Direct-Current Starter.—Bulletin 215, 4 pp. Describes Type C-1220 current limit automatic d-c. starter, for use in starting constant speed shunt or compound wound motors up to 30 h. p., 115 volts; and 50 h. p., 230 or 500 volts, for any applications where it is desired that the time of acceleration correspond with the load on the motor. **Crane, Hoist and Mill Controller.** Bulletin 330, 8 pp. Describes Type F-2250 controllers, for general crane and mill service. Allen-Bradley Company, Milwaukee, Wis.

NOTES OF THE INDUSTRY

Simplex Wire & Cable Company, Boston, has opened a branch office in the Union Trust Building, Cleveland, in order to better care for a steadily increasing volume of business. William H. Lamond will be manager of the new office.

Kohlenite Products Company, Inc., New York, manufacturer of carbon brushes, has opened a branch office located at 1555 Monadnock Block, Chicago. This office will be in charge of H. A. Hallead.

The Griscom-Russell Company has moved its general offices in New York to the new Murray Hill building, 285 Madison Avenue.

The Foxboro Company, Inc., Foxboro, Mass., maker of indicating, recording and controlling instruments, has moved its Pittsburgh office from the Park Building to what will now be known as the Foxboro Building, located at the corner of Sixth Avenue and Grant Street. The four upper floors will be utilized for offices and the maintenance of a substantial stock of new equipment.

130,000 Kilowatts to be Added to Detroit Power Supply.—Three turbine generators, totalling 130,000 kilowatts in capacity, are to be added to the facilities of the Detroit Edison Company. Two of these machines, 50,000 kw. each, will be placed in the Trenton Channel station, and the other, 30,000 kw., in the Marysville station. The turbines are being made by the General Electric Company and will be delivered within eight months.

Largest Lighting Contract to Westinghouse.—What is said to be the largest contract for street lighting equipment ever placed, consisting of 10,000 standard lighting units, reflectors and auxiliary equipment, was recently awarded to the Westinghouse Electric & Mfg. Company through the Ryckoff Construction Company of Chicago for a new street lighting system for the City of St. Louis. A plant will be erected in St. Louis for delivery of the hollowspun concrete poles at the rate of 1000 each month, as required by the contract.

General Radio Company Promotions.—At the annual meeting of the company on January 12, the position of Chairman of the Board of Directors was created to meet the growth of the company. Henry S. Shaw, Treasurer for the past eight years, was elected to this position. H. B. Richmond, formerly Secretary and Assistant Treasurer, was elected to the position of Treasurer. No other changes were made in the officers; Melville Eastham who has served as President for the past eleven years will continue in that office and E. H. Locke enters his sixth year as Vice-President, in charge of manufacturing. During the past year the company completed its new factory at Cambridge, Mass., which provides 50,000 square feet of ideal manufacturing space.

Master Electric Sales Conference.—On January 11 and 12 the branch office representatives and the distributing agents of The Master Electric Company met at the factory, Dayton, Ohio, for a sales conference. The primary object of the meeting was to acquaint the field organization with the greatly increased facilities offered by the new plant at Linden and Master Avenues and into which the company just recently moved. On the evening of January 11 the visiting representatives and a number of plant executives held a banquet at the Engineers Club.

General Electric Orders for 1925.—Orders received by the General Electric Company for the year ending December 31, 1925, amounted to $302,513,380, according to an announcement by Gerard Swope, president of the company. Compared with $283,107,697 for the year 1924, this is an increase of seven per cent. For the three months ending December 31, 1925, orders totalled $78,636,669, compared with $80,009,978 for the same quarter of 1924, a decrease of two per cent.

Sales Organization Changes in W. N. Matthews Corporation.—Louis M. Meckler has succeeded W. J. McIlvane as New York representative of the W. N. Matthews Corporation, St. Louis, manufacturers of Matthews electrical specialties. The Baltimore territory, which was formerly covered by Mr. McIlvaine, will be under the supervision of H. C. Biglin, southern district manager of the corporation. J. T. Pearson, district manager in Detroit, has resigned and this territory will be covered by H. L. Brueck, Chicago district manager. The Iowa territory which was formerly covered by Mr. Brueck will be taken care of by W. M. Watters. The northern section of Pennsylvania, which has been covered by the New York office, has been transferred to J. A. Jaques of the Pittsburgh office.

J. H. Bunnell & Company Changes Hands.—Control of J. H. Bunnell & Company, founded in 1879 and known as one of the world's leading manufacturers of high-grade telegraph apparatus; also as manufacturers of fire alarm apparatus and other electrical equipment, has been acquired by J. J. Raftery and J. G. Dougherty. Mr. Raftery was previously connected with the Western Electric Co., and later with Manhattan Electrical Supply Co., Inc., as Eastern General Manager. Mr. Dougherty was formerly with the Illinois Steel Corporation. The retiring President, J. J. Ghegan, who has been associated with Bunnell for forty years, will retain a financial interest in the business and will continue to give it the benefit of his long experience. Plans for expansion are being worked out.

Intellectual Renaissance in America*

Idealism found its clearest expression in the men who immediately after the Civil War had inaugurated a new epoch in American history, the epoch of the *intellectual renaissance in America.* It was the epoch of the new movement in the direction of higher endeavor in all intellectual, aesthetic and spiritual activities of our national soul. Joseph Henry, Barnard, White, Draper, Eliot, Lowell and many other intellectual leaders led the movement, but it took its first concrete form in Baltimore, when Johns Hopkins University was formally opened fifty years ago.

The wisdom of the trustees of the princely gift which a modest Baltimore merchant had placed into their hands was that of inspired men when they selected Daniel Coit Gilman as the interpreter of the wish of Johns Hopkins.

The quality of the men whom Gilman selected for his original faculty proclaimed this idealism. Sylvester, the mathematician; Gildersleeve, the Grecian; Morris, the classicist; Remsen, the chemist; Rowland, the physicist, and Martin, the biologist, were the members of the original faculty over which the genius of Gilman presided. This was the famous heptagon, a new constellation of seven brilliant stars in the intellectual firmament of America.

Associated with this constellation there were other young and brilliant stars like Brooks, Elliott, Adams and Scott. No finer group of idealists was ever assembled in any university faculty. But their idealism was not that of a vague and misty type.

A knowledge of the truth which uplifts the soul of man and makes it free was always a part of the gospel of Johns Hopkins University. Gildersleeve's ancient classics and Remsen's modern chemistry; Sylvester's and Cayley's abstract mathematics and Welch's concrete science of medicine; Martin's modern physiology and Haupt's language of ancient Babylon; Rowland's latest theories in physics and Johns Hopkins' inquiries into the earliest documents of the Christian creed; Lowell's discourse on Dante and Brook's story of the Chesapeake oyster; Huxley's evolution and Dean Stanley's theology; Kelvin's structure of the vibrating atom and Sidney Lanier's structure of the sonorous verse—all these sources of God's eternal truth were welcome topics to the gospel which was proclaimed in the lecture rooms of Johns Hopkins University. It thrilled the American intellect as it had never been thrilled before.

I can pass over in silence many discoveries in mathematics, physics, chemistry, physiology, biology and other branches of knowledge; they are very important and well understood by the experts. But there are three achievements which have a great national significance, and they are not all as well understood by our nation as they ought to be. These I must describe, even if briefly.

The first great achievement of national significance which I must mention is the Johns Hopkins Medical School. Thirty years ago I was told by a great medical authority in London that the Johns Hopkins Medical School is second to none and that its professors and former pupils are the prophets of the medical profession. I found out later that the names of Welch, Osler, Halstead and Kelly were household words in the medical profession.

The ideals of the university were the same as those of its medical school. Welch, the first dean of the medical school, and his colleagues were guided by the same idealism which guided Gilman and his famous heptagon.

I must now mention another achievement of great national significance. The modern American medical school did not exist before William H. Welch became the dean of the Johns Hopkins Medical School; neither did the American university exist before Daniel Coit Gilman became president of the Johns Hopkins University.

But there is an achievement which is of even greater national significance than the two that I have just mentioned. Nothing is as difficult as molding the mental attitude of men; the average mind has an enormous inertia. There was a time when the so-called practical man had little use of the idealist of the Johns Hopkins heptagon type. The movement in the direction of higher endeavor, with its lofty ideals, gave no thrill to the prosy soul of the practical man.

The American industries controlled by the stubby hand of the practical man had no points of sympathetic contact with the subtle touch of science of the research laboratory. But presently industrial problems arose which were too scientific for the practical man. The harnessing of Niagara Falls and the electrification of the New York subways, for instance, were too much for the practical man. Rowland, the idealist, and Duncan, his pupil, had something to say on this subject and they received a respectful hearing. It was found that their

*Abstract of an address at the fiftieth anniversary of Johns Hopkins University on Feb. 22, 1926.

scientific idealism had a practical side, just as Brook's idealism in biology had a practical side when he told the biological story of the Chesapeake oyster.

Pretty soon the practical man opened the door of his industries and welcomed the disciples of the John Hopkins heptagon of idealists. Their idealism gave birth to the idealism of the American university research laboratories, and from these it moved into American industries. The scientific idealism which Rowland and his colleagues preached is today the idealism of our industrial research laboratories.

The words uttered lately by three distinguished American engineers are still ringing in my ears; they are the words of Jewett, Durand and Hoover. Their ideas are accepted everywhere as the practical ideas of practical men. What is their message? It is this: The greatest need of this nation is thorough training and research in the fundamental sciences. But this was the gospel of Johns Hopkins fifty years ago, and it is today. The adoption by the practical engineer of the creed of this gospel is one of the greatest services of Johns Hopkins to our nation.

My old friend President Goodnow and his distinguished colleagues are making every effort not only to continue this national service but even to amplify it. Our nation never needed it more than it does at the present moment.

M. I. PUPIN.

Some Leaders of the Institute

Gano Dunn, the twenty-fourth president of the Institute, was born in New York City, October 18, 1870. He attended the College of the City of New York, from which he was graduated with the B. S. degree in 1889; he also received the degree of M. S. from that institution in 1897. In 1891 he received the E. E. degree from Columbia University, and honorary M. S. from Columbia in 1914.

His professional work began in 1886, in the service of the Western Union Telegraph Company, where he remained five years. He then entered the service of the Crocker-Wheeler Company, at Ampere, N. J., and from 1898 until 1911 was vice-president and chief engineer of that company. In the latter year he was elected vice-president in charge of engineering and construction by the J. G. White Company, and in 1913, when the J. G. White Engineering Company was organized to take over the engineering and construction work of the parent company, Mr. Dunn was made president, in which position he still continues.

From 1900 until 1902, Mr. Dunn was president of the New York Electrical Society. He was president of the A. I. E. E. throughout the term 1911-12; president of the United Engineering Society from 1913 to 1916; of the John Fritz Medal Board of Award in 1914; the Engineering Foundation 1915-16, and vice-chairman of the National Research Council, 1917, afterwards becoming chairman.

He is the author of various important papers on engineering subjects, and has served on many important technical committees and boards.

Mr. Dunn was secretary of electric lighting and distribution, for the International Electrical Congress, St. Louis, 1904, and a delegate and vice-president of the International Electrical Congress, Turin, 1911. He is a member of the International Electrotechnical Commission, and in 1916-18 was a member of the Engineering Committee of the Council of National Defense; also, during the war he was chairman of the State Department Committee on submarine cables.

He is a member of several American and foreing technical and engineering societies, beside belonging to various clubs in the United States and a broad.

Companies Encouraging Convention Attendance

More organizations are realizing the advantages of having interested members of their forces attend the meetings of professional societies such as the Institute. The benefits of such attendance are felt not only by the individuals but they are carried back to the parent companies in the form of increased information, broader viewpoint, greater enthusiasm and development of personality.

As a matter of fact many companies appreciate these benefits to such an extent that they make it the duty of some members of their staff to attend certain features of conventions. They realize the importance of encouraging the attendance of their members in order that they may gain technical knowledge from the reading and discussion of the papers and from inspection trips, and that they may develop their characters through informal conversation with others at the meeting and through the social functions.

This practise certainly indicates a healthy state of mind and shows a far-sightedness of managers and managements which is entirely commendable.

Auxiliary Radio Language

The recently held International Conference of Radio Amateurs, at Paris, France, appointed a committee to study and report upon the problem of an auxiliary language for use in communication, correspondence and conversation between members of the International units of the organization. About twenty artificial languages were considered, including Esperanto and Ido, as well as a few national languages. After considerable debate, in which the Scandanavian representatives strongly urged the adoption of English as the approved auxiliary language, the committee reported in favor of Esperanto.

A High-Frequency Voltage Test for Insulation of Rotating Electrical Apparatus

BY J. L. RYLANDER[1]
Member, A. I. E. E.

***Synopsis.**—For many years the need for a higher test voltage between turns of individual coils or complete windings has been recognized. To obtain this higher test voltage, high frequency has been introduced. The high frequency used for this test is produced by damped oscillating discharge from a condenser and applied directly to the leads of the coil or winding. Practically any desired voltage can be applied to a coil or winding provided a sufficiently high frequency is used.*

As a shop method for checking defects in material, or poor workmanship, the high-frequency test method has been found very effective in those classes of windings so far tried.

The method used for detecting short circuits on the principle of the radio receiving set are described.

INSULATION is used on rotating electrical apparatus to insulate between its various parts which have a difference of potential and also to insulate all parts of the circuit to "ground." The "ground" insulation is thoroughly tested by the present method of applying a high potential, usually at normal frequency, between the winding and the core or frame at various stages of construction. The present methods of testing the insulation of various parts of the same circuit such as from one turn to other turns, one layer of wire to other layers of wire, are far from adequate. It is the purpose of this paper to present a method of making a thorough and practical test between various parts of a coil or winding.

Present Method of Test

The present method of testing between turns and layers of coils consists of placing the coil over a pole piece magnetized by a primary coil which induces a voltage in this coil as the secondary coil of a transformer. The maximum voltage that can be induced by this method will not exceed 10 or 20 volts per turn in most coils as the voltage is limited by the size of pole piece that can be inserted into the opening of the coil and to the frequency of the circuit. Usually 133 or 500 cycles per second are used. This test discovers short circuits where there is actual copper to copper contact. However, it does not discover any weak or damaged insulation where there is not actual copper contact. Therefore many coils are given no insulation test.

The windings of d-c. armatures are tested by this same induction method by revolving the armature slowly and testing each coil separately. This test discovers any short circuits caused by actual copper to copper contact and also discovers open circuits. As this type of testing apparatus is only adaptable for rotating windings, induction motor primary windings are not given this test.

The completed motor or generator is given a running test with rated voltage for one-half hour to several days depending on the test data needed. This test is applied to the motor when new and operating at normal voltage and under normal conditions of operation. It makes no allowance for future deterioration of the insulation or for any abnormal conditions of operation.

In order to obtain a higher test voltage between turns of coils both before and after winding the coils in the machine, that would be considered a real insulation test, high-frequency voltage is applied directly to the terminals of the coil or windings.

Types of High Frequency

With high frequency, advantage can be taken of the inductance of the coil or winding and thus obtain almost any voltage desired.

The use of high frequency for various test purposes is not new but as far as the author is aware it has not been applied to the commercial testing of individual coils and wound apparatus.

In general, there are two types of high-frequency voltage; (1) undamped oscillations and (2) damped oscillations. The first type includes the high frequency voltage produced by high frequency generators which is, comparatively speaking, limited as regards the range of frequency. This class may also include the high frequency produced by vacuum tubes, such as used in radio work and which has a very high range of frequency compared to any generator.

The second type is produced by the oscillating discharge of a condenser through an inductance with a comparatively low resistance.

The production and control of both types of high frequency has been known practically and theoretically for many years and is described in many text books on radio and physics so no detailed description need be given.

The oscillating discharge high frequency was chosen for commercial test purposes because of its comparative ease of production and control.

It may be of interest to enumerate briefly a few of the experiments which were made with other types of high frequency. The reason for these experiments was mainly that when the damped oscillating high frequency

---

1. Electrical Engineer, Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa.

Presented at the Midwinter Convention of the A. I. E. E., New York, N. Y., February 8-11, 1926.

was first put in use the spark-gap was the only practical means of measuring the voltage. As is well known, the measurement of voltage with the sphere spark-gap is not very accurate under 2000 or 3000 volts. Inasmuch as there were many cases where a lower high frequency test voltage was desired attempts were made to measure the damped oscillating voltage by other means than spark-gap. Ordinary voltage measuring instruments were entirely unsuitable and it was also found, as was anticipated even before trial, that the electrostatic voltmeter would not give the correct measurements.

At this point, therefore, attempts were made to use the undamped high frequency obtained from vacuum tubes. However, the necessary frequency from this source was so high that it was difficult to screen the indicating instruments from the indirect effect, so this also was discarded for commercial reasons.

The high-frequency voltage obtained from a high frequency generator was next resorted to but the current required up to 5000 cycles was so high that serious heating occurred in the bands of banded armatures in the case of direct-current machines.

In the meantime methods of detecting short circuits on wound apparatus, including commutating machines, were developed. This development permitted the high frequency test voltage to be applied across the normal span of the brushholders on a commutating machine, so the necessity for very low voltage at high frequency was largely removed. Later, also a method of instrument measurement of damped high-frequency voltage was developed, and for this reason all efforts were finally concentrated on the damped high-frequency test voltage.

The Principle of Operation of the Damped High-Frequency Set

A very high voltage can be applied to any winding if the frequency is sufficiently high. The voltage drop due to the inductive reactance is $E = 2 \pi f L I$ where f is the frequency per second and L is the inductance in henries and I is the current in amperes. For example, a 15-turn circular coil with a 12-in. diameter having a d-c. resistance of 0.1 ohm and an inductance of 0.001 henry would have approximately the following voltages across its terminals with 10 amperes in the circuit: one volt d-c.; 4 volts, 60 cycles per second, and 4000 volts with 60,000 cycles per second. It is thus seen that practically any desired voltage can be placed across a coil or a winding if sufficiently high frequency is applied. The voltage is applied by connecting the two leads from the high frequency apparatus directly to the terminals of the coil or winding either partial or completely finished.

When high frequency is applied to the apparatus under test, it sets up an alternating electromagnetic field of a particular frequency in a manner similar to a radio transmitter. If a short circuit occurs in the winding, the wave length and frequency will be changed accordingly, and the strength of the outgoing signals is reduced. A wave meter is used to measure the outgoing waves and thereby determine whether any insulation failure has occurred.

The wave meter consists of a set of inductance coils, variable condenser with a vernier attachment, two variable resistances and a low reading ammeter of the thermo-element type, all connected in series with one of the inductance coils. The inductance coils are such that by changing the setting of the variable condenser, resonance may be obtained for the frequency generated by the coil or winding under test. The condenser, the ammeter and the variable resistances are mounted on a panel and a tuning coil is placed near the apparatus being tested. The tuning coils have low resistance and a minimum capacity for a given inductance. Coils with taps are unsatisfactory on account of the end-turn loss.

The wave meter is tuned to the frequency of the waves omitted by the apparatus under test and it acts in a manner similar to a radio receiving set. A current flows in the wave meter circuit which is measured by the ammeter. The variable condenser is adjusted until a maximum current is shown on the meter which thereby indicates the condition of resonance and also the frequency of the circuit. The meter reading alone does not mean anything in particular; it is the relative meter readings used in connection with the condenser readings and the distance from the tuning coil to the apparatus under test which tells the story.

The principle by which high frequency is produced by this outfit is that a condenser placed across the secondary terminals of the transformer is charged during each alternation of the 60-cycle current. The condenser is automatically discharged through rotating disks when the voltage reaches a predetermined value on each alternation. The discharge of the condenser through the apparatus under test produces a high-frequency current whose frequency is determined by the apparatus under test and the capacity of the condenser.

Description of High-Frequency Testing Apparatus for Commercial Use

The high-frequency testing apparatus consists essentially of (1) equipment for generating the high frequency and applying it to the apparatus under test, and (2) a means of detecting any short circuits or failures in the insulation of the apparatus under test while the high frequency is being applied. A photograph of the apparatus is shown in Fig. 1. A schematic diagram of this apparatus in shown in Figs. 2A and 2B, Fig. 2A showing the generation of the high frequency and its application to the coil or winding and Fig. 2B showing the apparatus used in the detection of an insulation failure.

The power is furnished by a transformer of 10-kw. capacity with 7500-15,000 and 30,000 volts on the secondary. A 70 per cent reactance limits the current to one and a third times full-load current with the short-

circuit current in the secondary. The condensers have a capacity of 0.05 microfarads at 30,000 volts. The air-gap for discharging the condenser is formed between two motor-driven rotating brass alloy disks so that the arc across the gap will not burn the metal. The sphere-gap limits and measures the voltage across the apparatus under test. A resistance of 15,000 ohms is placed in series with the sphere-gap to prevent the spheres from being burned by the arc. For voltages of 5000 and

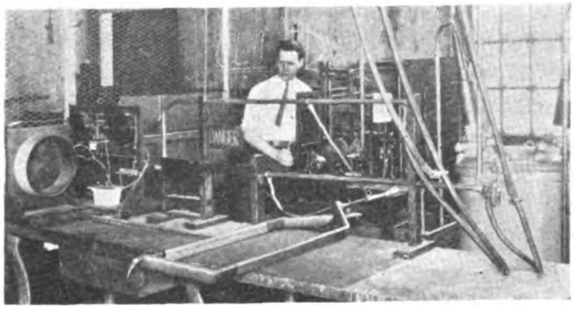

FIG. 1

higher, five-cm. spheres are used, and for lower voltages one-cm. spheres are used, also instrument measurement. A panel contains switches for the circuit breaker and plugs for tapping in different values of reactance. A hand-wheel is used for controlling the spacing of the gap of the rotating disks. Voltages ranging from 2000 to 30,000 volts can be obtained with this particular apparatus. By a combination of series and parallel connections the transformer will give 7500, 15,000 or 30,000 volts and intermediate voltages are obtained by adjustment of the rotating gap.

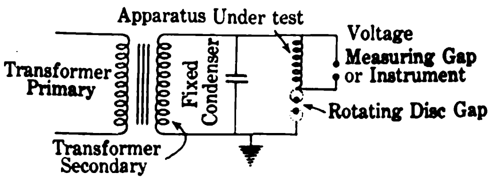

FIG. 2A

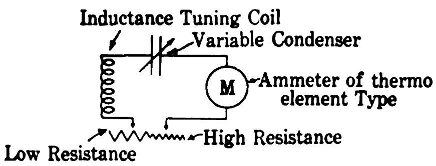

FIG. 2B

The manipulation of the test apparatus consists of connecting the leads to the coil or winding under test and setting the sphere-gap for the value corresponding to the desired test; then closing the circuit breaker and opening up the rotating disk gap until the desired voltage is obtained. This is indicated by a spark across the measuring gap. The voltages are generally applied for from 10 to 15 seconds. The frequency is determined by the apparatus under test usually within the limits of 10,000 to 200,000 cycles per sec. for individual coils and 5000 to 100,000 cycles per sec. for wound apparatus.

THE HIGH-FREQUENCY VOLTAGE

The damped high-frequency voltage as produced by this set gives a somewhat more severe test on the insulation than a corresponding voltage at normal frequency. Fortunately such a test can be used to discover faults without damage to the normal insulation.

In general the voltage builds up somewhat on the end coils. At first thought this may seem to be a disadvantage, but in actual service the end coils of a group are subjected to greater voltage in the case of surges than are the other coils. The voltage on the inner coils is sufficiently high, however, to give an adequate test for defects in material or workmanship.

VALUE OF TEST VOLTAGES USED

The high-frequency test voltage applied to the terminals of wound apparatus corresponds closely to the regular ground test as given by the A. I. E. E. standards. This allows a liberal margin of safety over the strain due to operation at its normal voltage, and also to the momentary high voltage, high frequency surges that may be impressed in service.

The voltage which it is desirable to apply to individual coils before winding into a machine is largely a question of judgment based on experience. We have used successfully on induction regulator coils a test voltage on single coils somewhat higher than the operating voltage of the machine for voltages lower than 2500 volts while for voltages over 2500, a test voltage somewhat lower than the operating voltage, has been used.

METHODS USED IN TESTING WITH HIGH FREQUENCY

The methods used for various types of apparatus are somewhat different, depending on various conditions. The method of testing a single coil is shown in Fig. 1.

The method of testing the windings of a two-pole, single-phase, induction regulator is shown diagrammatically in Fig. 3 for the stator and Fig. 4 for the rotor. The two leads from the high frequency set are connected to leads *A* and *B* of one pole and the tuning coil of the wave meter is placed alongside the frame as shown at *C*. The voltage is applied for 10 to 15 seconds. The two high frequency leads are then connected to the leads *E F* of the other pole of the winding and the tuning coil placed at *G*.

The high-frequency leads can be connected to three-phase machines by either of the methods shown in Figs. 5 to 8 inclusive.

The high-frequency leads may be connected either across each pole-phase group as shown in Fig. 5, or from each lead to the star connection, as illustrated in Fig. 6 or across the leads as in Figs. 7 and 8. Each of these connections have merits for certain conditions as determined by the number of poles, the voltage of the

machine, the number of turns in the winding, the number of parallel connections and the size of the machine.

On a d-c. armature the voltage is applied at two

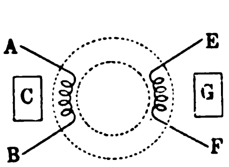

Fig. 3—Two-Pole Single-Phase Stator Winding

points on the commutator corresponding to the location of the brushes, and the armature is then rotated.

The tuning coil of the wave meter is placed in the

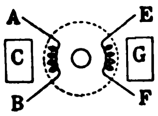

Fig. 4—Two-Pole Single-Phase Rotor Winding

most advantageous position which usually is close to the outside circumference of rotors and either inside the bore or outside the frame of stators.

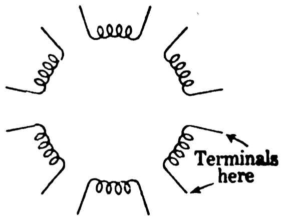

Fig. 5—Voltage Applied to each Group Separately

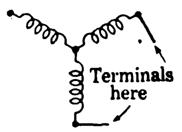

Fig. 6—Voltage Applied to Each Phase Separately

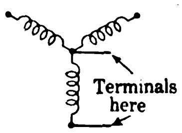

Fig. 7—Voltage Applied Across Two Terminals of a Star Connected Winding

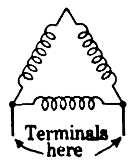

Fig. 8—Voltage Applied Across Two Terminals of a Delta-Connected Winding

For each coil and winding the wave meter settings are recorded. These settings show both the frequency and the strength of signal transmitted from any particular apparatus when the winding is normal and free from faults. As each coil or winding is tested, the readings will correspond to the standard readings if the winding is free from faults, but if short-circuited, different readings will be obtained. It is thus easy to check any apparatus that has been previously tested. If new, the approximate readings can usually be estimated with sufficient accuracy by comparing the general characteristics of the windings with other known windings, and checking one part of the winding with another is an additional check. The fact that a short circuit has a deadening effect on the radiations transmitted as well as changing the wave length and frequency facilitates the discovery of any short circuits.

Scope of Application

This method of insulation testing was first applied commercially in the testing of induction regulator coils. The results were so satisfactory that the test was extended to the wound regulators, both stators and rotors of single-phase and three-phase regulators. Thousands of induction regulator coils for machines of all voltages up to 14,000 volts and hundreds of wound primaries and wound secondaries are now being tested each month with high frequency. The development has now reached a point where completely wound d-c. armatures, a-c. generator coils, turbo-generator coils and wound induction motors either partly or completely connected have been tested experimentally.

Considerable experimental work must be done before this method can be applied safely as a commercial shop test to complete windings of large alternators or induction motors. For example, sufficient information as to satisfactory test values is not yet available to apply high frequency voltage as a test to the complete windings which will be a proper measure of their ability to withstand surges in operation.

Benefits Derived from High Frequency Testing

Testing coils and windings with high frequency has had an effect on the insulation of the apparatus to which this test is applied. It showed that insufficient insulation for reliable operation was used in some cases, that different kinds of material should have been used in others, that certain insulating materials had been badly crushed during one of the coil forming operations, that the vacuum impregnation had not fully penetrated to all parts of the coil and that the moisture had collected into these spots and that the insulation used on certain designs was too liberal. It also furnished a good idea as to whether the insulation was sufficiently balanced between the various turns and layers to withstand the natural uneven voltage distribution that occurs in coils and windings whenever the windings are subjected to surges and line disturbances. It is thus seen that high frequency testing has enabled the improvement of the insulation of the windings by eliminating

weak or defective coils, which might otherwise have been used. High frequency also checks the ability of the insulation to withstand the occasional severe dielectric strains that will occur in service and to which at present so many of the otherwise unaccountable insulation failures are attributed.

Test Results

As induction regulator coils have been tested regularly for over four years some of the results of these tests will be of interest. During the first two years 5 per cent of all coils tested failed to stand the prescribed test but the weekly percentage of failure varied from 1 per cent to 30 per cent. During the past year the percentage failures varied from 0 to 2 per cent weekly with an average of 1 per cent. This great reduction in the number of coils that failed to stand the test was accomplished by correcting the cause of the trouble which can usually be determined by a thorough examination. However, if these coils had not been rejected on account of the high frequency test, all of the coils would otherwise have been used, as none of the coils had any defect that could have been discovered by any other method than high frequency testing.

A record of the complete windings that have been tested shows that out of 100 machines of a certain particular type there were no failures, but on other types there were as high as 10 per cent and an average of all the types of 1 per cent. It is not to be inferred that the faults detected by this test would all have resulted in service failures. The applied test has purposely been made severe in order to certainly weed out all weaknesses of this class.

There has been a distinct improvement in these machines from the service standpoint. Whereas, there was a considerable number of failures, before high-frequency testing was started on these coils, there has not been reported a single insulation breakdown in service of any machine on which high-frequency test had been applied to the coils or the winding.

High-Frequency Testing Meets A Great Need

High-frequency testing shows up poor workmanship, checks the insulation design and the processes of manufacture. It insures that proper and adequate insulating materials are in their proper place and not missing or damaged and that no harmful foreign materials are present. It checks up such features as the elimination of moisture and the thoroughness of impregnation, undue mechanical pressure at any point and the ability of the materials to stand the mechanical operations of coil construction, and whether the various materials are sufficiently uniform.

All of the above conditions may exist but they may not be detected or discovered without the aid of high frequency testing as they are hidden from view and visual inspection is useless.

One real merit of high-frequency testing is that it invariably shows the cause of the failure, as the arc is of only such intensity as to burn out the weak insulation without burning the copper. When a machine fails in service the opposite nearly always occurs, as the copper is usually so badly burned as to destroy all evidence of the cause of the insulation failure.

High-frequency testing has now reached a stage of development where it is used as a shop test on some classes of apparatus as a check on manufacturing processes. The author does not wish to convey the idea that a point has been reached where the method may be applied as a universal commercial test.

ULTRAVIOLET RADIATIONS

For years the scientists have attempted to make artificial sunlight and to apply it to achieve the marvels of nature; they have delved into the actual sunlight and determined its constituents; they have studied radio-activities in nature and have utilized electrical phenomena. As a result the world has a great variety of new light waves to apply. Of these the ultraviolet rays so frequently encountered from electric arcs have long been known. Much erroneous matter about the ultraviolet-ray effects has been published, but at the present time a truly astonishing list of useful applications exists.

Control of the reactions of many gases and of several chemical reactions has been achieved. In photochemical and photolytic reactions the ultraviolet ray has an important place. It is effective in halogenation reactions and in sterilization. A real field has been found in applications to biology and therapeutics, and it has come to have a very great commercial importance for industrial work in testing and bleaching.

The ultraviolet ray is applied to bring quick aging and testing of industrial materials; it detects the fastness of dyes and the quality of inks. It can be used to dry oils and leather and to determine the durability of coatings such as paints. In many bleaching operations the ultra-violet radiations are useful and they can be used to vulcanize rubber, to test the quality of paper, to waterproof paper and to detect impurities in food products.

In the field of mineral and metal fluorescent studies lie a large number of commercial possibilities, and even the cold light so eagerly sought may at last be found through the use of these radiations. Researches of many kinds are continuing, and in the near future it should be possible to reconcile and summarize a vast number of data on ultraviolet applications. It has been proved beyond doubt that this radiation from electric arcs, once considered only as an element deleterious to eyesight, is a very useful industrial and scientific tool.—*Electrical World.*

Rating of Heating Elements for Electric Furnaces
Test Data and Integration of Interference Between Resistors

BY A. D. KEENE[1] AND G. E. LUKE[1]
Associate, A. I. E. E. Associate, A. I. E. E.

Synopsis.—*A study of the practical considerations involved in assigning kilowatt ratings to radiant heating elements in furnace chambers. Constants for radiation and absorption are given. Consideration is given to shape and spacing of elements with respect to shielding due to adjacent elements. A method of determining the equivalent unshielded element is worked out to provide a basis for comparing dissimilar shapes of heaters.*

* * * * *

THE failure of an electric-furnace heating element is usually due to the chaotic methods used in establishing its ratings. Frequently heating elements are given arbitrary ratings, with no analysis of the conditions under which they are to operate. Some designers have developed rule-of-thumb methods of rating elements, based on current density, or on energy dissipated per unit area. Many of these methods are further elaborated to allow for increased ratings at low chamber temperatures. These methods must be used with considerable caution as they are almost invariably based on experience with only one type of heating element, used under restricted conditions. The determination of the general constants involved has been hampered by the cost of making scientific measurements at high temperatures. A general formula must provide for the following variables:

1. The physical characteristics of the heating surfaces.
2. The relative spacing and location of the component parts of the heating surfaces.
3. The allowable difference in temperature between the element surface and the surrounding atmosphere.

Data and mathematical analysis, made available within the last year, give these constants and make it possible to determine factors of safety of various shapes and arrangements of heating elements, and so make direct comparisons. This will permit the heating engineer to select his units with greater freedom and predict the temperatures at which they will operate. The calculation is analogous to the calculation of the mechanical engineer, who determines the unit stress on the extreme fiber of the beam he is loading with a fairly accurate knowledge of the stress at which it may be expected to fail.

A conductor supported in air, and carrying electric current will increase in temperature until the heat removed by conduction, convection, and radiation, equals the heat generated within the conductor by the passage of the current. This is true whether the conductor is inclosed in a furnace chamber to act as a source of heat, or is a part of a transmission line where heat is an undesirable by-product. The relative amounts of heat removed by the three different means of transmission change rapidly with the operating temperature of the conductor.

The convection loss from a surface increases as the $1\frac{1}{4}$ power of the difference in temperature between the surface and the surrounding room, while the radiation loss increases as the fourth power. At a surface temperature of 1000 deg. cent. (1832 deg. fahr.), the loss from a conductor in free air is roughly 90 per cent by radiation and 10 per cent by convection. (Conduction through air is so small as to be negligible and will be disregarded throughout the remainder of this article.) At this temperature, it is evident that an air space is a very inefficient heat insulator, since 90 per cent of the energy travels freely and almost without loss between the enclosing surfaces.

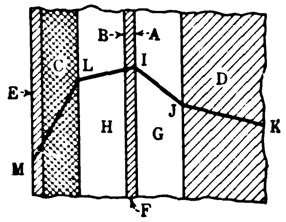

FIG. 1

The simplest heating element might be a sheet of resistance material covering an area of furnace wall and parallel to the wall, the arrangement being as indicated in Fig. 1, F is the plate in which heat is generated with surface A toward, and parallel to the charge D which is to be heated, and surface B toward, and parallel to wall C which is a partial heat insulator. We will consider F, a large thin plate so the losses from the edges may be eliminated as negligible. Heat generated in the plate is conducted to the surfaces A and B. We will assume that wall C is of such material and thickness that 20 per cent of the heat generated in the plate escapes to the outside. Surface B can then dispose of only 20 per cent of the energy, generated so surface A must attain such a temperature as to dispose of the remaining 80 per cent of the energy. Surfaces A and B are opposite sides of a thin plate and so are at approximately the same temperature. When a state of equilib-

1. Both of the Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa.

Presented at the Midwinter Convention of the A. I. E. E., New York, N. Y., February 8-11, 1926.

rium of heat-flow is reached, the temperature-gradients will be approximately as represented by lines I–J–K and I–L–M, the temperature at the surface of the wall L will be considerably higher than the temperature J at the surface of the charge because the difference in temperature between I and J is forcing four times as much heat across the space G as the difference in temperature between I and L is forcing across the space H.

It is particularly noticeable in this example that all surfaces of an element are not equally effective in disposing of the generated heat. If we consider surface A as 100 per cent effective, we can then consider the surface B only 25 per cent effective because under operating conditions it disposes of only one-fourth as much of the generated heat. The surfaces of plate F as located are then only 62.5 per cent as effective in disposing of heat as they would be if charge D were disposed on both sides of plate F. The factor 62.5 per cent (in this case) may be called the "surface efficiency" since it is the factor by which the total surface area of the resistor must be multiplied to obtain the area of an equivalent resistor whose surface is 100 per cent effective.

Theory and Experimental Data

(*a*) *Single Linear Heater.* Due to the relatively poor thermal conductivity of the supporting refractories, and to the small area of contact, very little heat is conducted away from the heater elements. Hence radiation and convection are the principal agents in the transfer of heat from the elements. The fundamental equation, expressing the rate of heat dissipated by radiation and convection from surfaces, is:

$$W = a(T_2 - T_0)^{1.25} + 36.9\,e\left[\left\{\frac{T_2}{1000}\right\}^4 - \left\{\frac{T_1}{1000}\right\}^4\right]$$

Where

- W = Watts dissipated per sq. in. of surface
- T_2 = Absolute temperature deg. cent. of heater surface
- T_0 = Absolute temperature deg. cent. of room or furnace air
- T_1 = Absolute temperature deg. cent. of surrounding surfaces
- a = Convection constant
- e = Coefficient of emissivity (1.00 for a black body)

In the above equation, the convection loss is shown as proportional to the 5/4th power of the temperature rise of the heater above the ambient air. The radiation loss, however, increases at a much greater rate, since it is a function of the fourth power of the absolute temperatures. The constants (a) and (e) vary slightly with the temperatures; however, the variation is so small that it can be neglected for practical purposes. The values of these constants were determined from experimental tests. The single linear heater element was suspended in free air. The input was measured electrically and the final temperatures were determined by the use of thermo couples. An optical pyrometer was also used to check the heater temperatures. The thermo couples were 0.008-in. diameter platinum and platinum-rhodium spot welded to the conductor.

From the large number of tests made, average values of the constants were obtained as follows:

Heater Element	Constant (a)	Constant (e)
¼-in. diameter nickel chromium...........	0.0032	0.91
¾-in. wide strip nickel chromium..........	0.0013	0.90

Using these constants in the equation previously given, the curves shown, Fig. 2, were plotted. Experimental tests on this curve covered the range of 100 to 1100 deg. cent. The elements were tested both vertically and horizontally and very little difference was found, especially at commercial temperatures where most of the heat is transmitted by radiation.

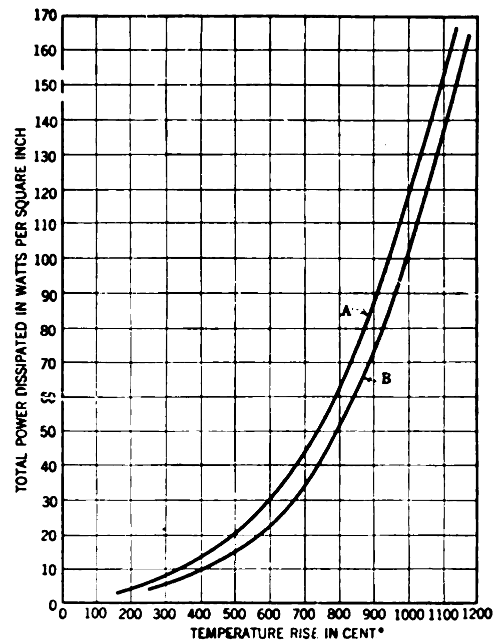

Fig. 2

A = ¼-inch rod
B = 1⅕-inch wide strip
Ambient temperature 27 deg. cent.

(*b*) *Parallel Heater Elements—Single Row.* In a commercial furnace, the heater consists of a large number of parallel ribbons or rods. It is evident that the rating of such elements will not be as great as a single element, due to interference of the adjacent elements. For such parallel heater elements arranged in a row, the relative heat loss can be calculated on the basis of the angle subtended by the opposite interfering resistor. Thus, in Fig. 3 is shown a row of parallel strip resistors. The approximate radiation from any small element ($d\,x$) will be proportional to the ratio of (180 deg. $- \alpha$) per 180 deg. An integration of these elements, either mathematically or graphically, over the total surface will give the effective radiation. Results

of such calculations are given in Figs. 5 and 6 for round rods and strips respectively. The curves are plotted in terms of ratios in order to be applicable to any particular arrangement and size of heating element. While these curves as calculated refer only to radiated energy, tests show that they also represent very closely the effectiveness of the surface for both radiation and convection. The reason for this primarily is due to the relatively small amount of heat lost by convection —although it is a fact that by the grouping of the elements the convection and radiation losses are reduced to about the same degree. These curves were experimentally checked throughout the range shown, both round rods and strips being used. In making these tests, three equally spaced parallel elements were used. Thermo couples were placed on all three. Means were provided for independently varying the current through the middle heater and the two outside heaters. In this way the current was adjusted so as to give equal temperatures for all three heaters. The loss from the middle conductor was measured.

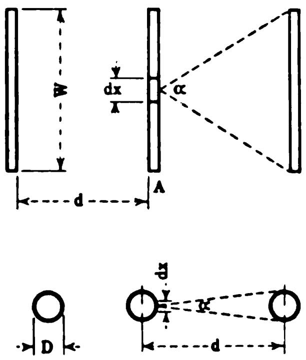

FIG. 3

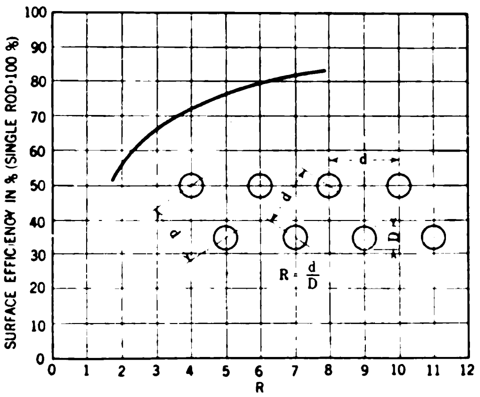

FIG. 4—CURVE OF SURFACE EFFICIENCY FOR DOUBLE BANKED RODS

(c) *Parallel Heater Elements—Double Row.* In some furnaces it is desirable to double bank the heating elements. The two rows of elements will interfere to some extent so that the rating will be reduced. The "surface efficiency" of a double bank resistor composed of round parallel rods arranged equidistant from each other, was calculated in the same manner as the single bank. The calculated curve is shown in Fig. 4.

The curves Figs. 4, 5, and 6 show values of surface efficiencies plotted against the ratios of spacings to widths and diameters respectively. The curves are not directly comparable as the abscissas are not expressed as ratios of similar dimensions.

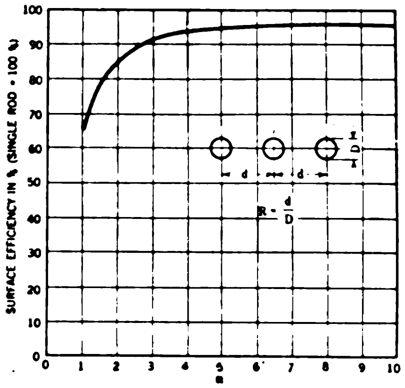

FIG. 5—CURVE OF SURFACE EFFICIENCIES FOR RODS

It is interesting to analyze commercial heating elements on the basis of the above data.

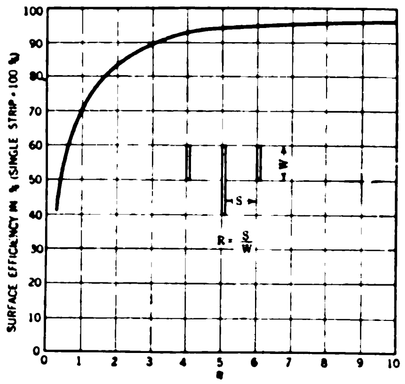

FIG. 6—CURVE OF SURFACE EFFICIENCIES FOR STRIPS

Let us assume the following conditions:

1½ in. wide strip 1/10 in. thick spaced, 1½-in. centers arranged as in Fig. 3, 0.289 in. diameter rod 1-in. centers arranged in two layers, (double banked) as shown in Fig. 7, and 0.289-in. rod ¾-in. centers single layer (single banked) also shown in Fig. 3. In each case power, equivalent to 15 watts per square inch of radiating surface, is generated in the element. The furnace chamber temperature is fixed at 900 deg. cent. (1652 deg. fahr.). Room temperature 27 deg. cent.

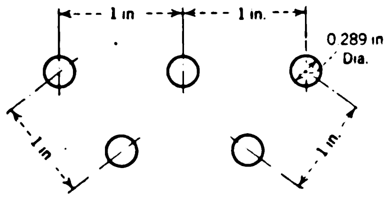

FIG. 7—ARRANGEMENT OF FURNACE HEATING ELEMENT RODS

We will assume that the resistor enters the danger zone, in which oxidation becomes progressive and, therefore, destructive at 1100 deg. cent. (2012 deg. fahr.).

For the Case of the Double-Banked Rod

d = 1-in.
D = 0.289
R = 03.46

The surface efficiency from Fig. 4 is then 70 per cent.

Then 15 watts per sq. in. is equivalent to 15 ÷ 0.70 = 21.43 watts per sq. in. dissipation.

To use the curves in Fig. 2 at furnace chamber temperatures, we must transpose from 27 deg. cent. ambient temperature to 900 deg. cent. ambient temperature as follows:

900 deg. − 27 deg. = 873 deg. which corresponds to 78 watts on the Curve A for rods (Fig. 2).

Then 78 + 21.43 (the equivalent dissipation determined above) = 99.43 watts which corresponds to a temperature rise of 950 deg. cent. (Curve A, Fig. 2). The operating temperature of the rod is then 950 deg. cent. + 27 deg. cent. = 977 deg. cent.

If 1100 deg. cent. marks the entrance to the danger zone, a 12.6 per cent rise in temperature will be required to bring the temperature of this heating element up to a dangerous value. This 12.6 per cent may then be considered as the factor of safety.

In the Case of the 1½ in. Ribbon

W = 1½
S = 1½ − 1/10 = 1 4/10
R = 0.933

Surface efficiency = 69 per cent from Fig. 6.

Then the dissipation equivalent to 15 watts per sq. in. = 15 ÷ 0.69 = 21.74 watts per sq. in.

900 deg. cent. minus 27 = 873 deg. cent. which corresponds to 65 watts dissipation on Curve B, Fig. 2.

65 watts + 21.74 = 86.74 watts per sq. in. This is equivalent to a 960 deg. cent rise. The operating temperature is then 960 deg. cent. + 27 deg. cent. = 987 deg. cent.

This gives a factor of safety as above of 11½ per cent.

For the Single Banked Rod

d = 0.75
D = 0.289
R = 2.6

From Fig. 5 the surface efficiency is 89.5. Then the dissipation equivalent to 15 watts per sq. in. is 15 ÷ 89.5 = 16.65.

900 − 27 deg. cent. = 873 deg. cent. which corresponds to 78 watts on Curve A, Fig. 2. Then 78 + 16.65 = 94.65 watts per sq. in. which corresponds to a temperature rise of 930 deg. cent. The operating temperature of the rod is then 930 deg. + 27 deg. = 957 deg. cent. This gives a factor of safety of 14.94 per cent.

It should be noted that these factors apply only to the physical conditions specified. A narrower ribbon or smaller rod would have a higher factor of safety for this spacing. A wider strip would have a considerably lower factor of safety as we are working on the steep part of the surface efficiency curve, Fig. 6.

We may also make an analysis of the cost of metal required to generate one kilowatt of heat energy in a furnace chamber. Let us assume the same conditions of physical size and spacing as were used in the preceding illustration, the operating temperature of the resistor 1000 deg. cent. and the furnace chamber temperature 900 deg. cent.

Considering the Double Banked Rod

The dissipation of energy at 100 per cent surface efficiency on a rod at 1000 deg. cent. is 106 watts per sq. in. (from Curve A, Fig. 2). The dissipation at 900 deg. cent. (chamber temperature) = 79 watts per sq. in. correcting for 27 deg. ambient temperature in each case.

The difference is 27 watts per sq. in. or the permissible dissipation from a rod having 100 per cent "surface efficiency."

The double banked rod as before is 70 per cent efficient so the actual watts permissible dissipation is 70 per cent of 27 = 18.9 watts per sq. in.

To dissipate 1000 watts will require 1000 ÷ 18.9 = 52.91 sq. in. of rod surface.

The area of one foot of .289 in diameter rod is 10.9 sq. in.

52.91 ÷ 10.9 = 4.854 linear feet of rod required weighing 0.239 lb per foot = 1.16 lb.

At a list price of $4.05 per pound this is $4.80 for the cost of double banked rod to dissipate one kilowatt.

For the Strip

The watts per sq. in. dissipation at 100 per cent surface efficiency on a strip at 1000 deg. cent = 92 from Curve B, Fig. 2.

At 900 deg. cent. = 65 (correct for 27 deg. ambient temperature).

The difference is 27 watts per sq. in. permissible dissipation from a strip having 100 per cent "surface efficiency."

The strip as before is 69 per cent efficient so the actual watts permissible is 69 per cent of 27 = 18.6 watts per sq. in. and to dissipate 1000 watts will require

1000 ÷ 18.6 = 53.8 sq. in.

The area of one linear foot of strip is 38.4 sq. in.

53.8 ÷ 38.4 = 1.4 linear feet of strip weighing 0.81 lbs. per foot = 0.782 lbs. at $5.10 per pound = $3.99 for the cost of strip to dissipate one kilowatt.

In the Case of the Single Banked Rod

The dissipation from a 100 per cent surface efficiency rod as in the case of the double banked rod is 27 watts per sq. in.

The efficiency as in the earlier single banked rod example is 89.5 per cent so the actual watts permissible is 89.5 per cent of 27 = 24.16.

To dissipate 1000 watts will require 1000 ÷ 24.16 = 41.35 sq. in. of heater area.

The area of a linear foot of 0.289 inch diameter rod is 10.9 sq. in.

41.35 ÷ 10.9 = 3.793 feet of rod at 0.239 pounds per foot this weighs 0.9065 lb. at $4.05 per pound = 0$3.67 for the cost of single banked rod to radiate one kilowatt.

In computing the above costs prices have been listed for nickel chromium as quoted by a well-known manufacturer. As in the case of efficiencies, other physical dimensions will materially change the results. The dimensions used are those of heating elements in common use.

For convenience, the results of the above problems are tabulated below:

Shape of element	Arrangement of element	Factor of safety at 15 watts per sq. in. dissipation	Cost of metal per Kw. radiated at constant factor of safety
Strip 1½ in. wide	Single banked Fig. 3	11½ per cent	$3.99
Rod 0.289 in. dia.	Single banked Fig. 3	14.94 per cent	$3.67
Rod 0.289 in. dia.	Double banked Fig. 7	12 6 per cent	$4.80

The above problems serve to illustrate several important points in design.

1. A resistor element of any shape may be supported in a furnace and so rated as to give a suitable factor of safety and reasonable service.

2. The shape of the element does not inherently insure a lower first cost of material. (Low cost frequently sacrifices a part of the factor of safety).

3. The selection of the elements for any furnace is an engineering problem requiring proper analysis. It should be approached with the idea of applying a suitable heating equipment, not with the idea of adopting some specific type of element to the installation.

In the foregoing calculations, we have disregarded the effect of adjacent walls. This should not introduce a serious error where the element itself is not so located as to act as a screen preventing reradiation and reflection of heat energy from the wall. The wall would perhaps have considerable effect on convection currents, but convection plays a relatively small part in the dissipation of heat at these temperatures.

Heat radiated to the wall is either reflected or is absorbed by the wall. That absorbed is conducted away from the surface or re-radiated into the furnace chamber. For the relative values of these various heat transfers, we must again refer to test data available. Fire brick at a temperature of 1000 deg. cent. reflects 40 per cent of the radiant heat falling on its surface and absorbs the other 60 per cent. If 50 per cent of the heat generated finds its way to the wall surfaces as radiant energy, then 20 per cent of the heat generated in the furnace is reflected from the walls much as light is reflected from a mirror. Thirty per cent is absorbed by the walls. If one-half of this heat absorbed is conducted to the external surface and lost, the remainder, 15 per cent of the heat generated in the heating elements, is re-radiated from the walls into the furnace chamber.

Thus, it can be seen that with the above data, the furnace engineer can calculate with reasonable accuracy the temperatures attained by resistor elements in service and can determine the factors of safety. He can also anticipate the manner in which heat will be transmitted to the charge. These calculations are of utmost importance to the furnace buyer. The fact that the conditions in a projected furnace can be determined by competent engineers, much as the loading of a bridge is determined, is insurance against loss through furnace failure.

A REAL CONTRIBUTION TO KNOWLEDGE OF STABILITY

System stability has been a debatable subject for several years. The advocates of transient stability and those of static stability have argued for their respective criteria for system performance in many papers and meetings. Data on an actual system, however, have been unavailable until lately, and the discussions have waxed warm on the basis of the relative importance different specialists attached to assumed factors.

It is encouraging to find that executives of the Pacific Gas & Electric Company consented to submit the system of that company to a series of stability tests for the benefit of the whole industry. In his paper before the meeting of the American Institute of Electrical Engineers this week Roy Wilkins gave the results of the tests and made available to all properties many valuable data. The executives and engineers of the Pacific Gas & Electric Company have thus contributed greatly to the development of the art, and it is to be hoped that tests by other utilities covering data needed to develop other phases of the art will likewise be published for the benefit of the industry instead of being merely placed on file on dusty shelves.

The normal limit, or even rating, of a power system is difficult to define because of the ever-changing electrical and physical conditions in lines, equipments and loads. For a specific system, however, both the static and transient stability limits can be agreed upon and determined quite accurately for given conditions. Thus progress has been made. Debates on technicalities and attempts to generalize about stability should not be permitted to obscure this fact.—*Electrical World.*

Operating Performance of a Petersen Earth Coil-II

BY J. M. OLIVER[1] AND W. W. EBERHARDT[1]

Associate, A. I. E. E. Associate, A. I. E. E.

Synopsis.—*At the A. I. E. E. Spring Convention, Pittsburg, April 24-26, 1923, a paper was presented by the authors on the operation of a Petersen Earth Coil installed by the Alabama Power Company on its Lock 12-Vida 44,000-volt system. That paper reported an excellent performance record for the coil, although several unaccounted for bus insulator flashovers occurred at Lock 12, indicating that further investigations on the action of the coil were necessary.*

This paper presents eleven months' additional operating experience with the Earth Coil, which shows that over-voltage disturbances can be eliminated by doing all line switching operations with the Petersen Coil out of service; that is, with the system neutral solidly grounded. It is believed that the same results can also be obtained by under-tuning the coil.

The Lock 12 Coil is no longer in service, as the system has outgrown the need of such equipment; additional power sources have been added to the system and reliable service can be maintained without the use of flashover suppressing devices.

It appears that the application of Petersen Earth Coils is limited to comparatively low voltage lines (66,000 volts and less) of moderate length with a single source of power supply. In such an application, the use of a Petersen Coil between system neutral and ground has the advantage over grounded neutral operation by reducing line outages due to flashovers and over isolated neutral operation by eliminating arcing grounds.

* * * * *

The purpose of this paper is to present eleven months' additional operating experience with the Alabama Power Company's Petersen earth coil installed on its Lock 12-Vida 44,000-volt system, shown in Fig. 1. A detailed description of this installation is given in the writers' earlier paper[2] presented at the A. I. E. E. Spring Convention, Pittsburgh, April 24-26, 1923. A complete operating log of the Lock 12 coil for the period extending from October 12, 1921 to March 1, 1923 was also given in that paper, which showed an excellent performance for the coil, the number and duration of interruptions due to lightning flashovers having been reduced by 83.5 and 94 per cent respectively, by its use. There were, however, several unaccounted for bus insulator flashovers at Lock 12, which indicated that further investigations on the action of the coil were necessary.

The bus insulator flashovers in question occurred when the line switch at Lock 12 opened automatically or was opened by hand while the Petersen coil was in service. It was the consensus of opinion of those who discussed the Pittsburgh paper that the high-voltage flashovers were caused by the non-simultaneous opening of the three poles of the line breaker. This is a very plausible explanation of the trouble because at that time the coil was overtuned,—that is, it had excess reactance—and the disconnection of one line conductor ahead of the other two would change the line capacitance in the right direction to produce a condition of resonance in the series circuit, in which case there would be nothing to limit the rise of voltage except the system losses. Assuming that this is the correct explanation for the high-voltage disturbances, there are two remedies which can be applied; namely (a) to undertune the coil, and (b) to electrically interlock the control circuit of the grounding switch with the overload protective relay scheme on the line switch so that the grounding switch is always automatically closed before the line switch opens to clear phase-to-phase short circuits.

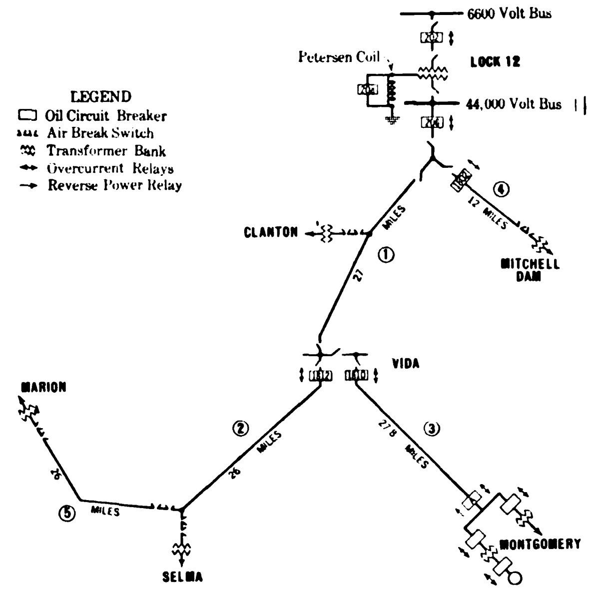

Fig. 1—Lock 12—Vida 44, 00-Volt System

Of these two methods, (a), if successful, would prove the more advantageous since no change in the normal control connections is required. Method (b) has the disadvantage of introducing complications in the control scheme and also slows up the relay operations on phase-to-phase short circuits, since additional timing must be allowed for the closing of the ground switch. Method (b), however, had already been applied and was in operation when the theory of undertuning was advanced so it was decided to continue operation with the interlocking feature between the ground and line

switches during the 1923 lightning season, and then perhaps operate the coil under-tuned during the 1924 season. Unfortunately, the coil had to be taken out of service before the 1924 lightning season for reasons stated in the latter portion of this paper, and the under-tuning principle of operation thus far has not been given a trial.

Operation with Interlock Between Line and Ground Switches

Fig. 2 is a connection diagram of the complete control equipment on the Lock 12 Petersen coil, the interlocking of the grounding switch control circuit with the

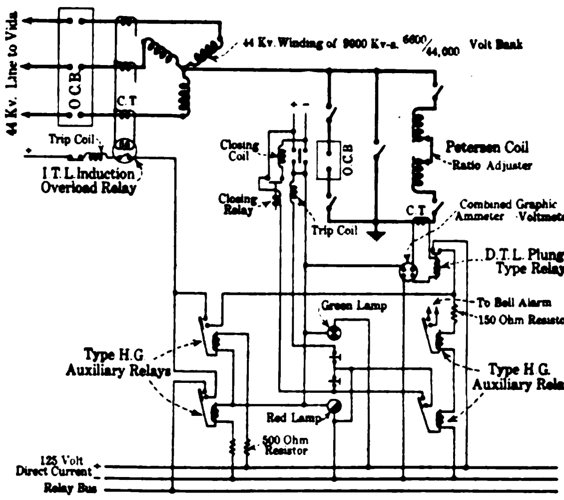

Fig. 2—Lock 12—Petersen Coil Installation—Schematic Diagram of Connections

protective relay scheme on the line switch being accomplished by the use of the two type *H G* auxiliary relays shown in the lower left hand corner of the diagram. Operators were also given instructions to always close the neutral grounding switch; that is, to take the Petersen coil out of service before doing any line switching. The Lock 12 coil operated under this new operating procedure from February 24, 1923 to January 26, 1924, during which time no further high-voltage disturbances were experienced, indicating that a satisfactory solution to the problem had been found.

A complete log of all the operations was taken during the period mentioned and summary of these operations is given in Table I which shows the following results:

Flashovers. There was a total of 109 insulator flashover indications recorded on the combined graphic ammeter and voltmeter, 94 of which, or 86 per cent, did not result in line interruptions and are considered perfect operations of the Petersen coil.

On the remaining fifteen flashover indications the line switch opened causing an interruption to service. In each case, however, the line was promptly put back into service, O. K., indicating that the trouble was not a solid ground, but rather a flashover which the Petersen coil failed to clear. These operations are therefore considered faulty.

Solid Grounds and Phase-to-Phase Short Circuits. There was a total of five solid grounds and 21 phase-to-phase short circuits, due to line and transformer troubles. These cases of trouble were outside of the operating sphere of the Petersen coil, but in each case the line overload relays functioned properly and promptly to clear the disturbance.

Interruptions to Lock 12-Vida Line Due to all Causes. Table II is a classification of service interruptions to the Lock 12-Vida line from March 1, 1923 to January 26, 1924, exclusive of prearranged interruptions and those due to trouble on other parts of the Alabama Power Company's system. This tabulation shows that there was a total of 40 interruptions to service with a total outage of 221 minutes for this eleven months' period, which is a far better service record than was obtained for any previous period of similar duration.

TABLE I

SUMMARY OF PETERSEN COIL OPERATIONS.[1]

Month	Flashover Indications				Transformer Trouble		Line Trouble	
1923	Under 6 Amperes	Over 6 Amperes	Faulty Operation of Coil Line Switch Opened	Switch 208 Closed but no Interruption	Phase-to-ground	Phase-to Phase	Phase-to-Ground	Phase-to-Phase
March	—	2	1	-	1	-	-	-

Total	23	55	15	16	1	2	4	19

Total number of operations...........135

1. Copies of the complete log from which this Summary was compiled may be obtained from the authors on request.

This service record is especially remarkable for a long radial feeder when it is taken into consideration that 144 minutes of the total time out were due to a single case of trouble when a tree fell into the line.

Since the function of the Petersen coil is to reduce the interruptions due to lightning, a comparison of service interruptions to the Lock 12-Vida line chargeable to lightning for the years 1922, 1923 and 1924 proves very interesting as the following tabulation will show:

TABLE II

INTERRUPTIONS ON LOCK 12-VIDA 44-KV. SYSTEM MARCH 1, 1923 TO JAN. 26, 1924.
(Exclusive of Interruptions due to Trouble on Other Parts of Alabama Power Cmpany's System.)

Year	Method of Operation	Number of Lightning Storms Over Line	Interruptions due to Lightning	
			Number	Total Time Out
1922	System neutral solidly grounded	82	43	230 minutes
1923	Neutral grounded through Petersen Coil	97	7	14 minutes
1924	Ditto	80	22	41 minutes

This tabulation shows that although approximately the same number of lightning storms have occurred in the vicinity of Lock 12 each year, the interruptions due to lightning were greatly reduced while the Petersen coil was in service, proving its effectiveness in suppressing flashovers.

LIMITATIONS IN USE OF THE LOCK 12 COIL

The Lock 12 coil was taken out of service and the system neutral solidly grounded January 26, 1924, because

(a) At that time the line mileage of the Lock 12-Vida system was practically doubled by the addition of new lines, making the total line charging current greater than the Petersen coil was designed for and to take care of which would have required new taps on the coil, and

(b) A generating station was added at Upper Tallassee which was connected to the system through a delta-star transformer bank with a solidly grounded neutral on the 44,000-volt winding.

Of course, a second Petersen coil could have been introduced between the Upper Tallassee neutral and ground since on a Petersen coil system a reactor must be installed at each grounding point; but with two sources of power supply to Lock 12-Vida system, it was felt that reliable service could be maintained at Montgomery without the use of Petersen coils and their expense was, therefore, not justified. It was also foreseen

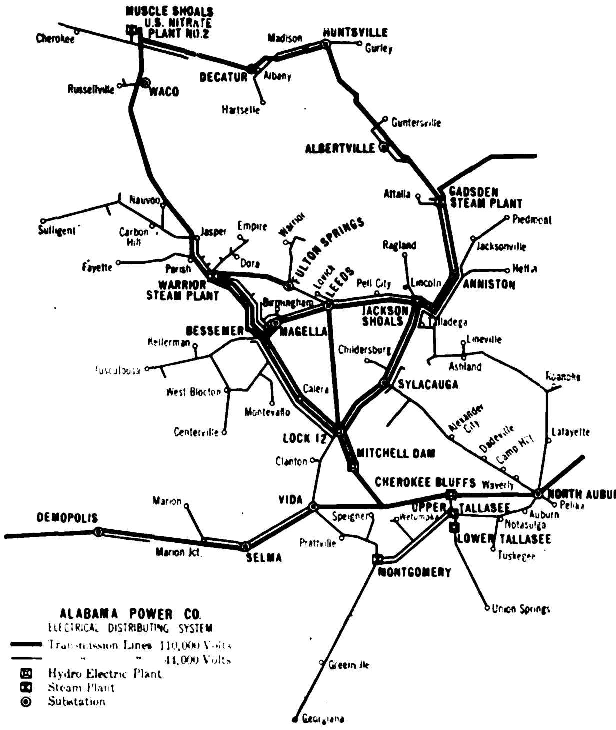

FIG. 3

that the Lock 12-Vida system would be further extended and linked with the Alabama Power Company's main 44,000-volt network, which is solidly grounded at Warrior, Bessemer, Leeds, Jackson Shoals and Anniston substations. This interconnection was completed in the

latter part of 1924 and the 44,000-volt system network now exists, as shown in Fig. 3.

CONCLUSIONS

The Alabama Power Company's experience with the Petersen earth coil indicates that it will greatly reduce the number of interruptions due to insulator flashovers during lightning storms.

All high-voltage disturbances which were experienced when the coil was first placed in service have been entirely eliminated by making provisions to do all line switching, both hand and automatic, with the coil out of service—that is, with the system neutral solidly grounded.

The application of Petersen coils appears to be limited to comparatively low-voltage lines (of 66,000 volts and less) of moderate length, with a single source of power supply. On an interconnected network, such as the Alabama Power Company now operates, several sources of supply are maintained to all principle load centers and good service can be carried on without the use of flashover suppressing devices. In other words the expense and complications of a Petersen coil installation are justified only on radial feeder systems where it is desired to improve service to an important load center which is connected to the power source by only a single line. The Petersen coil in such an application has the advantage over grounded neutral operation by reducing line outages due to flashovers and over isolated neutral operation by eliminating arcing grounds.

LAKE MERRIT HAS SPECIAL LIGHTING

Equipping streets and exteriors of public buildings with special electric lighting is now quite common, but doing this to a lake is a different story. In fact, Lake Merritt, Oakland, Cal., is probably the only one of its kind which has such electric lighting.

Around the shore of the lake there are now special electric lamp posts from each of which hang Gothic lanterns provided with amber glass. Each of the lanterns has a reflector so adjusted that a large portion of the lantern light will fall on the surface of Lake Merritt. In addition to these, electric floodlight units have been placed around the lake to illuminate clumps of shrubbery and groups of trees and also between the lamp posts, concrete sockets have been put in place so that for special celebrations poles carrying festoons of streamer lights may readily be put in place.

All of this electric lighting is controlled from a single central switch house where there is equipment which makes it possible to dim the light of the various lamps to such an extent that the filament of each is only a dull red. Then within a minute by turning the gears these lamps are once more producing their full candlepower of light. With all this lighting Lake Merritt on ordinary nights is a sight worth seeing and when dressed up for special occasions it is a veritable fairyland that attracts people from far and wide.

THE COMPARISON OF NATURAL AND ARTIFICIAL LIGHTING

In connection with the efforts that are now being made to trace the relation between better lighting and higher efficiency of work, it is natural that experimenters should try to base their conclusions on the results achieved by daylight.

The greater part of the work of the world is still done by natural light, and a comparison between natural and artificial lighting conditions affords much interesting information. It is doubtful, however, whether all investigators realize the complexity of the factors involved in such a comparison. The illumination available by the best daylight conditions is far greater than is usually furnished by artifiical means. On the other hand, daylight is a highly variable quantity. Photometric measurements show that remarkable changes may occur even during a relatively short working period. In making comparisons, the experimenter is usually driven to adopt as a measure the *average* daylight illumination during the working period. But it is questionable whether an average between illuminations varying, perhaps, in a ratio of 10 to 1 can be regarded as a measure of the effective daylight illumination. The eye is inevitably affected by these changes, and it would seem better, in making comparisons, to devise some method (*e. g.*, by adjustment of blinds) by which the actual daylight illumination can be kept practically constant during the test period.

Again, the *nature* of daylight illumination, as well as the intensity, may be quite different from artificial light. The presence of the bright sky overhead out of doors causes corresponding adaptation of the eye, and leads it to demand illuminations much higher than might otherwise be required. Even in a room the presence of a window near at hand, through which the sky can be seen, has a similar effect.

Taking all these facts into consideration, it is not surprising that quite different answers are often received to the simple question: "Does one require more or less illumination by natural light than by artificial light?" The whole subject is one that deserves careful investigation, and would furnish material for an interesting discussion. Meantime there is one obvious lesson—investigators who attempt to make comparisons between artificial and natural lighting should be careful to specify as exactly as possible the daylight conditions in the room in which the comparison is made. Daylight illumination is not under our control, but an increase in artificial lighting involves corresponding increased cost. If standards recommended to consumers are unnecessarily high, a reaction towards economy and a set-back to future progress may occur. Supply undertakings could, however, materially smooth the path towards higher illuminations by closer co-operation and reduced rates.—*The Illuminating Engineer.* (London).

Mechanical Force Between Electric Circuits

BY R. E. DOHERTY[1] and R. H. PARK

Associate, A. I. E. E. — Non-member

Synopsis.—A general equation is developed for the mechanical force exerted by a system of n electric circuits, upon any part of that system. The electric circuits are assumed to contain resistances, and the reluctance of the several magnetic circuits is assumed to be a function of both the currents and the relative positions of the circuits. The equation is therefore applicable to circuits involving saturated iron.

Special cases of a single circuit and of n circuits are treated, in which a method of graphical solution is given. Also an approximation is made, which results in fairly simple analytical expressions for the force in the case of circuits involving saturated iron.

The results are preliminary to an investigation of the forces existing in synchronous machines under the condition of short circuit, which subject will be treated in a forthcoming paper.

I—Discussion of Problem and Method of Solution

ALTHOUGH methods have been available for calculating the force of an electromagnet, or between simple circuits of constant inductance, such as reactance coils containing no iron, nevertheless general methods have not, to the authors' knowledge, been developed for calculating the force exerted between dissimilar circuits which contain iron and which therefore have magnetic reluctances that may vary both with the magnetic density and the relative position of the circuits. It is the purpose of the present paper to offer methods for these cases. The work presented here, as well as that in a forthcoming paper in the near future, is largely the result of an investigation made by one of the authors in 1922 on the mechanical forces in synchronous machines under short circuit conditions.

Historical

The basic contributions regarding the mechanical force exerted by electro-magnetic circuits were, of course, made by Ampere[2], Kelvin and Maxwell[3]; and the greater part of the subsequent development of the subject has been the application of their fundamental equations to particular cases.

Maxwell's equation for the "mechanical action between two circuits" is, in different notation,

$$f_x = \frac{1}{2} I_1^2 \frac{d L_1}{d x} + I_1 I_2 \frac{d M}{d x} + \frac{1}{2} I_2^2 \frac{d L_2}{d x} \tag{56}$$

where I_1 and I_2, L_1 and L_2 are the respective currents and inductance coefficients of the two circuits; M, the mutual inductance; f_x, the component of force in the direction of x, "one of the geometrical variables on which the form and relative position depend."

Quoting Maxwell, "If the motion of the system corresponding to the variation of x is such that each circuit moves as a rigid body, L_1 and L_2 will be independent of x and the equation will be reduced to the form,"

$$f_x = I_1 I_2 \frac{d M}{d x} \tag{57}$$

Although it is clear from the above statement and his original assumptions, that the electrical circuits are not considered to be in proximity to iron or other magnetic material, nevertheless the equation holds, as will appear later, for circuits which do enclose, or are near, iron provided there is no saturation.

If there is a single circuit only, such as an electromagnet, all terms of (1) drop out except the first, thus reducing to the well-known expression,

$$f_x = \frac{1}{2} I^2 \frac{d L}{d x} \tag{58}$$

Thus for any circuit or pair of circuits in which the inductances are functions of shape or position only, Maxwell's equation applies.

Now there is another classical method of analysis according to which the force is obtained by integrating over the circuit member in question, the force on each current element, due to the magnetic density in which the element exists. In some cases this is more convenient to apply than the foregoing equations. It depends, of course, upon the nature of the problem. An excellent example of the application of the latter method is Dwight's[4] work regarding the electromagnetic force on switches.

Other authors, as listed in the bibliography, have also treated special cases, and in one or two of these, where saturation is considered, an additional step of fundamental nature has been taken. In 1911, Steinmetz[5] treated the special cases of electromagnets and transformers in accordance with existing theory, but in addition, considered the case of a single-circuit electromagnet containing iron and involving saturation. While his results were not carried further than the detailed expression of the *energy* relations which obtain during a change in position[6], this nevertheless consti-

6. This case is reviewed by Rudolph Richter in his *Elektrische Maschinen*, in which the equations are interpreted graphically.

tuted the initial step toward the derivation of a general equation for *force* of a single circuit.

Scope of Paper

Thus, the development to the present appears to include the solution of the cases of one and two circuits involving inductances which are not functions of the current, and of the case of a single circuit involving saturation, to the extent of the mathematical expressions for the various terms in the energy equation. It is the purpose here to give the general equation for a system of n circuits which may contain iron, either saturated or not, but assumed to have no hysteresis,

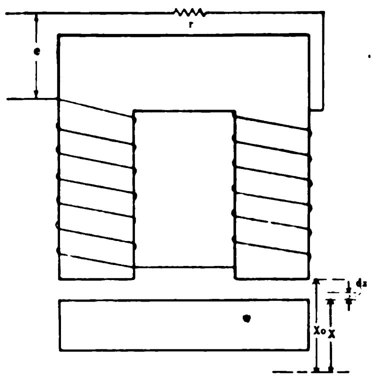

Fig. 1

and thus having inductances which are functions of both position and current; and in a subsequent paper in the near future, to apply the results to the case of mechanical forces in synchronous machines under short-circuit condition.

Two cases will be taken up in order; single circuit, and n circuits.

Single Circuit

The magnet in Fig. 1 is assumed to be excited to a point a on the saturation curve Fig. 2.

Let

ω = magnetic linkages $\times 10^{-8} = L\, i$

Ω = value of ω at which the force is to be determined; viz., $\Omega = L\, I$

L = inductance in henrys, defined as *linkages-per-ampere* $\times 10^{-8}$, and is a function of the current.

i = current in amperes.

I = value of i at which force is to be determined.

f_x = mechanical force exerted *on* the armature *by* the magnetic field, in the direction of x.

x = distance in cm. from arbitrary reference.

Although the electromagnet in Fig. 1 is a special case involving, as a result of symmetry, only one space coordinate, the general case is fully treated in Appendix A, equations (**5**) and (**6**).

Applying the principle of *virtual displacement* to the system in Fig. 1, let there be a displacement $d\,x$ of the armature, thus allowing the force f_x to do work. Then, referring to Fig. 2, the curve $o\,a$ corresponds to position x; curve $o\,b$, to position $x + d\,x$:

(a) Energy increment from electrical source during the position change $d\,x$ (I and Ω being variable during the change) $= I\, d\,\Omega$ = area $a\,b\,c\,d$, where $d\,\Omega$ is the increment due to the change $d\,x$.

(b) Total energy storage at position x and current $I = \int_0^\Omega i\, d\,\omega$ = area $o\,a\,d$ where $d\,\omega$ is the increment in ω, due to increment in current at constant x.

By conservation of energy, the increment in energy received from the electrical source during the change $d\,x$ must equal the sum of the mechanical work plus increment in stored magnetic energy. Thus,

$$I\, d\,\Omega = f_x\, d\,x + d \int_0^\Omega i\, d\,\omega$$

from which, by equations in Appendix A,

$$f_x\, d\,x = -\int_0^\Omega \frac{\partial i}{\partial x}\, d\,x\, d\,\omega \qquad \text{joules} \qquad (\mathbf{59})$$

In Fig. 2,

$$\frac{\partial i}{\partial x}\, d\,x = h$$

Thus,

(c) Mechanical work $= f_x\, d\,x = o\,a\,b'$

In equation (**59**), $d\,x$ is a constant in the integration. Hence

$$f_x = -\int_0^\Omega \frac{\partial i}{\partial x}\, d\,\omega \qquad \text{joules/cm.} \qquad (\mathbf{60})$$

which is the same as equation (**5**), Appendix A. Or,

$$f_x = -\,22.5 \int_0^\Omega \frac{\partial i}{\partial x}\, d\,\omega \qquad \text{lb.} \qquad (\mathbf{60a})$$

This is the *general equation* for force by a single

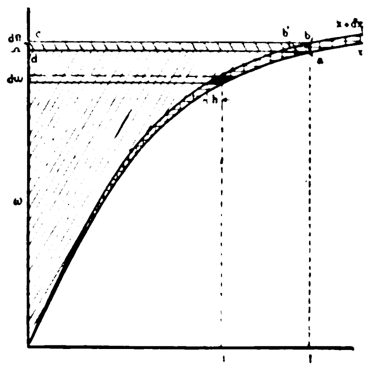

Fig. 2

circuit in which the inductance is a function of both position and magnetic flux, and is therefore applicable to electromagnets involving saturation.

Equation (**60**) is applied as follows:

Let,

$$i = f\,(\omega, x)$$

With ω as parameter, plot

$$i = F(x)$$

as in Fig. 3.[7] From this, plot

$$\frac{\partial i}{\partial x} = \varphi(\omega)$$

corresponding to X, as in Fig. 4. Then by equation (60), the force corresponding to the position X, current I, and linkages Ω, is the shaded area in Fig. 4.

Special Case. An interesting and important simplification is made possible by an assumption which will apply approximately to many actual cases. In Fig. 3, if no saturation exists, and neglecting the magnetic reluctance of the iron.

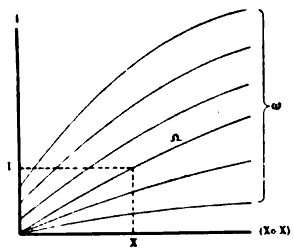

FIG. 3

$$i = 0 \text{ at } x = x_0$$

that is, when the air-gap $(x_0 - x) = 0$, since obviously no current would be required for zero reluctance. However, at values of ω which involve saturation, i has a definite value when the air-gap $(x_0 - x) = 0$, namely, the value required to sustain the magnetic flux in the saturated iron. But if, as in Fig. 3, the change in x is made at constant flux linkages, that is at approximately constant magnetic flux, the magnetic reluctance of the iron path should remain unchanged. Under this assumption *there is no change in that component of current which sustains the flux in the iron.* Thus the change in current due to such a change in x would be due wholly to the change in reluctance of the air path. This increment is indicated by h in Fig. 2, and corresponds to a change from x to $x + dx$, at a constant value of ω.[8]

These relations will now be written into equation (60).

By definition,

$$i = \frac{\omega}{L} \text{ amperes} \qquad (61)$$

and

$$L = \frac{N^2}{\mathcal{R}} \text{ henrys} \qquad (62)$$

where

$$N = \text{number of series turns.}$$

$$\mathcal{R} = \mathcal{R}_a + \mathcal{R}_i \text{ turns}^2/\text{henry} \qquad (63)$$

$\mathcal{R}$ = magnetic reluctance coefficient, which is made up of $\mathcal{R}_0$, applying to the air portion of the magnetic circuit; $\mathcal{R}_i$, to the iron portion.

Substituting (62) and (63) in (61) and differentiating partially with respect to x, taking ω constant,

$$\frac{\partial i}{\partial x} = \frac{\omega}{N^2}\frac{\partial}{\partial x}(\mathcal{R}_0 + \mathcal{R}_i)$$

But under the assumption,

$$\frac{\partial \mathcal{R}_i}{\partial x} = 0$$

Hence,

$$\frac{\partial i}{\partial x} = \omega \frac{\partial}{\partial x}\left(\frac{\mathcal{R}_0}{N^2}\right)$$

$$= \omega \frac{\partial}{\partial x}\left(\frac{1}{L_0}\right)$$

Thus,

$$\frac{\partial i}{\partial x} = -\frac{\omega}{L_0^2}\frac{\partial L_0}{\partial x} \text{ amperes/cm}$$ [redacted] (64)

Substituting (64) in (60),

$$f_x = \int_0^{\Omega} \frac{1}{L_0^2}\frac{\partial L_0}{\partial x}\,\omega\, d\omega$$

Making the assumption that in this integration

$$L_0 \text{ and } \frac{\partial L_0}{\partial x}$$

are not functions of ω, they may then be placed outside of the integral sign[9]. The integral then becomes

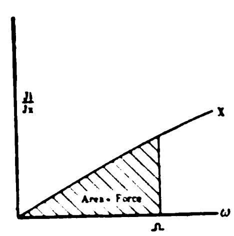

FIG. 4

$$f = \frac{1}{2}\frac{\Omega^2}{L_0^2}\frac{\partial L_0}{\partial x} \text{ joules/cm} \qquad (65)$$

Thus, for those cases where the above assumptions approximately hold, the force is expressed in the following known and convenient terms: the actual magnetic

7. It is more convenient in the particular case of Fig. 1 to plot i as $F(x_0 - x)$ instead of $F(x)$.

8. In calculating force, it makes no difference in the value whether it is assumed that the change dx is made at constant linkages, as above, or at constant current. Referring to Fig. 2, the difference in mechanical work is represented by the second order area $a\,b\,b'$, which vanishes in the limit.

9. Thus, equation (63) holds only in so far as R_0 and the ratio $\frac{d\,\mathcal{R}_0}{d\,x}$ are independent of ω.

linkages corresponding to the existing current I and position X; the constant (with respect to ω) inductance L_0 corresponding to the straight part of the (ω, i) curve, Fig. 1; and the rate at which that inductance changes with respect to x.

Equation (**65**) can be written in the following form:

$$f = \frac{1}{2} I_f^2 \frac{\partial L_0}{\partial x} \text{ joules/cm.} \quad (66)$$

where I_f is the fictitious current,

$$I_f = \frac{\Omega}{L_0} = I \frac{L}{L_0} \text{ amperes} \quad (67)$$

thus smaller than the actual current I by the ratio of the inductance at the actual current, to the inductance corresponding to no saturation.

Or in still another form,

$$f = \frac{1}{2}\left(\frac{L}{L_0}\right)^2 I^2 \frac{\partial L_0}{\partial x} \text{ joules/cm.} \quad (68)$$

Or, in pounds

$$f = 11.25\left(\frac{L}{L_0}\right)^2 I^2 \frac{\partial L_0}{\partial x} \text{ lb.} \quad (66a)$$

Thus if,

$$L = L_0$$

that is, with no saturation,

$$f = \frac{1}{2} I^2 \frac{\partial L_0}{\partial x} \quad (69)$$

This is the well-known expression for a single circuit with no saturation. Comparison of (**68**) and (**69**) shows that saturation decreases the force, at the same current I, by the ratio

$$\left(\frac{L}{L_0}\right)^2$$

It is interesting to note that under the assumptions contained in equation (**65**), equation (**60**) also reduces to the familiar form

$$f_x = \frac{\beta^2 A}{8\pi} 10^{-7} \qquad \text{joules/cm.}$$

when applied to the special case of a magnet with relatively small uniform air-gap.

Let the total magnetomotive force for the magnetic circuit corresponding to the linkages ω be,

$$N i = F(\omega) + \frac{\omega (x_0 - x) 10^8}{0.4 \pi N A}$$

where A is the cross section in sq. cm., β is the magnetic density in lines per sq. cm. of the air path, and $F(\omega)$ represents the saturation curve of the iron alone. Thus, differentiating partially with respect to x,

$$\frac{\partial i}{\partial x} = -\frac{\omega 10^8}{0.4 \pi N^2 A}$$

Substituting this in (**60**) and integrating,

$$f_x = \frac{10^8}{0.8 \pi A}\left(\frac{\Omega}{N}\right)^2 = \frac{\beta^2 A}{8\pi} 10^{-7} \text{ joules/cm.}$$

n CIRCUITS

General Case. From Appendix B, the general equation for f_x for the case of n circuits is given in the following two forms:

$$f_x = -\sum_1^n \int_0^{\Omega_u} \frac{\partial i_u}{\partial x} d\,\omega_u \qquad \text{joules/cm.} \quad (9)$$

and

$$f_x = \sum_1^n \int_0^{I_u} \frac{\partial \omega_u}{\partial x} d\,i_u \qquad \text{joules/cm.} \quad (11)$$

The application of (**9**) may be illustrated as follows: As discussed in Appendix B, any functional relation between the currents, or between the linkages may be assumed during the integration indicated, provided that relation brings all currents to their given values, which are the limits of the integrals. Thus, assume the currents are brought up, proportional to each other, the proportionality constants being the ratios of the final values I_1, I_2, I_3, etc. Then, for any value of i_u, all other currents and values of ω, at a given value of x, are fixed. Thus, for each circuit, following the same procedure as indicated for the case of a single circuit, equation (**60**), Figs. 3 and 4,

$$i_u = f_u(\omega_u, x)$$

with ω_u as parameter, plot

$$i_u = F_u(x)$$

for each circuit. From these, plot the corresponding curves,

$$\frac{\partial i_u}{\partial x} = \phi_u(\omega)$$

corresponding to the particular value of x. Then the force is the sum of the areas corresponding to that in Fig. 4.

A similar procedure may be followed in the application of the other form, equation (**11**).

Special Case: Inductance Independent of Current. From Appendix C, one of the two equations derived for f_x, under the assumption that L's and M's are independent of the current is

$$f_x = \sum_1^n{}_u \sum_1^n{}_v \frac{I_u I_v}{2} \frac{d M_{uv}}{d x} \text{ joules/cm.} \quad (21)$$

where M_{uv} = mutual inductance in henrys of circuit v upon circuit u.[10]

Thus for $n = 3$, for illustration,

$$f_x = \frac{1}{2} I_1^2 \frac{d L_1}{d x} + \frac{1}{2} I_2^2 \frac{d L_2}{d x} + \frac{1}{2} I_3^2 \frac{d L_3}{d x}$$

10. When $u = v$, self induction is indicated. Thus $M_{11} = L_1$, $M_{22} = L_2$, etc.

$$+ I_1 I_2 \frac{d M_{12}}{d x} + I_1 I_3 \frac{d M_{13}}{d x} + I_2 I_3 \frac{d M_{23}}{d x}$$

$$\text{joules/cm.} \qquad (70)$$

For two circuits only, equation (70) reduces to Maxwell's equation, as given in (56).

The other equation for f_x for this case is

$$f_x = - \sum_1^n {}_u \sum_1^n {}_v \frac{\Omega_u \Omega_v}{2} \frac{d K_{uv}}{d x} \text{ joules/cm.} \qquad (26)$$

where K_{uv} is a "coefficient of magnetization," discussed in Appendix C, and defined in general by

$$I_u = \sum_1^n {}_v K_{uv} \Omega_v \text{ amperes} \qquad (24)$$

Approximation. Making the same simplifying assumptions as contained in equations (64) and (65), discussed under "Single Circuit," saturation may be approximately taken into account in the equations.

As explained in Appendix *D*, the above mentioned assumptions reduce equation (9) to the form,

$$f_x = - \sum_1^n {}_u \sum_1^n {}_v \frac{\Omega_u \Omega_v}{2} \frac{d K_{uv}}{d x} \qquad (32)$$

where Ω_u and Ω_v are the linkages of circuits u and v corresponding to the actual currents I_1, I_2, I_3, etc., under the existing condition of partial saturation of the iron paths of the magnetic circuit; and where K_{uv} is the coefficient of magnetization, discussed in Appendix C, applying to the *non-saturated* condition. In other words, equation (32) is of exactly the same form—indeed, the same equation—as (26), which applies to the *non-saturated* case. Thus, under the assumptions, different expressions for the force are encountered for the saturated and non-saturated conditions, only when the force is expressed in terms of *currents*; but the same equation is obtained for either case when it is expressed in terms of linkages.

In Appendix E, expressions have been worked out for K_{uv} for 1, 2, 3, and 4 circuits in terms of the self and mutual inductances without saturation, namely L_u and M_{ur}.

To illustrate the application of (32), take the case of a single circuit. Here,

$$K_{uv} = K_{11} = \frac{1}{L_0}$$

Then

$$f_x = \frac{\Omega_1^2}{2} \left(\frac{d}{d x} \frac{1}{L_0} \right)$$

or

$$f_x = - \frac{1}{2} \frac{\Omega_1^2}{L_0} \frac{d L_0}{d x}$$

It will be noted that this is the same as equation (65). Thus, under the assumption, if the values of $\Omega_1, \Omega_2, \Omega_3$, etc., are known in any system involving saturated iron, the force is approximately determined by (32), using K_{uv} as given in Appendix E.

It is possible to express the force, in the case of n circuits, and under the above assumptions, as follows: Equations (21) and (26) express exactly the same result for the non-saturated case. But equation (32), which is the same as equation (26), gives the force for the saturated case. Therefore, equation (21) *will apply also to the saturated case, under the assumptions, provided such fictitious current values are used as will cause the actual existing values of* $\Omega_1, \Omega_2, \Omega_3$, etc.

Thus, knowing the values of Ω_1, Ω_2, etc., n simultaneous equations may be written for the n values of current, in terms of L's and M's as follows:

$$\left.\begin{aligned} \Omega_1 &= I_1 L_1 + M_{12} I_2 + M_{13} I_3 + \ldots \\ \Omega_2 &= I_2 L_2 + M_{21} I + M_{23} I_3 + \ldots \\ \Omega_3 &= I_3 L_3 + M_{31} I_1 + M_{32} I_2 + \ldots \end{aligned}\right\} \frac{\text{Linkages}}{10^8} \qquad (71)$$

The force is then obtained by substituting in equation (21) the fictitious values of current I_1, I_2, I_3, etc., as found by solving equation (71). The solution for these currents may be readily obtained by substituting in

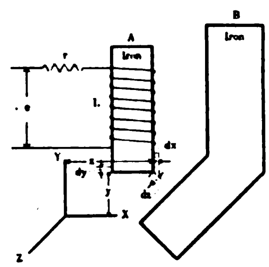

Fig. 5

equation (24) the known values of linkages Ω_v and the values of K_{uv} as determined by the equations given in Appendix E.

The authors gratefully acknowledge the valuable suggestions and encouragement of V. Karapetoff, and the assistance of J. M. Bryant, D. S. Snell and R. M. Ryan.

PHOTOELECTRIC CELL SPOTS FOREST FIRES

A new use has been found for the photoelectric cell, that delicate electrical device that has made sending pictures by wire possible. This unusual application is the detecting of forest fires. Strung between two points in a mountainous and heavily timbered region, a cable carries a car upon which is mounted a powerful electric searchlight.

The car travels back and forth on this cable and the beam of the searchlight is constantly focused upon the photoelectric cell mounted upon the platform of the forest fire lookout tower. Nothing happens until the beam of the searchlight has to pass through smoke arising from a forest fire. Then the photoelectric cell, because the beam of light is dimmed, comes into action and sounds an alarm and the forest rangers are "turned out" to fight the fire.

Theory of Absorption in Solid Dielectrics

VLADIMIR KARAPETOFF[1]

Fellow, A. I. E. E.

Synopsis.—*Most solid dielectrics are imperfect in the sense that when a constant d-c. voltage is suddenly applied, a displacement of electricity first takes place almost instantly to a certain value, and then continues to increase asymptotically towards an ultimate magnitude. Accordingly, an initial electric charge and a greater final charge may be distinguished, with the corresponding values of initial and final permittivities. The purpose of the present investigation is to establish certain general properties of the function which expresses the increase in the initial electric displacement with the time. The initial and the final leakage conductivities of the material are also taken into consideration.*

An assumption is made that the law of relaxation of electric displacement in the individual particles of the dielectric is a simple exponential function of time, but that the exponent varies from particle to particle. In some "non-viscous" particles the final displacement takes place instantly, in some others it occurs infinitely slowly, while for a great majority of the particles the relaxation proceeds at various finite rates. A "distribution function" for the numbers of different particles is introduced and the general conditions which this function must satisfy are established.

The results are then applied to a particular form of distribution function which has a large enough number of parameters for representing experimental data on a given dielectric with sufficient accuracy. Integrations are carried out for the cases of direct and sinusoidal applied voltages. With direct voltage, expressions are deduced for the permittivity and conductivity as functions of time. Since experimental curves of these two quantities can be obtained, a comparison with the theoretical formulas will permit a determination of the numerical values of the parameters in the assumed distribution function. With alternating voltages, the apparent permittivity and the apparent conductivity are expressed as functions of the frequency. Since experimental values of these quantities may be computed from measurements of capacitance and dielectric loss, another possibility is thus afforded for checking an assumed distribution function.

The ultimate aim of the theory (as now developed and as may be improved in the future) is to make it possible to correlate and to mutually check a vast amount of experimental data on absorption and on dielectric loss, and to enable one to predict these quantities within the range of voltages and frequencies for which no test figures are available.

* * * * *

WHEN a constant continuous voltage is suddenly applied to an imperfect solid dielectric, a phenomenon, shown in Fig. 1, takes place. Let the piece of dielectric be in the form of a slab of thickness a and let the applied voltage be E. Then the *voltage gradient* in the material is

$$G = E/a \tag{1}$$

By assumption, this gradient remains constant, as shown by a horizontal line in Fig. 1. Let the cross-section of the slab in the plane normal to the lines of force be A, and let the total quantity of electricity displaced through the slab be Q. Then the density of displacement, or the *dielectric flux density*, is

$$D = Q/A \tag{2}$$

Experiment shows that D does not reach its final value D_f at once, but continues to increase from an initial value $D_0 = O\,a$ to $D_f = O\,b$ over an appreciable interval of time. Accordingly, a charging current is produced,

$$i = d\,Q/d\,t \tag{3}$$

which continues to flow into the dielectric. Since D refers to unit cross-section of the slab, we shall also introduce the *current density*

$$u = d\,D/d\,t \tag{4}$$

instead of the total current i. At $t = o$, the density u is equal to zero; then it rapidly rises to a value $O\,c$ determined by eq. (4), and begins to decrease. We are not interested in the part $O\,d$ of the curve, since it is determined by the inductance of the circuit, and we shall assume that point d is reached practically at $t = o$. If the applied voltage is of very high frequency instead of being continuous, the inductance of the circuit, including the magnetic field in the dielectric itself, may become a factor of appreciable magnitude. If the conductivity of the dielectric is zero, the current finally becomes equal to zero. Otherwise, the current density asymptotically reaches a steady small value, $u_f = h\,f$.

The above described phenomenon is known as *dielectric absorption*, and is present to some degree in most solid dielectrics, especially in those whose molecular structure is non-homogeneous or complicated. Absorption affects both the charge and the discharge of a condenser, causes the true capacitance to be a somewhat indefinite quantity and, with alternating voltages, causes dielectric loss.

A study of absorption is of interest not only from the point of view of the nature of dielectric phenomena, but also in application to charge and discharge of condensers and to dielectric loss.

In view of our meager knowledge of the atomic structure and electronic forces in solids, the time for a rational theory of dielectric absorption has not arrived. It is therefore necessary to establish a semi-empirical theory, with functions chosen by trial to represent the general character of the curves shown in Fig. 1 and with constants determined by tests. Nevertheless, such a theory is useful in permitting us to interpret some observed phenomena and to predict numerical values not actually measured. The theory given below is a further extension of that given by K. W. Wagner.[2] A

1. Professor of Electrical Engineering, Cornell University, Ithaca, N. Y.

somewhat different approach to the problem, based on the idea of "stratified" dielectrics, was given by Maxwell[3] and recently further developed by Grünewald.[4]

The character of the curves shown in Fig. 1 suggests the presence of three kinds of paths or "fibers" between the electrodes (Fig. 2); namely, (a) portions of a perfect dielectric, in which an electric displacement faithfully

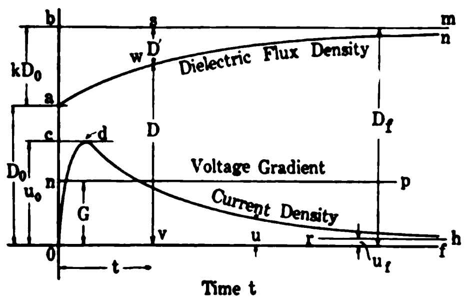

FIG. 1—VARIATIONS IN THE DIELECTRIC FLUX AND CURRENT DENSITY WITH THE TIME

When a constant d-c. voltage is applied suddenly

and instantly follows the applied voltage; (b) portions of an imperfect dielectric in which the final orientation of molecular charges requires some time and is opposed by some kind of viscous reactions; and (c) conducting paths. Of course, all these portions are of irregular shapes and intermingled in series and in parallel, the three distinct fibers being shown merely for the sake of convenience. Such a dielectric would behave as indicated in Fig. 1.

A mechanical analog to the behavior of an imperfect dielectric is shown in Fig. 3. $A\,B$ is a stationary plate and $C\,D$ is an identical plate connected to it by two springs, S_1 and S_2. A vessel V, filled with viscous liquid, is attached to $A\,B$. A plate q, supported by the

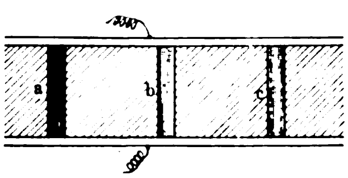

FIG. 2—THREE ASSUMED KINDS OF FIBERS OR PARTICLES IN AN IMPERFECT DIELECTRIC

Viz., a. perfectly elastic, b. viscously elastic, c. conducting

spring C, is immersed in the liquid. Two weights, G_1 and G_2, rest on supports h_1 and h_2, and are attached to $C\,D$ by strings over the stationary pulleys P_1 and P_2. The lower ends of the springs S_1 and S_2 are attached to the stems K_1 and K_2 fitted into the board $A\,B$ with considerable friction.

Assume the apparatus to be initially in equilibrium with no tension in the springs and with the weights resting on their supports. Now let h_1 and h_2 be suddenly withdrawn, causing the weights to pull $C\,D$ upward and to stretch the springs S_1, S_2 and C. Consider the stems K_1 and K_2 to be so tight as not to move, and assume the motion of q to be negligible at first, due to the viscosity of the liquid. The tension is then initially taken up by the three springs. As the pull continues, the plate q moves upward, relieving the tension of C so that ultimately the whole tension is taken up by S_1 and S_2 only. This subsequent increase in the tension and displacement of the springs S_1 and S_2 illustrates the effect of absorption. Let now the supports K_1 and K_2 be slightly yielding. Then the motion of $C\,D$ will never stop, thus giving a picture of a conduction current.

If the stress be suddenly changed before the final stage has been reached, the additional stress put on C depends upon the position of the plate q. Thus, the amount of absorption depends upon the previous history of the sample.

If the weights be suddenly removed (corresponding to

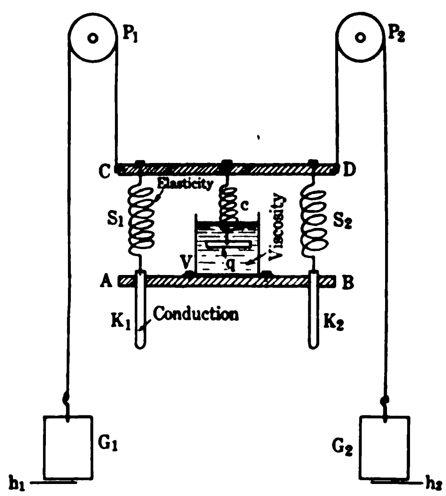

FIG. 3—A MECHANICAL ANALOG OF AN IMPERFECT SOLID DIELECTRIC

a short-circuit), there will be an instant position of equilibrium at which the tension of the springs S_1 and S_2 will balance the compression of the spring C. Then, gradually, the bar $C\,D$ will go down to a final position of equilibrium. If, however, the short-circuit be removed before the final position has been reached, and the bar $C\,D$ locked (to correspond to an open circuit) a readjustment of stresses will take place, with a residual charge. Thus, later, upon releasing $C\,D$, another movement will take place without an application of the weights.

The influence of temperature can be taken into account by changing the viscosity of the liquid in V; for instance, by heating it.

Of course, this analog cannot be followed in detail, but it may facilitate an understanding of the general nature of phenomena taking place in an imperfect dielectric. The writer has also designed a kinematic

3. Electricity and Magnetism, Vol. 1, p. 452.
4. Archiv für Elektrotechnik, 1923, Vol. 12, p. 96.

linkage with a spring and a dashpot, to illustrate the ideas discussed in the above mentioned article by Grünewald. See also Maxwell's model, *ibid.*, p. 462.

2. The Fundamental Equations

The phenomenon shown in Fig. 1 is primarily determined by the ratio of D_0 to D_f and by the shape of the curve $a\,n$. Let the final displacement be $1 + k$ times the original displacement. Then, in Fig. 1, $a\,b = k\,D_0$, and the *absorption coefficient* k may be defined by the equation

$$k = (D_f - D_0)/D_0 \quad (5)$$

For a perfect dielectric, $k = 0$; the greater k, the more absorption manifested by the material.

Assume $a\,b = 1$ and let the equation of the curve $a\,n$, referred to the axis $b\,m$, be $\phi\,(t)$. The function $\phi\,(t)$ may be called the *relaxation function*, as it characterizes the rate at which the absorbed charge is being released with the time. Let κ_0 be the *initial permittivity* of the material; that is, the permittivity that would be obtained from a ballistic test at the first instant of voltage application. In other words, let

$$D_0 = \kappa_0\,G \quad (6)$$

and

$$D_f = (1 + k)\,\kappa_0\,G \quad (7)$$

At any instant, t, the *deficiency* $D' = w\,s$ between the final displacement D_f and the actual displacement D is

$$D' = k\,D_0\,\phi\,(t) = k\,\kappa_0\,G\,\phi\,(t) \quad (8)$$

Hence

$$D = D_f - D' = \kappa_0\,G\,[(1 + k) - k\,\phi\,(t)] \quad (9)$$

According to eq. (4),

$$u = -\,\kappa_0\,\kappa\,G\,d\,\phi\,(t)/d\,t \quad (10)$$

In these equations, the function $\phi\,(t)$ is as yet arbitrary, except that it must correspond to a curve the general shape of which is that of the curve $a\,n$, and must satisfy the terminal conditions

$$\phi\,(o) = 1 \text{ and } \phi\,(\infty) = 0 \quad (11)$$

The factor k may be expressed through the *final permittivity* of the material, κ_f, as follows: After the sample has been subjected to a constant d-c. voltage for a long time, we have, by analogy with Equation (6):

$$D_f = \kappa_f\,G \quad (12)$$

so that

$$(D_f - D_0)/D_0 = (\kappa_f - \kappa_0)/\kappa_0 \quad (13)$$

Comparing this expression with equation (5), it will be seen that

$$k = (\kappa_f - \kappa_0)/\kappa_0 \quad (14)$$

and

$$\kappa_0\,k = \Delta\,\kappa = \kappa_f - \kappa_0 \quad (14a)$$

where $\Delta\,\kappa$ is the apparent increase in the permittivity, due to absorption.

The next step is to generalize Equations (9) and (10) for the case when the applied voltage is not constant but varies with the time in a prescribed manner. Let us begin with the simplest case when a constant stress G_1 (Fig. 4) is applied from $t = 0$ to $t = \tau$, and is then increased by an amount G_2. The new stress, $G_1 + G_2$, may be assumed to last indefinitely. The flux density curve, $a\,w$, is similar to that in Fig. 1 as long as G_1 is acting alone. At the instant of application of G_2 the flux density is suddenly increased by an amount $w\,w'$ and then continues to increase asymptotically towards a new limit $b'\,m'$.

It is impossible to deduce, theoretically, the relationship between the displacement $p\,w$, existing at the instant τ and the resultant displacement $p\,w'$ an instant later, due to a suddenly increased voltage. We shall therefore make the simplest assumption; namely, that the added voltage G_2 produces its own displacement curve, just as if G_1 did not exist, and that the displacements due to G_1 and G_2 are simply added together.

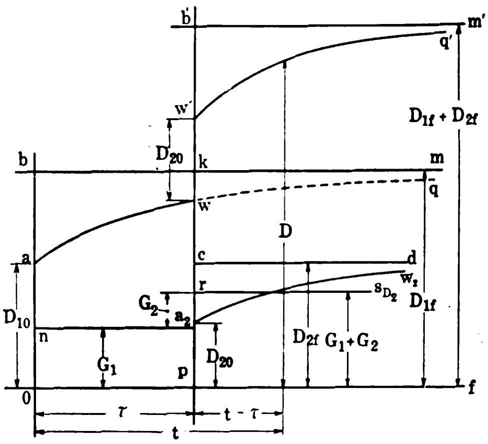

FIG. 4—VARIATIONS IN THE DIELECTRIC FLUX DENSITY
When a constant d-c. voltage is applied in two steps

According to this principle of superposition (due to Hopkinson), the curve $a\,w$ continues in the range $w\,q$ as if G_2 did not exist, while the stress G_2 causes a new curve, $a_2\,w_2$, the initial ordinate of which is $D_{2o} = \kappa_0\,G_2$, and the final value is $D_{2f} = (1 + k)\,\kappa_0\,G_2$; equations (6) and (7). The ordinates of the curve $a_2\,w_2$ added to those of $w\,q$ will give the curve of resultant displacement, $w'\,q'$. This is a mathematical hypothesis, justified only by the possibility of deducing on this basis a set of formulas which can be made to fit observed curves to a sufficient degree of accuracy. From a physical point of view, we know that the a fibers (Fig. 2) satisfy the law of superposition because, in a perfect condenser, the charge is strictly proportional to the voltage. The c fibers also satisfy the law of superposition in that a current is proportional to the applied voltage. Therefore, it is only necessary to grant that the viscous or b fibers also obey this law. In a viscous fluid, at low velocities, the velocity is proportional to the applied force, so that the superposition hypothesis seems reasonable for these fibers as well.

Thus, for any instant $t > \tau$, we may write

$$D = \kappa_0 (1 + k) (G_1 + G_2) - \kappa_0 k [G_1 \phi (t) + G_2 \phi (t - \tau)] \quad (15)$$

Let now the total stress G_t, which exists at the instant t, be gradually built up in small increments ΔG_τ, each of which is applied at a different instant τ. Generalizing equation (15), we get

$$D = \kappa_0 (1 + k) G_t - \Delta \kappa \Sigma \Delta G_\tau \phi (t - \tau) \quad (16)$$

where

$$\Sigma \Delta G_\tau = G_t \quad (17)$$

and $\Delta \kappa$ is used in place of $\kappa_0 k$, according to equation (**14a**).

In the limit, let the applied voltage vary continuously; then, equation (16) becomes

$$D = \kappa_0 (1 + k) G_t - \Delta \kappa \int_{t_0}^{t} \left(\frac{d G_\tau}{d \tau} \right) \phi (t - \tau) d \tau \quad (18)$$

where t_0 is the instant at which the voltage is first applied to the sample. In changing from equation (16) to equation (18), ΔG_τ is divided and multiplied by $\Delta \tau$, and, in the limit, Δ is replaced by d.

In equation (18), ϕ is an assumed function, while G_τ is the impressed stress. It is more convenient to have a derivative of ϕ than of G_τ. Integrating in parts, we get

$$\int_{t_0}^{t} \left(\frac{d G_\tau}{d \tau} \right) \phi (t - \tau) d \tau = G_\tau \phi (t - \tau) \Big|_{t_0}^{t} - \int_{t_0}^{t} G_\tau d_\tau \phi (t - \tau) \quad (19)$$

But

$$G_\tau \phi (t - \tau) \Big|_{t_0}^{t} = G_t \phi (o) - G_{t0} \phi (t - t_0) \quad (20)$$

According to equation (11), $\phi (0) = 1$; moreover, $G_{t_0} = 0$, since, by assumption, t_0 is the instant at which the voltage begins to be applied. Hence, the value of the right-hand side of equation (20) is simply G_t. Using this value in equation (19) and substituting the value of the integral in equation (18), gives

$$D = \kappa_0 G_t + \Delta \kappa \int_{t_0}^{t} G_\tau d_\tau \phi (t - \tau) \quad (21)$$

Using this expression for D in equation (4), we get the following expression for the current density:

$$u = \kappa_0 \left(\frac{d G_t}{d t} \right) + \Delta \kappa \int_{t_0}^{t} G_\tau \left[\frac{d^2 \phi (t - \tau)}{d t \, d \tau} \right] d \tau + \Delta \kappa G_t \left[\frac{d \phi (t - \tau)}{d \tau} \right] \tau = t \quad (22)$$

When taking a total derivative of the definite integral in equation (21), with respect to t, two terms are obtained; viz., one assuming t to be a parameter under the sign of integral, and the other assuming t to be a variable upper limit. Equations (21) and (22) are the fundamental equations in the theory under consideration. In so far as no particular form has been ascribed to the function ϕ, these equations are perfectly general. The next step is to specify the function ϕ in accordance with the observed behavior of solid dielectrics.

3. An Exponential Law of Relaxation

In Fig. 1, the simplest assumption which can be made regarding the shape of the curve, $a\,n$, is that the "deficiency" $w\,s$ is an exponential function of time; that is

$$\phi (t) = \epsilon^{-\alpha t} \quad (23)$$

where α is a *relaxation factor* which characterizes the sample under consideration. Equation (23) proposed by Pellat[5], satisfactorily represents the general shape of the curve $a\,n$ and also satisfies equations (11). On the other hand, substances which show considerable absorption are usually too complicated to be characterized by a single parameter α. Therefore, von Schweidler proposed a generalization of the foregoing formula to

$$\phi (t) = (\Sigma N \epsilon^{-\alpha t}) / \Sigma N \quad . \quad (24)$$

Here the material is supposed to be heterogeneous and to consist of N_1 particles of constant α_1, N_2 particles of constant α_2, etc.

Wagner has further extended this idea and proposed for the relaxation function an expression of the form

$$\phi (t) = \int_0^\infty F (\alpha) \epsilon^{-\alpha t} d \alpha \quad (25)$$

the integration being with respect to α, and not t. His idea was that a piece of heterogeneous dielectric may have some particles with a relaxation constant $\alpha = 0$ (perfect dielectric, no relaxation) and others with $\alpha = \infty$ (conducting particles, instant relaxation). For most particles, α lies between zero and infinity, and the number of particles which have a definite value of α is a function of α. In other words, for a fairly uniform material, α ranges within rather narrow limits for a great majority of particles, and there are comparatively few particles with very large or small values of α, due to admixtures and impurities. A specific form of $F (\alpha)$ will be considered in the next section. We shall first deduce some general expressions which hold true for any function of α. The function $F (\alpha)$ may be called the distribution function, because it shows the relative number of particles having different values of α.

From the physical significance of $F (\alpha)$, we judge that this function remains finite between $\alpha = 0$ and $\alpha = \infty$. Therefore the second equation (11) is satisfied. In order that the first equation (11) be satisfied, the function $F (\alpha)$ must satisfy the condition

$$\int_0^\infty F (\alpha) d \alpha = 1 \quad (26)$$

We shall now apply expression (25) to equations (21) and (22) and deduce some special cases.

General Case of Variable Voltage.

Equation (25) gives

$$\phi (t - \tau) = \int_0^\infty F (\alpha) \epsilon^{-\alpha(t - \tau)} d \alpha \quad (27)$$

5. For literature references see the above mentioned article by Wagner.

so that

$$d_\tau \phi(t-\tau) = \int_0^\infty \alpha F(\alpha)\, \epsilon^{-\alpha(t-\tau)}\, d\alpha\, d\tau \quad (28)$$

and

$$[d^2 \phi(t-\tau)/dt\, d\tau]\, d\tau = -\int_0^\infty \alpha^2 F(\alpha) \epsilon^{-\alpha(t-\tau)}\, d\alpha\, d\tau \quad (29)$$

Substituting expression (28) in equation (21), gives

$$D = \kappa_0 G_t + \Delta\kappa \int_{t_0}^{t} G_\tau\, d\tau \int_0^\infty \alpha F(\alpha)\, \epsilon^{-\alpha(t-\tau)}\, d\alpha \quad (30)$$

The integration with respect to time is independent of that with respect to α. Changing, therefore, the order of integration, the foregoing equation becomes

$$D = \kappa_0 G_t + \Delta\kappa \int_0^\infty \alpha F(\alpha)\, \epsilon^{-\alpha t} \left[\int_{t_0}^{t} G_\tau\, \epsilon^{\alpha\tau}\, d\tau \right] d\alpha \quad (31)$$

Substituting expressions (28) and (29) in equation (22), gives

$$u = \kappa_0 \frac{d G_t}{d t} - \Delta\kappa \int_{t_0}^{t} \int_0^\infty G_\tau\, \alpha^2 F(\alpha)\, \epsilon^{-\alpha(t-\tau)}\, d\alpha\, d\tau + \Delta\kappa G_t \int_0^\infty \alpha F(\alpha)\, d\alpha \quad (32)$$

Equation (32) may also be deduced directly from equation (31) by differentiation; see equation (4).

Continuous Constant Voltage. In this case, $G_t = G_\tau = G$; assume also $t_0 = 0$. We then have for the second integral in equation (31)

$$\int_{t_0}^{t} G_\tau\, \epsilon^{\alpha\tau}\, d\tau = G \int_0^t \epsilon^{\alpha\tau}\, d\tau = \left(\frac{G}{\alpha}\right)(\epsilon^{\alpha t} - 1) \quad (33)$$

Therefore, the first integral in equation (31) becomes

$$G \int_0^\infty F(\alpha)\, \epsilon^{-\alpha t} (\epsilon^{\alpha t} - 1)\, d\alpha = G \int_0^\infty F(\alpha)\, d\alpha - G \int_0^\infty F(\alpha)\, \epsilon^{-\alpha t}\, d\alpha \quad (34)$$

According to equation (26), the value of the first integral on the right hand side is 1. Substituting from equation (34) in equation (31) and dividing by G, gives

$$\kappa_t = \frac{D}{G} = (\kappa_0 + \Delta\kappa) - \Delta\kappa \int_0^\infty F(\alpha)\, \epsilon^{-\alpha t}\, d\alpha \quad (35)$$

Here κ_t may be considered to be the *apparent permittivity* of the sample at the instant t. When $t = 0$, $\kappa_t = \kappa_0$; when $t = \infty$, $\kappa_t = \kappa_0 + \Delta\kappa = \kappa_f$.

The current density u may be obtained directly by differentiating the right-hand side of equation (35) with respect to t, and multiplying the result by G. We then get

$$u = \Delta\kappa G \int_0^\infty \alpha F(\alpha)\, \epsilon^{-\alpha t}\, d\alpha \quad (36)$$

Let γ be the final conductivity of the sample, that is, the conductivity of the fibers c in Fig. 2. Then the *apparent conductivity* at the instant t is

$$\gamma_t = \frac{u}{G} + \gamma_f \quad (37)$$

The first term on the right-hand side corresponds to the displacement current and the second to the real conduction current. Substituting in equation (37) the value of u from equation (36), gives

$$\gamma_t = \Delta\kappa \int_0^\infty \alpha F(\alpha)\, \epsilon^{-\alpha t}\, d\alpha + \gamma_f \quad (38)$$

The initial conductivity, at $t = 0$, is

$$\gamma_0 = \Delta\kappa \int_0^\infty \alpha F(\alpha)\, d\alpha + \gamma_f \quad (39)$$

Thus the function $F(\alpha)$ must satisfy the condition

$$\int_0^\infty \alpha F(\alpha)\, d\alpha = \frac{\gamma_0 - \gamma_f}{\kappa_f - \kappa_0} \quad (40)$$

where the four quantities on the right-hand side characterize the material.

Alternating Voltage. For a sinusoidal applied voltage we can generally put

$$G_\tau = G_m\, \epsilon^{j\omega t} \quad (41)$$

More particularly, at the instant t,

$$G_t = G_m\, \epsilon^{j\omega t} \quad (41a)$$

where G_m is the amplitude of the stress and ω its frequency. It is convenient to put $t_0 = -\infty$ because then the transient term disappears. The second integral in equation (31) becomes

$$G_m \int_{-\infty}^{t} \epsilon^{(j\omega+\alpha)\tau}\, d\tau = \frac{G_m\, \epsilon^{(j\omega+\alpha)t}}{(j\omega + \alpha)} \quad (42)$$

so that, using in equation (31) the value of G_t from equation (41a), we get

$$D = G_m\, \epsilon^{j\omega t} \left[\kappa_0 + \Delta\kappa \int_0^\infty \frac{\alpha F(\alpha)}{(j\omega + \alpha)}\, d\alpha \right] \quad (43)$$

Multiplying the numerator and the denominator of this equation by $(\alpha - j\omega)$, and separating the real from the imaginary part, we get

$$D = G_m\, \epsilon^{j\omega t} \left[\kappa_0 + \Delta\kappa \int_0^\infty \frac{\alpha^2 F(\alpha)\, d\alpha}{(\alpha^2 + \omega^2)} - j\omega\Delta\kappa \int_0^\infty \frac{\alpha F(\alpha)\, d\alpha}{(\alpha^2 + \omega^2)} \right] \quad (44)$$

The sample under consideration may be thought of as a combination of an ideal capacitance, C, in parallel with a conductance, g. The latter is *not* the conductance due to leakage, but the apparent conductance caused by absorption. For such a combination, the current

$$I = E\, \epsilon^{j\omega t} (j\omega C + g) \quad (45)$$

Consequently, the charge varies according to the law

$$Q = E\, \epsilon^{j\omega t} \left(C - \frac{jg}{\omega} \right) \quad (46)$$

because a derivative of equation (46) with respect to t gives equation (45). Equation (44) corresponds to equation (46) for unit volume of the dielectric. Therefore, comparing the two equations term by term, we find that

$$\kappa_\omega = \kappa_0 + \Delta\,\kappa \int_0^\infty \frac{\alpha^2 F(\alpha)\, d\alpha}{(\alpha^2 + \omega^2)} \qquad (47)$$

$$\gamma_\omega = \Delta\,\kappa\,\omega^2 \int_0^\infty \frac{\alpha F(\alpha)\, d\alpha}{(\alpha^2 + \omega^2)} + \gamma_f \qquad (48)$$

In the latter expression, the term γ_f is added to account for the actual leakage conductivity (fibers c in Fig. 2). Thus, with alternating voltages, a dielectric with absorption shows a permittivity and a conductivity both of which are functions of the frequency. Equations (47) and (48) show that the relationship between κ_ω, γ_ω, and ω is quite involved. Nevertheless, it is this relationship that should permit to compare the theory with observed results.

Differentiating equation (44), or directly on the basis of equation (45), we may write for the current density u:

$$u = G_m\, \epsilon^{j\omega t}\, (j\,\omega\,\kappa_\omega + \gamma_\omega) \qquad (49)$$

where κ_ω and γ_ω are determined by equations (47) and (48).

In equation (47), κ_0, by definition, is the initial or instant permittivity; therefore, it is the permittivity which the dielectric should show at an infinite frequency. In fact, by putting $\omega = \infty$, equation (47) gives

$$\kappa_\infty = \kappa_0 \qquad (50)$$

At zero frequency, that is, when $\omega = 0$, equation (47) gives

$$\kappa_{\omega=o} = \kappa_1 + \Delta\,\kappa = \kappa_f \qquad (51)$$

which also agrees with the assumptions made above.

The variable term in equation (48) becomes equal to zero both at $\omega = 0$ and at $\omega = \infty$. This agrees with the physical conception of this term, as giving the apparent time effect of absorption. The power loss per unit volume is $G_{eff}^2\,\gamma_\omega$. Subtracting from this the true conduction loss $G_{eff}^2\,\gamma_f$, gives the dielectric loss per unit volume at frequency ω:

$$P_\omega = G_{eff}^2\,(\gamma_\omega - \gamma_f) \qquad (52)$$

Thus, the observed power loss corrected for true conduction and plotted against ω as abscissas gives some information in regard to the shape of the function $F(\alpha)$.

For the circuit represented by equation (45), we have

$$\tan\psi = \frac{g}{\omega\, C} \qquad (53)$$

where the *loss* or *imperfection angle* ψ is complementary to the phase angle between the voltage and the current. Knowing ψ, the value of sin ψ can be found, and this value is the power factor of the condenser. Applying equation (53) to our case, we have

$$\tan\psi_\omega = \gamma_\omega/(\omega\,\kappa_\omega) \qquad (54)$$

where κ_ω and γ_ω are determined by equations (47) and (48). Knowing ψ_ω, we find,

$$\text{Power factor} = \text{Sin}\ \psi_\omega \qquad (55)$$

Dielectric loss increases considerably with temperature[6]. In the present investigation, the temperature of the sample is assumed to be the same throughout its thickness and, in checking experimental data with theoretical formulas, it is of importance to see that this condition has been at least approximately fulfilled during the tests.

Transient Voltages. The theory developed above for an established direct voltage may be extended to include a short d-c. impulse, or a combination of such impulses, by using the principle of superposition. For example, if a voltage E is applied at the instant t_1 and removed at the instant t_2, the conditions are the same as if the voltage E were continued from $t = t_1$ to $t = \infty$ and a voltage $-E$ applied from $t = t_2$ to $t = \infty$. It is also possible that the Heavisidian operational calculus may be applied to the solution of this problem.

If the applied transient voltage is of the nature of a decremental sine wave, equation (41) may be used for G_τ, in which ω is a complex quantity. The lower limit of τ is no longer $-\infty$ and equation (42) has to be integrated anew. Of course, equations (31) and (32) can be used directly for any transient voltage provided that G_τ is given as a function of τ.

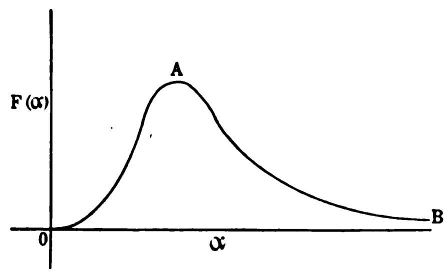

FIG. 5—THE GENERAL CHARACTER OF THE DISTRIBUTION FUNCTION $F(\alpha)$

4. A DISTRIBUTION FUNCTION $F(\alpha)$ AND THE CONDITIONS WHICH ITS PARAMETERS MUST SATISFY

A reasonable shape of the function $F(\alpha)$ for a fairly homogeneous dielectric is shown in Fig. 5. A large number of particles have values of α within the range near the maximum of the curve. There are fewer and fewer particles as one chooses values of α more remote from this range. The curve passes through the origin and may or may not be tangent to the axis of abscissas there; it should approach the axis of abscissas asymptotically at infinity. Probably several analytical functions would give a curve of this shape, and the selection of a particular function, in so far as there are no more valid theoretical grounds, is mainly determined by the following considerations:

a. General simplicity.

b. Ease in the integration of various expressions such as equations (38), (47), etc.

c. A sufficient number of parameters to fit the observed behavior of a given dielectric.

6. See, for example, L. Dreyfus, Mathematische Theorien für den Durchschlag fester Isoliermaterialien; *Schweiz. Elektrot. Verein, Bulletin*, 1924, Vol. 15, p. 321.

As a fundamental empirical expression, we shall take

$$F(\alpha) = H\alpha^{m-1}\epsilon^{-n\alpha} \qquad (56)$$

where H, m, and n, are constants independent of α. These constants are different for different materials and, for a given material, are functions of temperature.

The physical dimension of $\phi(t)$ is a numeric; see its definition, equation (8). According to equation (25), the physical dimension of α is (time)$^{-1}$, because the product αt must be a numeric. Consequently, the physical dimension of $F(\alpha)$ must be "time," because the product $F(\alpha)\,d\alpha$ must be a numeric. In equation (56), $n\alpha$ must be a numeric, hence the dimension of n is "time." The exponent m is a numeric, and the dimension of H is (time)^m. It will be seen later that H is eliminated from the final computations.

Taking a derivative of $F(\alpha)$ with respect to α, we get

$$dF(\alpha)/d\alpha = H\alpha^{m-2}\epsilon^{-n\alpha}(m-1-n\alpha) \qquad (57)$$

With the aid of equations (56) and (57), the limiting values of m and n may be determined as follows:

(a) As α approaches zero, $\epsilon^{-n\alpha}$ approaches unity for any finite value of n. Hence, α^{m-1} should approach zero in order that the curve pass through the origin. This gives the first limiting condition, namely, $m > 1$. But for values of m less than 2, equation (57) gives infinite values of the slope, showing that the curve is tangent to the axis of ordinates. This does not agree with the assumed character of the phenomenon. At $m = 2$, the value of the right-hand side of equation (57) is H.

This may be accepted (at least provisionally) as a possible value, so that

$$m \geqq 2 \qquad (58)$$

(b) At infinity, the term α^{m-1} tends to an infinitely great value, while $\epsilon^{-n\alpha}$ tends to zero, provided that n is positive. Moreover, since an exponential expression ϵ^{α} tends to infinity at a higher rate than any positive power of α, the ratio $\alpha^{m-1}/\epsilon^{n\alpha}$ approaches zero when $\alpha = \infty$.

Equation (57) gives a zero slope at $\alpha = \infty$. Thus, the second limiting condition is

$$n > 0 \qquad (59)$$

(c) The last factor in expression (57) becomes zero when

$$\alpha = (m-1)/n \qquad (60)$$

At this value of α, the function $F(\alpha)$ reaches its maximum. Equation (60) may have some bearing upon the selection of values of m and n, or upon the interpretation of experimentally obtained values.

(d) Substituting expression (56) in equation (26) and integrating, we get[7]

$$H\int_0^{\infty}\alpha^{m-1}\epsilon^{-n\alpha}\,d\alpha = H\,\Gamma(m)/n^m = 1 \qquad (61)$$

from which

$$H\,\Gamma(m) = n^m \qquad (62)$$

7. B. O. Peirce, Short Table of Integrals, formula 493.

where Γ stands for the so-called Gamma Function[8].

Thus, the quantities H, m, n, are not entirely independent of one another, but must satisfy equation (62).

(e) Substituting expression (56) in equation (40) and integrating gives

$$H\int_0^{\infty}\alpha^{m}\epsilon^{-n\alpha}\,d\alpha = H\,\Gamma(m+1)/n^{m+1}$$
$$= (\gamma_0 - \gamma_f)/(\kappa_f - \kappa_0) = \Delta\gamma/\Delta\kappa \qquad (63)$$

from which

$$H\,\Gamma(m+1) = n^{m+1}\,(\gamma_0 - \gamma_f)/(\kappa_f - \kappa_0)$$
$$= n^{m+1}\,\Delta\gamma/\Delta\kappa \qquad (64)$$

This condition imposes another limitation upon the choice of the quantities H, m, and n. There is an additional connection between equations (62) and (64) because

$$\Gamma(m+1) = m\,\Gamma(m)\,{}^{9} \qquad (65)$$

Dividing equation (64) by equation (62), and using expression (65), we get

$$m/n = (\gamma_0 - \gamma_f)/(\kappa_f - \kappa_0) = \Delta\gamma/\Delta\kappa \qquad (66)$$

The function (56) is different from that chosen by Wagner. He used the so-called probability function for the distribution of values of relaxation time[10]. There is no valid theoretical reason for selecting this function in preference to any other, even for a chemically simple and strictly homogeneous material. With actual substances, of complicated molecular structure and with impurities, such a function is totally inadequate, since it has not a sufficient number of parameters to fit experimental curves. Therefore, Wagner had to form a function consisting of a sum of a "finite number" of probability functions of different parameters, each giving a different most probable value of the relaxation time. However, if one has to resort to such a summation, then any other function of reasonable shape, such as equation (56), will do just as well.

The probability function leads to quite complicated integrations, and equation (56) offers considerable advantages in this respect, although two of the integrals also lead to infinite series when m is not an integer. In any event, it seems advisable to carry the theory through on the basis of equation (56), for such practical applications and interpretations of tests as it may lead to.

Methods of High Quality Recording and Reproducing of Music and Speech based on Telephone Research

BY J. P. MAXFIELD[1] and H. C. HARRISON[1]
Member, A. I. E. E. Associate Member, A. I. E. E.

Synopsis.—*The paper deals with an analysis of the general requirements of recording and reproducing sound, with the nature of the inherent limitations where mechanical records are used, and a detailed description of a solution involving, first, the use of electrical equipment for the purposes of recording and, second, the use of mechanical equipment based on electric transmission methods for reproducing.*

Probably the most useful feature of the paper is the complete description of the application of electrical transmission theory to mechanical transmission systems. A detailed analysis is made of the analogies between the electrical and the mechanical systems.

INTRODUCTION

THE problem with which this paper is concerned, in its broadest sense, may be stated as that of taking sound from the air, storing it in some permanent way and reproducing it again without appreciable distortion. It is immaterial from the general standpoint whether the means used are mechanical or electrical or a combination of the two. The choice of which method to use will depend largely upon the commercial requirements accompanying the specific purpose for which the reproduction is being made. For instance, it is quite probable that the means chosen for reproduction in residences would differ materially from those used in large ballrooms or in the presentation of synchronized motion pictures.

Before considering the methods and results referred to in the title of this paper, it may be well to make a rough division of the problem. The storing or recording of sound requires, first, a mechanical system which will respond faithfully to the sound waves which are to be recorded. Then, there is required some material in or on which this sound may be recorded and an intervening system which permits the sound waves to make the record in this material. In the usual case, and in that with which we are particularly concerned here, there is a mechanical system which will vibrate in response to the sound which is to be recorded and

1. Both members of the technical staff, Bell Telephone Laboratories.

Abridgment of a paper presented at the Midwinter Convention at the A. I. E. E., New York, N. Y., February 8-11, 1926. Complete copies available upon request.

directly through some mechanical linkage or less directly through an electrical linkage, drive a cutting mechanism which will impress a wax record.

The first consideration, therefore, is the character of the sound which is to be recorded including all of the effects of reverberation and the general questions of studio design. Next to be considered is the manner in which the cutting instrument shall impress this speech or musical record upon the constantly rotating wax disk, which disk is commonly called the wax master. In this connection, there will be discussed also the relative value of the electrical and mechanical linking of the cutting knife with the mechanism which receives the sound waves. Following the discussion of these problems and a brief reference to the state of the prior art, there remains to be considered the reproduction of the sound which is stored in the cuts or grooves of the wax record.

In the case of reproduction also, there is required a mechanical system which will respond to these cuts in the wax and a system which will set up in the air-sound waves essentially identical to those picked up by the first mechanism of the recording system. Between these two systems, a mechanical linkage intervenes in the case under discussion, but reference is made to the relative advantages of this system compared with the use of an electrical linkage.

First to be described, is the character of the sound which is to be recorded and reproduced and the effects of reverberation and transients upon the listener's sensation of this sound.

Studio Characteristics and Transients

Phonographic reproduction may be termed perfect when the components of the reproduced sound reaching the ears of the actual listener have the same relative intensity and phase relation as the sound reaching the ears of an imaginary listener to the original performance would have had. Obviously, it is very difficult, if not impossible, to fulfill all of these requirements with a single channel system, that is, with a system which does not have a separate path from each ear of the listener to the sound source.

The use of two ears, that is, two-channel listening, gives the listener a sense of direction for each of the various sources of sound to which at a given moment he may be listening, and, therefore, he apprehends them in their relative distribution in space. It has been found possible with a single channel system, however, by controlling the acoustic properties of the room in which the sound is being recorded, to simulate to a considerable degree in the reproduced music the effective space relationships of the original. In this case, with a one-channel system, the directional effect is, of course, entirely absent, and the spatial relationship which is apprehended is probably due to the increased apparent reverberation of the instruments situated at the far end of the room as compared with those in the near foreground.

In recording work, therefore, one of the important acoustic characteristics of a room is its time of reverberation. Although it is probable that this is the most comprehensive single factor, experiment has shown that the shape of the room and the distribution and character of the damping surfaces play a part in the excellence of music in such a room.

It has been shown by Sabine[2] that for piano music, studios should have a time of reverberation measured by his method of 1.08 seconds. Experience has indicated that this figure is also very closely correct for other types of music. This figure of Sabine's assumes binaural listening. With single-channel systems, such as most of the present reproduction systems, whether for radio or the phonograph, the ability of the listener to separate the reverberation from the direct music by means of the sense of direction is completely removed and there is thrust upon his attention an apparently excessive amount of room echo. Experiment has shown that a time of reverberation for the recording room ranging from slightly more than ½ to slightly less than ¾ of Sabine's figure affords in the reproduced music the effect of a room with proper acoustics. When this effect is accomplished, the person listening to the reproduced music has the consciousness of the music being played in a continuation of the same room in which he is listening and also has a sense of spatial depth.

Experiment has indicated further that any transients set up by the recording or reproducing system constitute a second cause of apparent increased reverberation. The data obtained thus far are insufficient to permit assignment of quantitative values to the importance of these two factors.

At the present state of the art, the most important requirement of a recording or reproducing system is its frequency characteristic. This involves two factors—intensity versus frequency, and phase distortion versus frequency. The effect of the second of these factors is not thoroughly understood but as it is closely related to the production of transients it has to be considered, as mentioned above. The system to be described is, however, relatively free from violent phase shifts within most of the range covered, but does have some undesirable phase-shift characteristics with small accompanying transients near its limiting cut-off frequencies.

Frequency Requirements

The frequency range which it would be desirable to cover if, it were possible, with relatively uniform intensity for the transmission of speech and all types of music including pipe organ is from about 16 cycles per second to approximately 10,000.

2. Collected papers of W. Sabine.

It may be interesting to examine the record requirements for a band of frequencies this great. For the purpose of this illustration, a lateral cut record will be assumed although in all the factors except the time which the record will run, the arguments apply in a similar manner to the hill-and-dale cut. Since, for mechanical reproduction, the sound at a given pitch is radiated by means of a fixed radiation resistance, it is necessary that the record must be cut with a device the square of whose velocity is proportional to the sound power. Under these conditions, it is seen that for a given intensity of sound the amplitude is inversely proportional to the frequency of the tone, and that a point will be reached somewhere at the low end of the sound spectrum where this amplitude will be great enough to cut from one groove into the adjacent groove, or in case of vertical cut, to cut so deeply that with present materials the wax will tear instead of cut away with a clean surface. This means that there is an inherent maximum amplitude beyond which it is not commercially feasible to go. Similarly the minimum radius of curvature of sine waves of various frequencies cut at constant velocity is inversely proportional to the frequency, so that as higher and higher frequencies are reached the radius of curvature becomes smaller and smaller until finally it becomes too small for the reproducing needle to follow. There is, therefore, an inherent limit at the upper end.

In order to extend these limits, it is necessary in the case of the low end to make the spiral coarser and in the case of the high end to run the record at a higher speed. Both of these changes tend to decrease the time which a record of a given size can be made to play. The only alternative of these methods is to cut the record less loud than is the present standard practise and make the reproducing equipment more sensitive. This could easily be done if it were not for the "record noise" or "surface noise," as it is commonly called. Since this surface noise is already loud enough in comparison with the reproduced music to be somewhat objectionable, no appreciable gain in this direction can be made until the technique of record manufacture has been distinctly improved.

In this connection, there is one other interesting point. It has been suggested that if electric reproduction were used, it would be possible to cut the record with a characteristic other than uniform velocity sensitiveness and correct for the error by an electrical system whose characteristic is the inverse of the characteristic of record. If the change which is made in the recording characteristic tends toward cutting at uniform acceleration sensitiveness, the amplitude varies inversely as the square of the frequency and hence the difficulties at the low end of the scale are greatly enhanced. Similarly, if the records are cut more nearly at constant amplitude, the radius of curvature of the sine waves decreases as the square of the frequency, hence the difficulties are placed at the upper end. In the process which is being described in this paper, these limitations have been met commercially by having a frequency characteristic of the uniform velocity type between the frequencies of 200 and approximately 4000 cycles per second. Below 200 it has been necessary to operate at approximately constant amplitude with a resulting loss in intensity which loss increases as the frequency decreases. Above 4000 it has been necessary to operate at approximately constant acceleration with its consequent slight loss in intensity at the very high overtones. With a characteristic of this type, a range of frequencies from 60 cycles to 6000 can be recorded with reasonable success although the very low and very high range are slightly deficient. (See Fig. 14) With a record having such a frequency characteristic, the inherent limitations are divided between the two ends of the frequency band and where electrical reproduction methods are used, it is possible to employ a reproduction system whose frequency characteristic compensates for that of the record.

It should be pointed out that an attempt to record notes lower than the low cutoff of the above mentioned apparatus would result in recording only those harmonics of the notes which lie above the cut-off. This in no way prevents the listener from hearing the notes, reproduced by means of the harmonics only, as notes with the pitches of the missing fundamentals although it does somewhat change the quality of the tone.[3] If it were not for this ability of the ear to add the fundamental pitch of a note, of which only the harmonics are being reproduced, most of the older phonographs and loud speakers would have been totally useless for the reproduction of speech and music.

Mechanical Versus Electrical Recording

In attacking the recording part of the problem, two ways at once present themselves; first, the direct use of the power, of the sound being recorded, to operate the recording instrument; and second, the use of high quality electric apparatus with vacuum tube amplifiers in order to give more freedom to the artists and better control to the process. The amount of power available to operate the recorder directly from the sound in the recording room is so small as to make it extremely difficult to make records under natural conditions of speaking, singing, or instrumental playing. As the use of high quality electric apparatus with associated amplifiers has a very distinct advantage over the acoustic method, they have been adopted for the recording part of the process. Fig. 1A shows a picture of a group of artists recording by means of the sound power directly, while Fig. 1B shows a record being made by the same artists with the electric process.

3. Physical Criterion for Determining the Pitch of a Musical Tone, H. Fletcher, *Phys. Rev.*, Vol. 23, No. 3, March, 1924.

It will be noticed in Fig. 1A that the artists are grouped very closely about the horn. In the case of the weaker instruments such as violins, it has been possible to use only two of standard construction. The rest of the violins are of the type known as the "Stroh" violin which is a device strung in the manner of a violin but so arranged that the bridge vibrates a diaphragm attached to a horn. This horn is directed toward the recording horn, as shown by the player in the foregound.

Fig. 1A—Picture of an Orchestra Recording for the Acoustic Process. This Picture was Furnished through the Courtesy of the Victor Talking Machine Company, Camden, New Jersey

With such an arrangement of musicians, it is very difficult to arouse the spontaneous enthusiasm which is necessary for the production of really artistic music.

Fig. 1B—Picture of the Same Orchestra Shown in Fig. 1A, but Recording for the Electric Process. This Picture was Furnished through the Courtesy of the Victor Talking Machine Company, Camden, New Jersey

In Fig. 1B the musicians are sitting at ease more nearly in their usual arrangement and all are using the instruments which they would use were they playing at a concert. Furthermore, the microphone is now sufficiently far away from the orchestra to receive the sound in much the manner that the ears of a listener in the audience would receive it. In other words, it picks up the sound after it has been properly blended with the reflections from the walls of the room. It is in this way that the so-called "atmosphere" or "room-tone" has been obtained.

In the old process, it sometimes happened that after the instruments had been arranged in such a manner that the relative loudness of the various parts had been balanced correctly, it was found that the whole selection was either too loud or too weak. This usually meant a complete rearrangement of the players. With the flexibility introduced by the use of electrical apparatus including amplifiers, the control of loudness is obtained by simple manipulation of the amplifier system and is in no way related to the difficulties of the relative loudness of one instrument to another. The only problem for the studio director in this case is to obtain the proper balance among the various musical instruments and artists. The advantages derived from this added ease of control are also made manifest in that it is much easier and less tiresome for the artists and it is usually possible to make more records in a given time.

Mechanical Versus Electrical Reproducing

Where the question of reproduction is concerned, the same two alternatives mentioned for recording present themselves, namely, direct use of power derived from the record itself versus the use of electromechanical equipment with an amplifier. In this case, however, the situation is a little different as the power which can be drawn directly from the record is more than sufficient for home use. Since any method of reproducing from mechanical records by electrical means involves the use of a mechanical device for transforming from mechanical to electrical power and a second such device for transforming from electrical back to mechanical power, that is, sound, it is necessary to use two mechanical systems, one at each end of an electrical system. Where the power which can be supplied by the record, is sufficient to produce the necessary sound intensity, as in the case of home use, it is in general simpler to design one single mechanical transmission system than it is to add the unnecessary complications of amplifiers, power supply and associated circuits. In cases where music is to be reproduced in large auditoriums, the power which can be drawn from the record may be insufficient and some form of electric reproduction using amplifiers becomes necessary.

Brief Description of Recording System

The system used for recording consists of a condenser transmitter, a high quality vacuum tube amplifier and an electromagnetic recorder. Fig. 2 shows the calibration of the condenser transmitter and the associated amplifiers. The condenser transmitter and amplifiers are so designed that the current delivered to the recorder circuit is essentially proportional to the sound pressure at the transmitter diaphragm. The electromagnetic recorder, which will be described later, is designed to work with this type of system.

With the exception of this electromagnetic recorder, apparatus of this type has already been described in the literature.[4] In addition to this equipment which might be called the recording amplifier system, there is a volume indicator for measuring the power which is being delivered to the recorder and also an audible monitoring system. The audible monitoring system consists of an amplifier whose input impedance is high compared with the recorder impedance and a suitable loud speaking receiver. The monitoring amplifier is bridged directly across the recorder and operates the loud speaking receiver so that the operator may listen to the record as it is being made.

In the design of the recording and reproducing systems each part of the system has been made as nearly perfect as possible. Errors of one part have not been designed to compensate for inverse errors in another part. Although this method is the more difficult, its flexibility, particularly as regards the commercial possibilities of future improvements justifies the extra effort.[5] There is, therefore, no distortion in the record whose purpose is to compensate for errors in the reproducing equipment; the only intended distortion in the record being that required by the inherent limitations mentioned above. See Figs. 2, 14 and 20.

General Basis of Design

An interesting feature of the development of the mechanical and electromechanical portions of the recording and reproducing system is their quantitative design as mechanical analogs of electric circuits. Both the recording and reproducing systems are good examples of the use of this type of analogy.

The economic need for the solution of many of the problems connected with electric wave transmission over long distances coupled with the consequent development of accurate electric measuring apparatus has led to a rather complete theoretical and practical knowledge of electrical wave transmission. The advance has been so great that the knowledge of electric systems has surpassed our previous engineering knowledge of mechanical wave transmission systems. The result is, therefore, that mechanical transmission systems can be designed more successfully if they are viewed as analogs of electric circuits.

While there are mechanical analogs for nearly every form of electrical circuit imaginable, there is one particular class of electrical circuits whose study has led to ideas of the utmost value in guiding the course of the present development. This class of circuits consists of infinitely repeated similar sections of one or more lumped capacity and inductance elements in series and shunt and are commonly known as filters. The study of filters began with the work of Campbell[6] and a recognition of their importance as frequency selective systems in telephone repeaters, carrier systems, radio, signalling systems, etc., led to their intensive study. In the available literature is to be found a fairly complete statement of their properties and details of their design.[6]

It will be recalled in the case of the telephone circuit that the introduction of inductance coils at regular intervals in the circuit produced a remarkable change in the transmission characteristic. Over a broad band of frequencies the attenuation was reduced and made fairly uniform over that range while beyond a critical frequency called the cut-off frequency the attenuation became very high. In the ideal filters with zero dissipation the transmission characteristics are of the same nature but more clear cut. Structures of this type with infinitely repeated sections will have one or more transmission bands of zero attenuation and one or more bands having infinite attenuation. The impedance characteristics of such a structure measured from certain characteristic points will be pure resistance more or less uniform in the transmission bands, and pure reactance in the attenuation bands. These terminations are

mid-series; that is, the entering element being a series one of half the normal series element; or mid-shunt; that is, the entering element being twice the impedance of the normal shunt element. The corresponding impedances are called the mid-series and mid-shunt characteristic or iterative impedances.

If we retain the first few sections of such a structure

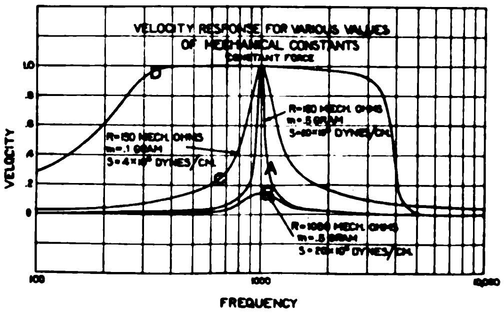

FIG. 9—VELOCITY. RESPONSE FOR VARIOUS VALUES OF MECHANICAL CONSTANTS

and terminate them with a resistance which is equal to the resistance impedance of the infinite line from which they were taken, the characteristics are substantially unchanged. It is understood, of course, that this resistance equals approximately the resistance impedance of the remainder of the infinite line at most of the frequencies in the transmission band in which we are interested.

The presence of small amounts of damping in the various elements also has but slight effect on the general characteristics. These results could in general be readily applied to the various telephone transmission problems because the source and load between which the filter system was inserted generally had or could be made to have a nearly resistance impedance equalling the mid-series or mid-shunt impedance of the filter within the transmission band. The filter and terminating impedances may then be said to be matched. Where adjacent sections in the filter have impedances similar in character but different in absolute magnitude they may be joined by a suitable transformer.

Many early attempts were made to design mechanical transmission systems having a wide frequency range in which highly damped single or multi-resonant systems were employed. In these attempts both of the obvious methods of increasing the damping were used, namely, that of adding a resistance to the system and that of increasing the value of the compliance and decreasing mass in such proportion as to maintain the same natural frequency. The former of these methods reduces the sensitivity of the system at the point where it is most efficient, (See Fig. 9), while the second method increases the response at the points where the system is less sensitive, namely, away from its resonance point. Fig. 9 shows four curves—first, a singly resonant system, Curve A; second, the same system with friction added, Curve B; third, the same system without the added friction but with an increase in compliance and a decrease in mass such that the natural period remains the same; Curve C, and fourth, a band pass type of circuit whose resistance impedance is the same as that of the system shown in Curve A. (See Curve D.)

The results of filter theory have shown how these resonances should be coordinated so that when a proper resistance termination is used high efficiency and equal sensitivity are obtained over a definite band of frequencies by elimination of response to all frequencies outside the band. With the electrical case of a repeated filter, each section considered by itself resonates at the same frequency but when combined into a short-circuited filter of n sections, there will be n natural frequencies. However, when such a system is terminated with a resistance which equals the nominal characteristic impedance in the transmission band, uniform response in the terminating resistance is obtained over the entire band.

DETAILED ANALYSIS OF MECHANICAL AND ELECTRICAL ANALOGS[7]

Before going on with a detailed treatment of the electrical analogues of the mechanical structures used in the problem of phonographic reproduction, a list of the corresponding quantities used in the two systems will be given, together with the symbols employed.

Mechanical		Electrical	
Force	= F (dynes)	Voltage	= E (volts)
Velocity	= v (cm./sec.)	Current	= i (amperes)
Displacement	= s (cm.)	Charge	= q (coulombs)
Impedance or mechanical ohms)	= z (dyne sec./cm.	Impedance	= Z (ohms)
Resistance	= r (dyne sec./cm.)	Resistance	= R (ohms)
Reactance	= x (dyne sec./cm.)	Reactance	= X (ohms)
Mass	= m (gms)	Inductance	= L (henries)
Compliance	= c (cm./dyne)[8]	Capacity	= C (farads)

General Design of Mechanical Systems

In designing mechanical systems of the band pass type, the problem is three fold—first, that of arranging the masses and compliances such that they form repeated filter sections; second, determining the magnitude of these quantities so that with or without transformers the separate sections all have the same cut-off frequencies* and characteristic impedances; third, to provide the proper resistance termination. Where the transmitted mechanical power has not been radiated as sound this third part has been one of the most difficult to fulfill.

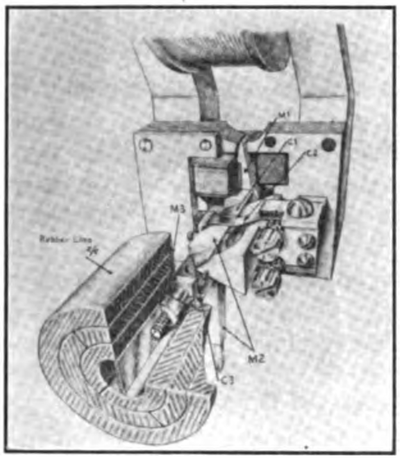

Fig. 11—Detailed Drawing of the Mechanical Filter of an Electromagnetic Recorder. (Lettering Same as in Fig. 12)

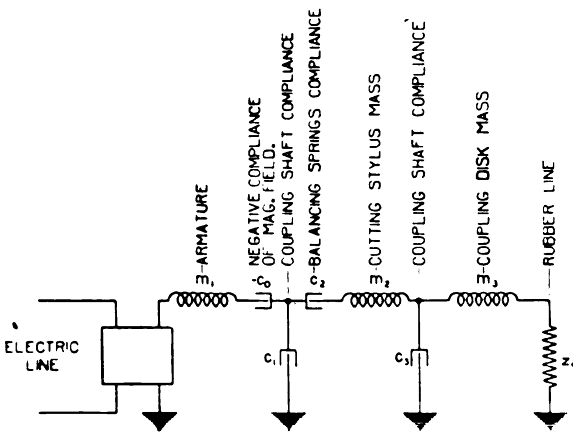

Fig. 12—Equivalent Electric Circuit of the Electromagnetic Recorder

In designing these systems, practical difficulties arose—first, the difficulty of insuring that the parts vibrated in the desired degrees of freedom only, and second, the difficulty of determining the magnitudes of the various effective masses, compliances and resistances. Before the work to be described could be carried out practically it became necessary to develop a method of measuring mechanical impedances[10]. This method of measurement has been very useful not only in determining the magnitudes of the impedances in the degrees of freedom in which it is desired that they shall operate, but in determining the impedances to motion of the various parts in directions in which they should not be permitted to vibrate. In connection with the measurement of the magnitudes of the parts in the desired degrees of freedom this method enables us to determine the constants of the mechanical networks under their conditions of operation. Experience so far has indicated that when all the degrees of freedom have been taken into account and when the dynamic axes of vibration have been properly chosen, the static and dynamic constants of the parts are the same, and it is then possible to check the parts by simple static measurements. In the early attempts to build these systems very large discrepancies between the static and dynamic characteristics were found.

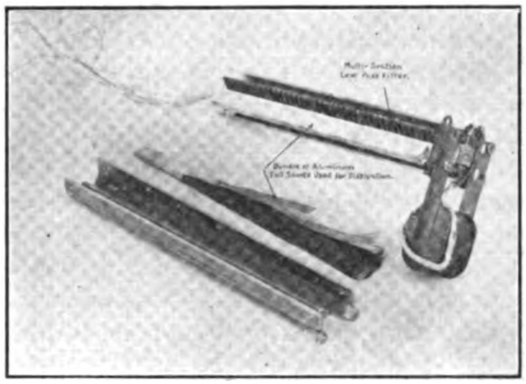

Fig. 13—Electromagnetic Recorder using Lumped Loaded Termination

The method of furnishing dissipation to the lumped loaded line is shown

The Recorder

One of the early practical phonographic applications of electric filter design to mechanical problems was the development of an electromagnetic recorder. The instrument as finally constructed is essentially a properly terminated three-section mechanical filter in which the recording stylus and its holder constitute the series mass in the second section. Since a filter of this type appears at its input end as approximately a pure resistance within the transmission band, the current in the series inductances, that is, in the mechanical

*It is of course permissible to have a section having a higher cut-off than the others provided its characteristic impedance is the same as that of the others over the transmission band of those having the lower cut-off.

10. Kennelly, A. E. and Affel, H. A., "The Mechanics of Telephone Receiver Diaphragms, as Derived from their Motional Impedance Circles," *Proc.* A. A. A. S., Vol. 51, No. 8, November, 1915.

case, the velocity of the series masses is proportional to the driving force.

Figs. 10, 11 and 12 show respectively, a complete recorder, a drawing of the mechanical filter of such a recorder and a diagram of the equivalent electric circuit.

Referring to Figures 11 and 12, all of the equivalents can readily be seen with the exception of the terminating resistance and the negative compliance, c_0. The reason for using the type of termination shown lies in the fact that most of the known mechanical resistances have values which are functions of frequency or of amplitude or of both. Also in most cases, the mechanical resistance is accompanied by either a mass or compliance reactance. By using a continuous transmission line (shown completely in Fig. 10 and partially in Fig. 11) which line is sufficiently long so that a wave entering it will be essentially absorbed before it has reached the far end, been reflected and returned to the entering end, it has been possible to use imperfect types of damping for this line and still

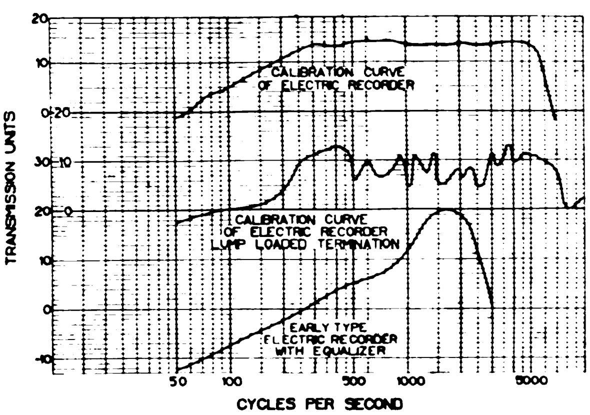

FIG. 14—CALIBRATION CURVE OF THREE TYPES OF ELECTROMAGNETIC RECORDERS

obtain over the desired band, an essentially pure resistance at the input end.

Fig. 14 shows calibration curves of three types of recorders. The bottom curve shows an early type of highly damped singly resonant system. The middle curve is a calibration of a low pass mechanical filter type using lumped loading in the resistance line.* The upper curve shows the calibration of the recorder shown in Fig. 10.

The compliance $-c_0$ is a mechanical quantity for which there is no simple electric analog. In a balanced armature type of structure such as that shown in Fig. 11, the action of the field on the armature, when it is at its center point, is balanced. If, however, the armature be deflected, a small distance from this equilibrium, there is exerted by the magnetic field a torque tending to pull the armature further away from its center position. The value of this torque for small amplitudes is proportional to the angular displacement. It is therefore seen that this quantity is of the nature of a compliance but that the back force is in a reverse direction to that required for a positive compliance.

*For a description of this, see the complete paper available in pamphlet form upon request.

DESIGN OF THE REPRODUCING APPARATUS

As the analogy between the mechanical and electrical filter is more perfectly shown in the case of the reproducing equipment, the detailed quantitative descrip-

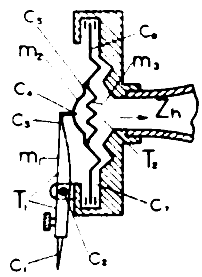

FIG. 15—DIAGRAMMATIC SKETCH OF THE MECHANICAL SYSTEM OF THE PHONOGRAPH

tion will be given in this connection. Figs. 15 and 16 show respectively a diagram of the reproducing system and its equivalent electric circuit. From these diagrams it is evident which units in the mechanical system correspond to the various electrical parts. As the series compliances c_2, c_4 and c_6 have been made so large that the low frequency cut-off caused by them lies well below the low frequency cut-off of the horn, an inappreciable error is introduced in using for design

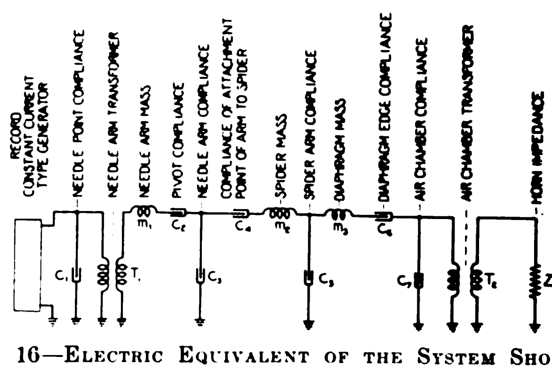

FIG. 16—ELECTRIC EQUIVALENT OF THE SYSTEM SHOWN IN FIG. 15

purposes formulas of low pass filters[11]. The two formulas which will be used are as follows:

$$f_c = \frac{1}{\pi} \sqrt{\frac{1}{m\,c}} \qquad (12)$$

Where

f_c = cut-off frequency of a lumped transmission system in cycles per second

11. Campbell, G. A., "On loaded lines in Telephonic Transmission," *Phil. Mag.*, March, 1903.

c = shunt compliance per section in centimeters per dynes

m = series mass per section in grams

$$z_0 = \sqrt{\frac{m}{c}} \qquad (13)$$

Where z_0[12] is the value of characteristic impedance over the greater part of the band range.

Equations (**12**) and (**13**) which form the basis of the design work contain four variables, f_c, c, m and z_0. It is, therefore, necessary to determine two of them by the physical requirements of the problem after which the other two are determined. The upper cut-off frequency f_c was arbitrarily chosen at 5000 pps. as a compromise between the highest frequency occurring on the record and the increase in surface noise as the cut-off is raised. The choice of the other arbitrarily set variable came after considerable preliminary experimenting and was fixed by the difficulty of obtaining a diaphragm which is light enough and has a large enough area. Hence the effective mass of the diaphragm m_3, (Figs. 15-16) was fixed at 0.186 grams which value can be obtained by careful design. The effective area can be made as large as 13 square centimeters. For convenience let the arbitrary value chosen for $f_c = \bar{f}_c$ and the value of $m = \bar{m}_3$.

Solving Equations (**12**) and (**13**) for c and z_0, we get

$$c = \frac{1}{\pi^2 \bar{f}_c^2 \bar{m}_3} \qquad (14)$$

$$z_0 = \pi \bar{f}_c \bar{m}_3 \qquad (15)$$

also

$$z_0 = \frac{1}{\pi c \bar{f}_c} \qquad (16)$$

In order to obtain the low value of mass mentioned, with a large enough area, it was necessary to make the diaphragm of a very stiff light material. An aluminum alloy sheet 0.0017 in. thick was chosen and concentrically corrugated as shown in Figs. 17 and 18. These corrugations are spaced sufficiently close so that the natural periods of the flat surfaces are all above $\bar{f}_c$. To insure that this central stiffened portion should vibrate with approximate plunger action, which is more efficient than diaphragm action, it is driven at six points near its periphery.

Reference to Figs. 15 and 16 and Equation (**14**) shows that the compliance of the air chamber c_7, of the spider legs c_5 and shunt tip of the needle arm c_3 are determined. Also the mass of the spider m_2 and the effective mass of the needle arm m_1, as viewed at the point where it is attached to the spider, are determined.

The impedance looking into the system from the record is determined by the rate at which it is necessary to radiate energy in order that the reproduction may be loud enough. The power taken from the record is approximately $v^2 z_0$ since z_0 is a resistance over most of the band. Experiment has shown this value of z_0 to be approximately 4500 mechanical ohms.

But substituting in Equation (**13**) the value of $\bar{m}_3$, and from Equation (**14**) the value of c_5, we find that the impedance is only 2920 mechanical ohms. It is, therefore, necessary to use a transformer whose impedance ratio is $\frac{4500}{2920}$. From this and a knowledge of filter structures the needle-point compliance can be determined. The value obtained is easily realized with commercial types of needle.

It will be noted that the record is shown in Fig. 16 as a constant current generator, *i. e.*, a generator whose impedance appears high as viewed from the needle point. That this is necessary is obvious when it is remembered that, if the impedance looking back into the record were to equal the impedance of the filter system, the walls of the record would have to yield an amount comparable with one-half the amplitude of the lateral cut. This would cause a breakdown of the record material with consequent damage.

The design of the system is, therefore, complete except for the resistance termination which is supplied by the horn for all frequencies above its low frequency cut-off. The characteristics of the horn will be dealt with later. The resistance within the band looking in at the small end of the horn is $G A_2$ where G = mechanical ohms per square centimeter of an infinite cylindrical tube of the same area, and A_2 = area in square centimeters of the small end of the horn.

Let A_1 = the effective plunger area of the diaphragm (as previously mentioned this is 13 sq. cm.). The impedance looking back at the diaphragm is

$$z_0 = \pi \bar{f}_c \bar{m}_3 = 2920 \text{ mechanical ohms}$$

from Equation (**15**), and the impedance looking at a horn whose small end area equals A_2 is

$$z_h = r_0 = A_2 G \qquad (17)$$

Substituting

A_2 = 13 sq. cm.

G = 41 ohms per cm.^{2} we get

$z_h = r_0$ = 533 mechanical ohms

This is entirely insufficient so that the air-chamber transformer becomes necessary.

To calculate the necessary ratio of areas on the two sides of the air-chamber transformer, the following formula is needed. The formula assumes the chamber to be relatively small compared with all wave lengths of the

12. z_0 may be called nominal mid-shunt or mid-series impedance. Their actual values in the transmission band being at any frequency f.,

$$\text{mid-series} = z_0 \sqrt{1 - \left(\frac{f}{f}\right)^2}$$

$$\text{mid-shunt} \quad \frac{z_0}{\sqrt{1 - \left(\frac{f}{f_c}\right)^2}}$$

sound to be transmitted, that is, the pressure changes throughout the chamber are substantially in phase.

$$\frac{z_0}{z_h} = \frac{A_1^2}{A_2^2} \qquad (18)$$

Where

z_0 = the impedance of the primary side of the transformer in mechanical ohms

z_h = the impedance on the secondary side of the transformer in mechanical ohms, *i. e.*, the horn impedance

Solving this equation with the aid of Equations (**15**) and (**17**), we get

$$A_2 = \frac{G\,A_1^2}{\pi\, f_c\, m_3} \qquad (22)$$

(A more complete description of this part of the design is given in the complete paper which will be published in the A. I. E. E. TRANSACTIONS for 1926.)

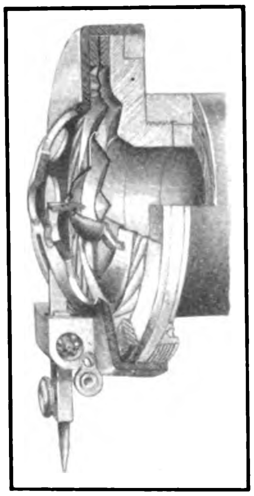

FIG. 18—SECTIONAL DRAWING SHOWING CONSTRUCTION OF THE SYSTEM SHOWN IN FIG. 17

The horn which has been used as a terminating resistance to the mechanical filter structure is a logarithmic one. The general properties of logarithmic horns have been understood for some time.[13]

There are two fundamental constants of such a horn—the first is the area of the large end and the second the rate of taper. The area of the mouth determines the lowest frequency which is radiated satisfactorily. The energy of the frequencies below this is largely reflected if it is permitted to reach the mouth.

From the equations given by Webster,[13] it can be shown that all logarithmic horns have a low frequency cut-off which is determined by the rate of taper. If the rate of taper is so proportioned that its resulting cut-off prevents the lower frequencies from reaching the horn mouth, the horn will then radiate all frequencies reaching its mouth and very little reflection will result.[14] It is, therefore, possible to build a horn having no marked fundamental resonance.

Since the characteristics of the horn are determined by the area of its mouth and by its rate of taper the length of the horn is determined by the area of the small end. This area is determined in turn by the mechanical impedance and effective area of the system

which it is terminating, as shown in Equation (22). It is seen, therefore, that the length of the horn should not be considered as a fundamental constant. A paper describing the design of horns based on these principles is being prepared.

An interesting feature of the horn which has been built commercially is its method of folding. The sketch in Fig. 19 shows a shadow picture of the horn. It will be noticed that the sound passage is folded only in its thin direction, which permits the radius of the turns to be small and thereby makes the folding compact.

Fig. 20 shows the frequency characteristic of a phonograph designed as shown above with a logarithmic horn whose rate of taper and area of mouth opening place the low cut-off at about 115 cycles. It also shows the characteristics of one of the best of the old style phonographs. Curve *A* represents the new machine, while Curve *B* represents the old style standard machine.

Development and Application of Loading for Telephone Circuits

BY THOMAS SHAW[1] and WILLIAM FONDILLER[2]
Member, A. I. E. E. Member, A. I. E. E.

***Synopsis.**—A review of the art of loading telephone circuits as practised in the United States. The introductory section briefly reviews the theory of coil loading, and summarizes the principle characteristics of the first commercial standard loading coils and loading systems, thereby serving as a background for the description of the various improvements of outstanding importance which have been made in the loading coils and loading systems during the past fifteen years to meet the new or changing requirements in the rapidly advancing communication art.*

These major improvements are described in detail under the appropriate headings (1) Phantom Group Loading, (2) Loading for Repeatered Circuits, (3) Incidental Cables in Open-Wire Lines, (4) Cross-talk, (5) Telegraphy over Loaded Telephone Circuits, (6) Loading for Exchange Area Cables, and (7) Submarine Cables. The discussion of these various developments sets forth the relations between the loading features and the associated phases of telephone development, such as the cables, repeaters, telegraph working, and carrier telephone and telegraph systems.

The concluding part of the paper gives some general statistics regarding the extent of the commercial application of loading in the United States, and a brief statement indicative of the large economic importance of loading to the telephone using public.

INTRODUCTION

THE purpose of this paper is to present a review of the art of loading telephone circuits by means of inductance coils inserted at periodic intervals, as practised in the United States. In a paper[3] presented before the Institute in 1911, Mr. B. Gherhardi described the developments in loading up to that time and gave a comprehensive statement of the results obtained. The present paper, therefore, deals primarily with the subsequent developments in the art and their application. The more important improvements which will be considered here, are as follows:

Phantom Group Loading
Loading for Repeatered Circuits
Incidental Cables in Open-Wire Lines
Crosstalk
Telegraphy over Loaded Telephone Circuits
Loading for Exchange Area Cables

Abridgment of paper presented at Midwinter Convention of the A. I. E. E., February 8-11, New York, N. Y. Complete copies to members on application.

THEORY

Viewed from the standpoint of the power engineer, the general effect of loading is to raise the line impedance and improve the power factor. This makes it possible to transmit a given amount of power corresponding to speech sounds at a higher line potential and with a lower value of line current than would be possible without the loading. In the non-loaded line, which is inherently a low impedance line, the series dissipation losses which are proportional to the square of the line current are ordinarily very large relative to the shunt dissipation losses which are proportional to the square of the line potential. Consequently, when the line impedance is increased by a suitable amount, the reduction in series losses is much greater than the increase in shunt losses, and a substantial improvement in line efficiency is obtained. The optimum impedance for minimum line loss is that which results in the shunt and series losses being equal. Ordinarily, it is not economical to apply a sufficient amount of loading to reach this condition.

In general, commercial power lines are electrically short in terms of the wave length of the transmitted frequency, and consequently the sending-end impedance is very largely influenced by the receiving-end impedance. This allows high impedance lines to be

obtained by using high ratio transformers at the receiving end to step up the terminal impedance. On the other hand, telephone lines which are of interest from the loading standpoint are electrically long, and their sending-end impedance is practically unaffected by the terminal impedance. Consequently, the addition of series inductance to the line is the most

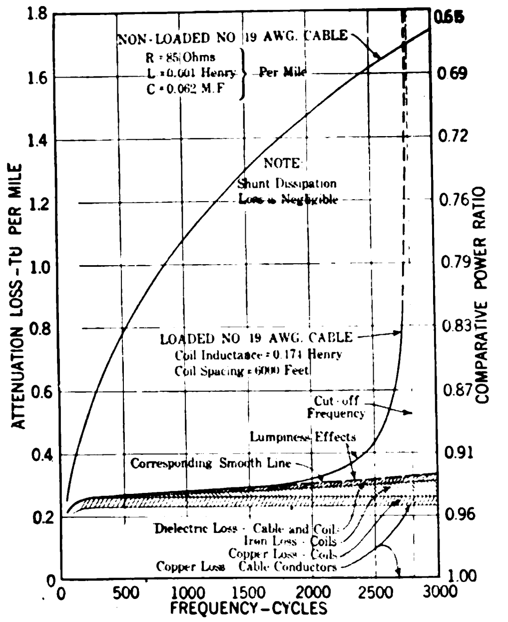

FIG. 1—ATTENUATION-FREQUENCY CHARACTERISTICS OF LOADED AND NON-LOADED NO. 19 A. W. G. CABLE

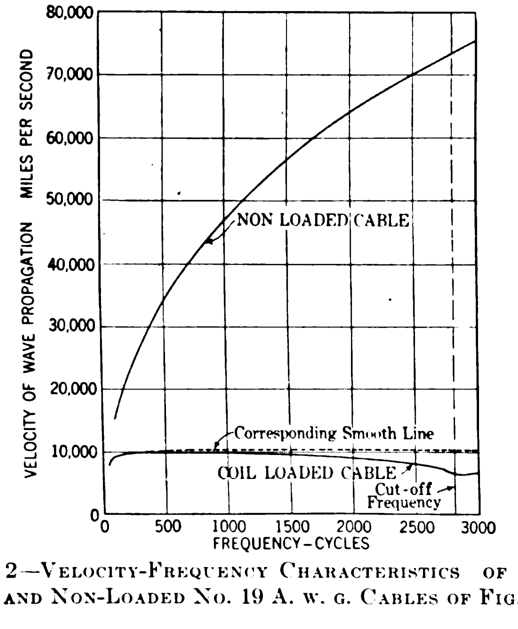

FIG. 2—VELOCITY-FREQUENCY CHARACTERISTICS OF LOADED AND NON-LOADED NO. 19 A. W. G. CABLES OF FIG. 1

practical way of increasing the telephone line impedance.

Besides reducing the line losses and the velocity of propagation, the addition of series inductance makes the attenuation and velocity substantially independent of frequency over the frequency range where the inductive reactance is large relative to the line resistance. This reduction of frequency distortion is especially important in cable circuits, since non-loaded cables have a negligible amount of distributed inductance.

Investigating the question of concentrating the line inductance at uniformly spaced intervals, Professor Pupin gave his famous solution in a paper[4] presented before the Institute in May 1900. Doctor G. A. Campbell, in his paper[5] of March 1903, also gave a mathematical development of the loading theory along somewhat different lines. These early investigations showed the beneficial effects of the lumped inductances and pointed out that these desirable effects hold up to a certain critical frequency which is known as the cutoff frequency, since at this frequency and higher frequencies the attenuatian loss amounts practically to a suppression, due to internal reflection effects. The cutoff

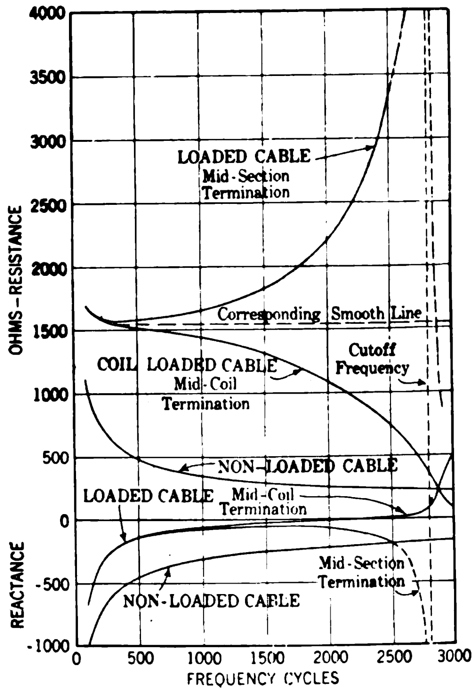

FIG. 3—IMPEDANCE-FREQUENCY CHARACTERISTICS OF LOADED AND NON-LOADED NO. 19 A. W. G. CABLES OF FIG. 1

frequency of a coil loaded line having zero distributed inductance is given by the expression:

$$f_c = \frac{1}{\pi \sqrt{L s C}}$$

in which

f_c = cut-off frequency
L = coil inductance
s = coil spacing
C = line capacitance per unit length

At the cut-off frequency there are two coils per actual

5. *On Loaded Lines in Telephone Transmissions*, G. A. Campbell, *Philosophical Magazine*, March 1903.

wave length, and π coils per wave length in terms of the velocity of the corresponding smooth line. At frequencies above 75 per cent. of the cut-off frequency, the internal reflection effects, sometimes known as "lumpiness effects," are of appreciable magnitude and increase rapidly with rising frequency as the cut-off frequency is approached. At the cut-off frequency, abrupt changes also occur in the velocity and impedance characteristics.

Figs. 1, 2 and 3 illustrate the differences in attenuation, velocity, and impedance characteristics of a typical telephone cable, with and without loading. It is interesting to note that the standard type of loading illustrated in these diagrams so increases the transmission efficiency of No. 19 A. w. g. cable wires that the loaded circuits can be used for distances four times the permissible length of the non-loaded circuits. To obtain this increased transmission range without loading would require wires about eight times as heavy; *i. e.*, No. 10 A. w. g.

Phantom Group Loading

Loading Methods. The Bell System standard methods[6] for loading phantom circuits and side circuits of phantoms are illustrated in Fig. 4.

The loading problem is to introduce the desired inductance into each of the three circuits of a phantom group without causing unbalances which would result in objectionable overhearing or crosstalk effects. The method illustrated in Fig. 4 involves individual loading coils for each telephone circuit, the designs being such that the side circuit coils are substantially non-inductive to the phantom circuit, while the phantom loading coil is substantially non-inductive to each of the side circuits.

Cable Loading. Data regarding the general characteristics of the first phantom group loading systems standardized for use on quadded telephone cables are given in Table V, as follows:

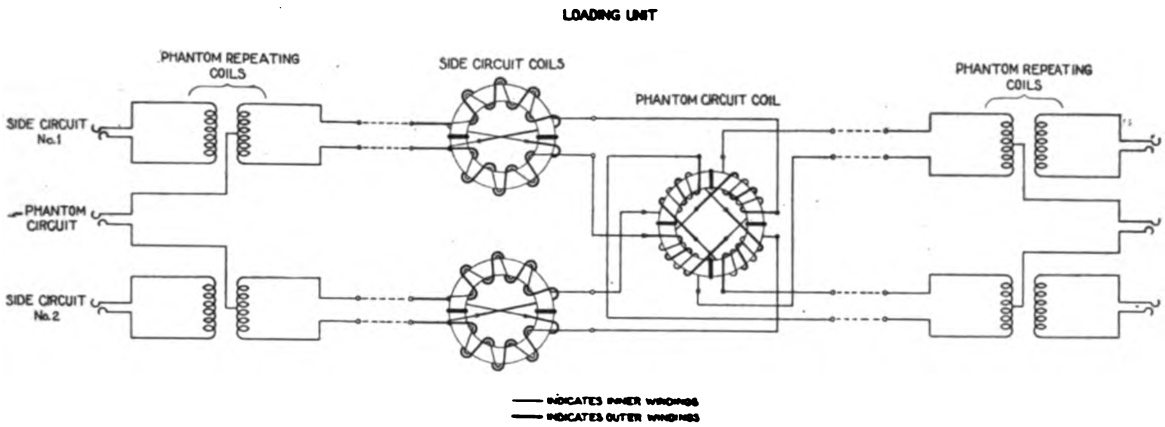

Fig. 4—Bell System Standard Method of Loading Phantom Circuits and Their Side Circuits

TABLE V
FIRST LOADING STANDARDS FOR QUADDED TOLL CABLES

Item	Loading Designation	Type Circuit	Coil Inductance (Henrys)	Coil Spacing (Miles)	Nominal Impedance (Ohms)	Attenuation Loss—TU per mile 19 A. w. g.	16 A. w. g.	13 A. w. g.	10 A. w. g.
1	Medium-Heavy	Side	0.210	1.4	1500			0.085	0.050
2	" "	Phantom	0.130	1.4	950			0.069	0.040
3	Heavy	Side	0.250	1.25	1850			0.081	0.050
4	"	Phantom	0.155	1.25	1150			0.066	0.042
5	Heavy	Side	0.250	1.25	1850	0.24	0.14		
6	"	Phantom	0.155	1.25	1150	0.20	0.12		
7	Medium	Side	0.175	1.75	1300	0.31	0.17		
8	"	Phantom	0.106	1.75	800	0.26	0.14		

Notes: A capacitance of 0.062 μf. per mile is assumed in side circuits and 0.100 μf. per mile in the phantom circuit. The pair capacitance value is smaller than that assumed in Table II. due to improvements in the cables.
All of the above loading systems have a cut-off frequency of about 2300 cycles.

Loading Coils. Table VII gives general information regarding the first standard side circuit and phantom coils used in the phantom group loading systems listed in Table V. The coils designed for No. 10 A. w. g. cable had 65-permeability wire cores and stranded copper windings. The coils designed for No. 13 A. w. g. cables had 65-permeability wire cores and non-stranded copper windings. The coils for Nos. 16 and 19 A. w. g. cables had 95-permeability wire cores.

Loading for Repeatered Circuits

General. In the development of telephone repeaters to the point where they could be used for commercial

6. U. S. Patents No. 980,021, *Loaded Phantom Circuit*, G. A. Campbell and T. Shaw, and No. 981,015, *Phantomed Loaded Circuit*, T. Shaw.

service in extending the range of telephone transmission, the adaptation of the lines to the requirements of repeater operation was secondary in importance only to the development of satisfactory repeater elements and circuits for associating the repeater elements with the lines[7].

TABLE VII
FIRST STANDARD LOADING COILS FOR PHANTOM WORKING

Type Line	Inductance (Henrys)	Coil Code No.	Type Circuit	Average Resistance-Ohms D-C.	Average Resistance-Ohms 1000 cycles	Overall Dimensions Diameter (In.)	Overall Dimensions Height (In.)

	0.155	530	Phantom	4.4	11.9	5.9	2.9
	0.175	514	Side	5.4	14.4	4.6	2.4
	0.106	513	Phantom	2.7	7.1	5.9	2.9

NOTE. The resistance data apply to circuits of a complete phantom group: *i. e.*, the side circuit data include effects of the phantom coils, and phantom circuit data include effects of the side circuit coils. Effective resistance values correspond to line current of 0.002 ampere.

Early Work—Reduction of Line Irregularities. Commercial telephony, requiring two-way transmission, imposes severe balance requirements on repeater circuits over the entire band of frequencies which the repeater is designed to transmit. The solution of this problem required (a) the construction of lines having extremely regular impedance features, (b) the development of balancing networks[8] capable of accurately simulating the impedance characteristics of the improved lines throughout the working frequency range, and (c) the use of electric wave filters[9] in the repeater sets which cut off somewhat below the cutoff frequency of the loading.

In loaded lines, the uniformity requirements call for the loading coils to have very closely the same inductance value and to be capable of resisting the magnetizing effects of abnormal service conditions; also the sections of line between loading coils should have closely the same value of capacitance.

Transcontinental Lines—High Stability Loading Coils. The inauguration of commercial transcontinental telephone service over the New York-San Francisco line in January 1915 marked the first commercial application of the general improvements in regularity of line construction, including the use of an improved type of loading coil having a very high degree of magnetic stability.

In the development of the improved coils the requirement laid down was that the inductance to speech currents should not be changed more than about two per cent when a magnetizing current of two amperes was passed through any of its line windings. In the older types of coils, this severe magnetization condition caused a drop of about 30 per cent in the coil inductance: The new design which was adopted involved the use of two air gaps at opposite points in the (iron wire) cores of loading coils[10], suitable clamping means being provided to hold the coil halves in proper alignment. Data regarding these coils are given in Table VIII. To assist in getting a maximum degree of line regularity, these coils were adjusted in the factory to meet ± 1 per cent inductance limits. In the older types of coils ± 5 per cent deviations had been allowed.

In the case of coarse gage cable circuits, installed prior to the advent of repeaters, the new requirements were met by the design of an air-gap type of wire core coil on which data are given in Table VIII.

TABLE VIII

Resistance data apply to side circuits and phantom circuits of complete phantom groups. Effective resistance values are for 0.002 ampere line current.

Compressed Powdered Iron Core Loading Coils. The use of telephone repeaters made it possible in new cable installations to supersede the No. 10 and No. 13 A. w. g. gage conductors by No. 16 and No. 19 A. w. g. conductors. This development greatly increased the need for an efficient and stable loading coil of lower cost than the air-gap wire core coil. To meet this need there was standardized early in 1916 a new magnetic material, compressed powdered iron, which has been of the utmost value in loading coil design[11]. Briefly,

the method of production consists of grinding electrolytically deposited iron to the desired fineness, insulating the particles, and finally compressing these insulated particles in steel dies at very high pressures. The compressed powdered iron core by virtue of its very numerous, though extremely small distributed air gaps, has a very high degree of magnetic stability[12].

These coils are used in the loading systems listed in Tables V and X.

effective permeability of about 60. Further developments resulted in the standardization of an improved grade of compressed powdered iron core having a permeability of 35. Coils having this new material 60-permeability compressed core coils were restricted to interoffice trunks and to short toll cables operated without superposed telegraph. Data on these two types of coils are given in Table IX.

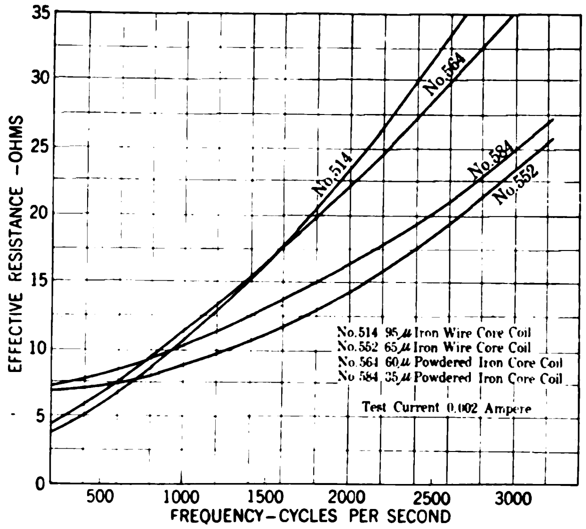

Fig. 7—Effective Resistance-Frequency Characteristics Toll Cable Loading Coils

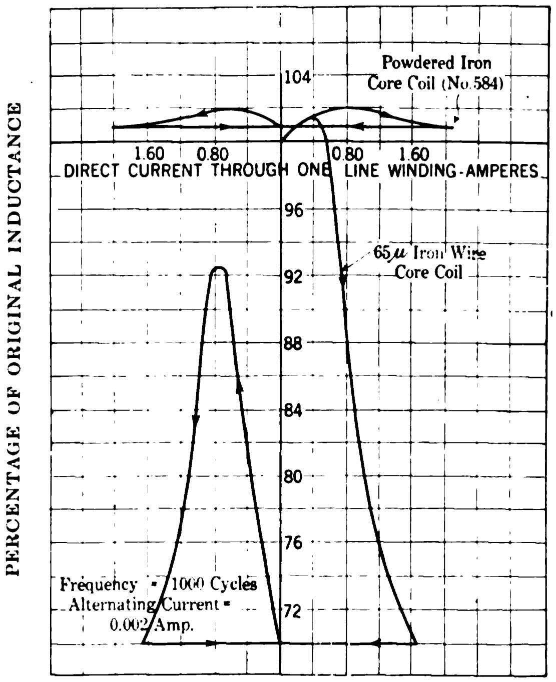

Fig. 8—Residual Magnetization Characteristics of Compressed Powdered Iron Core and Iron Wire Core Loading Coils

The effective resistance-frequency characteristics of 60-permeability and 35-permeability compressed powdered iron core coils and the older 95-permeability and 65-permeability wire core coils having the same inductance (0.175 henry) and the same overall size, are given in Fig. 7. The large improvement as to freedom from residual magnetization effects afforded by the 35-

12. *Magnetic Properties of Compressed Powdered Iron*, B. Speed and G. W. Elmen, Trans. A. I. E. E., Vol. XL, 1921.

permeability powdered iron core, compared with the old standard 65-permeability wire core coil is evident from the curves of Fig. 8.

The value of the compressed powdered iron core coil in the modern loading art has been recognized to the extent of its adoption as an international standard for repeatered circuits[13].

New requirements for Cable Loading Systems. The completion of the development of a satisfactory commercial type of telephone repeater marked the beginning of a long period of experimental work for the purpose of determining the commercial possibilities of the use of repeaters over long cable circuits. During these experiments, as the lengths were increased, echo and velocity distortion effects became increasingly troublesome, and it became apparent that improved loading would be necessary in order to realize the full possibilities of the use of repeaters.

Echoes. Echoes are due to unbalance currents, *i. e.*, to reflections of electrical energy at points of impedance irregularity in the circuits. When the circuit is so long that the time of transmission from the point of reflection to the disturbed subscriber station is appreciable, there will be echo effects, unless the losses in the circuit are so large as to cause the reflected energy to become inappreciably small.

Velocity Distortion. The velocity distortion in long lines is noticeable during the building up and dying down periods, when it manifests itself as transient distortion. The duration of transient distortion depends, among other factors, upon the length of the line, the nominal velocity, and the cut-off frequency of the loading. A substantial reduction in the transient distortion has been obtained in the new standard loading systems by raising the cutoff frequency as well as the velocity of the loading.

Experimental data regarding transient distortion is given in an Institute paper[14] by Mr. A. B. Clark and the results of theoretical studies are given in an earlier Institute paper[15] by Mr. J. R. Carson.

Characteristics of Improved Cable Loading Systems. The principal electrical features of the H-44-25 and H-174-63 phantom group loading systems which have been developed primarily for use on long repeatered cables are given in Table X, which also includes corresponding details of the older standard loading systems developed for non-repeatered cables. Typical attenuation-frequency curves of the old and new loading systems are given in Fig. 10.

Table XI lists the combinations of loading, conductor gage and type of repeater circuit which are used in meeting the wide range of commercial requirements. The position of the facility item in the table indicates the sequence of transmission excellence, item (*i*) being the highest grade facility in this respect.

For a further discussion of the use of repeatered loaded lines the reader is referred to recent papers presented before the Institute by Mr. J. J. Pilliod[16] and Mr. H. S. Osborne[17].

Attenuation—Frequency Distortion. In addition to their improved velocity and cut-off frequency characteristics, the H-44-25 and H-174-63 loading systems

TABLE X

LOADING SYSTEMS—SMALL GAGE REPEATERED TOLL CABLES

Item	(*a*) Loading System	Circuit	(*b*) Coil Code No.	Nominal Impedance (Ohms)	Nominal Cut-off Frequency (Cycles)	Transmission Velocity Miles-per Second	(*c*) Attenuation Loss TU per Mile at 1000 Cycles 19 A. w. g.	16 A. w. g.	(*d*) Maximum Geographical Length (Miles)
(1)	H- 44-25	Side	590	800	5600	19000	0.48	0.25	5000
(2)	"	Phantom	591	450	5900	20000	0.40	0.21	5000
(3)	H-174-63	Side	584	1550	2800	10000	0.28	0.16	500
(4)	"	Phantom	587	750	3700	13000	0.28	0.16	1500

(8)	"	Phantom	581	1150	2400	8000	0.20	0.12	250

Notes: (*a*) Nominal coil spacing is 6000 feet in cable having a capacitance of 0.062 μf per/mile in the side circuits and 0.100 μf per mile in the phantom circuit.

(*b*) The loading coil data are given in Table IX.

(*c*) These attenuation values apply at 55 deg. fahr. Under extreme temperature conditions, the actual attenuation may be approximately 12 per cent larger or smaller, due principally to changes in conductor resistance with temperature. In long repeatered cable circuits these variations of attenuation with temperature require special corrective treatment by means of automatic transmission regulators.

(*d*) The length limitations are set by transient distortion effects; echo currents may limit circuit lengths to lower values, depending on the grade of balance of the lines and the permissible over-all loss.

Fig. 11 give corresponding curves for non-repeatered cables (No. 19 A. w. g.) having the same types of loading as before, in each case the length being chosen so that the circuits have a 10 *T U* loss at 1000 cycles.

In very long lines, the line losses, even with the best grade of loading, may cause sufficient distortion to require the use of correcting devices. The improvement obtainable by suitably designed repeaters is illustrated by an appropriately marked dot-dash curve in Fig. 11 which gives the attenuation-frequency characteristic of a 500-mile H-44-S circuit (No. 19 A. w. g.) as set up for commercial service.

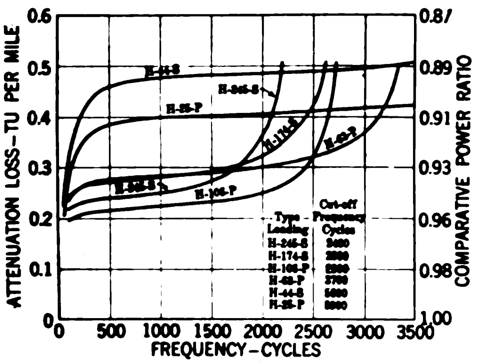

Fig. 10—Attenuation-Frequency Characteristics of Toll Cable Loading

In connection with the foregoing discussion, it is important to keep in mind the fact that coil loading substantially improves the attenuation and substantially reduces the frequency distortion at a cost which is much lower than the cost of the additional repeaters and distortion corrective networks which would be required to give the same grade of transmission without using loading.

Cost considerations make it desirable to use aerial cable in the long toll cable installations. On the main trunk cables an aerial fixture capable of supporting 4 or 6 large coil pots is required. A fixture of this type is illustrated in Fig. 12.

Long Repeatered Open-Wire Lines. The use of improved types of repeaters now makes it economical to secure better transmission results in long open-wire circuits without loading, than can be secured in loaded repeatered lines. This is because in non-loaded open-wire lines the distributed inductance is sufficiently large to keep the frequency distortion low; also, the transmission velocity is relatively very high.

Loading is now being removed from the important lines and it is expected that new applications of loading will generally be limited to isolated cases of short lines,

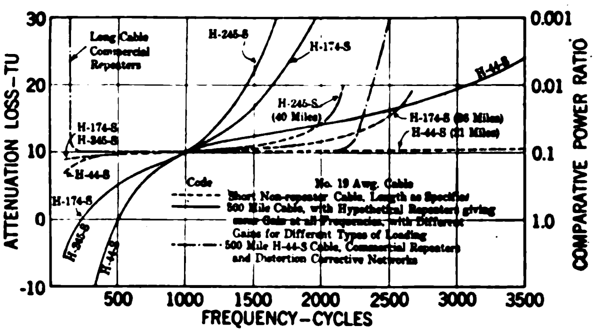

Fig. 11—Attenuation-Frequency Characteristics of Short and Long Loaded Toll Cable Circuits having a Net Attenuation Loss of 10 *TU* at 1000 Cycles

where carrier telephone or telegraph systems are not contemplated or where the maintenance and operating conditions are unfavorable to the use of telephone repeaters.

Loading for Incidental Cables in Open-wire Lines

In the loading application discussed in the other sections, the primary purpose of the loading is to reduce

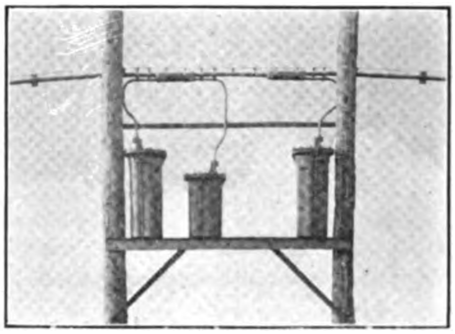

Fig. 12—Installation of Aerial Toll Cable Loading on 4-Case "H" Fixture

line attenuation losses and frequency distortion effects. In the case of incidental pieces of cable in open-wire lines, however, the primary function of the loading is to give the inserted cable approximately the same characteristic impedance as the open-wire line, in order to minimize junction reflection effects. This particular type of loading is becoming increasingly important because of the rapidly increasing use of repeaters on open-wire lines.

In incidental cables associated with loaded open-wire

lines, the primary requirements for matching impedance, are that the nominal impedance ($\sqrt{L/C}$) and the cut-off frequency of the loaded cable and of the loaded line should be closely the same. The E-248-154 phantom group cable-loading system listed in Table XII meets these general requirements.

The loading problem for an incidental cable in a non-loaded open-wire line requires an impedance match between a smooth line and a lumpy line, and therefore involves some degree of compromise, because

TABLE XII
TYPICAL LOADING SYSTEMS FOR TOLL ENTRANCE AND INTERMEDIATE CABLES

Loading System Designation	Type Circuit	Coil Inductance Henrys	Coil Spacing Miles	Nominal Impedance Ohms	Cut-off Frequency Cycles	Attenuation Loss TU per Mile at 1000 Cycles	
E-28-16	Side	0.028	1.09	650	7200	0.15	(13 A.w.g.)
	Phantom	0.016	1.09	400	7800	0.13	
CE-4.1-12.8	Side	0.0041	0.176	600	45000	0.22	(13 A.w.g.)
	Phantom	0.0128	1.09	400	8500	0.19

	Phantom	0.025	1.66	400	4900	0.24	
E-248-154	Side	0.250	1.09	1950	2400	0.081	(13 A.w.g)
	Phantom	0.155	1.09	1200	2500	0.070	

NOTE. Cable capacitance is assumed to be 0.062 μf per mile for side circuits, and 0.100 μf per mile for phantoms.

of the dependence of the impedance of a coil-loaded cable upon the loading termination, as illustrated in Fig. 3. At frequencies above approximately 500

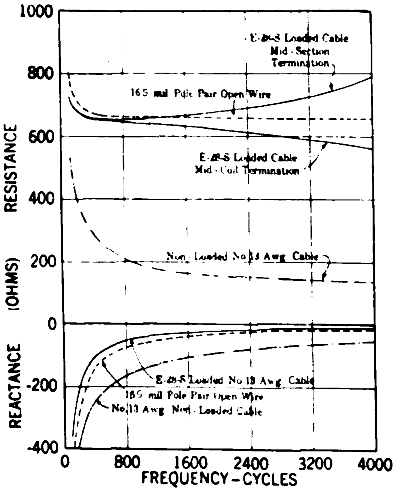

FIG. 14—TYPICAL IMPEDANCE-FREQUENCY CHARACTERISTICS OF LOADED AND NON-LOADED ENTRANCE CABLE AND NON-LOADED OPEN-WIRE LINE

cycles, the impedance of the non-loaded open-wire line is practically a non-inductive resistance, constant with frequency. On the other hand, with mid-section and mid-coil terminations, the impedance of the coil-loaded cable is substantially that of a non-inductive resistance as illustrated in Fig. 3. The higher the cut-off frequency of the loading, the more closely do these resistance-frequency curves approach the flat resistance-frequency curve of the non-loaded line, over the range of frequencies which the telephone repeaters are designed to transmit; provided, of course, that the cable loading also has the same nominal impedance as the non-loaded line. For plant simplicity and economy, it is desirable to use the same coil spacing in the different types of incidental cable-loading systems.

The above general considerations have led to the standardization of the E-28-16 loading system for use on cables associated with non-loaded open-wire lines. General data regarding this system are given in Table XII, and impedance frequency curves are given in Fig. 14.

Carrier-Frequency Loading. Special types of loading typified by the "CE-4.1-12.8" system in Table XII have been developed for use on incidental cables in non-loaded open-wire lines on which carrier telephone or carrier telegraph systems are superposed. The

TABLE XIII
CARRIER FREQUENCY LOADING

Frequency Kilocycles	Attenuation Loss - TU per Mile (13 A. w. g. Cable) Non-Loaded	C-4.1 Loading	Resistance-Ohms per Carrier Loading Coil
1	0.49	0.23	1.5
5	0.78	0.27	1.6
10	0.90	0.33	1.9
20	1.14	0.52	4.1
30	1.37	0.90	8.1

present standard carrier telephone systems operate up to frequencies of the order of 30,000 cycles.[18] Data regarding attenuation losses in a No. 13 A. w. g. cable with and without carrier loading are given in Table XIII.

The high-frequency loading is used only on the side circuits, since at the present time it is not customary to operate carrier telephone systems over phantom circuits. Carrier operation imposed upon the carrier-frequency coils involves new requirements as regards freedom from intermodulation between channels, and low energy losses at carrier frequencies. These requirements were met by using toroidal-type wood core coils with finely stranded copper windings. Typical resistance-frequency data are included in Table XIII.

CROSS-TALK

One of the greatest practical difficulties which has been encountered in extending the commercial range of long distance telephone service is that of keeping at a tolerably low value the speech overhearing known as cross-talk which occurs between adjacent telephone circuits whenever there is an appreciable amount of

18. "Carrier Current Telephony and Telegraphy," Colpitts and Blackwell, TRANS. A. I. E. E., Vol. XL, 1921, p. 205.

electromagnetic or electrostatic coupling between them. This difficulty is in part due to the fact that as the length of the line increases, there are more and more opportunities for unbalances in the lines and in the associated apparatus. Moreover, the repeaters amplify the cross-talk as well as the speech transmission. From the service standpoint, however, it is necessary that the cross-talk in the very long lines should be within the limits set for the shorter lines.

The problem of keeping cross-talk low between the individual circuits of a phantom group is by far the most difficult phase of the general cross-talk problem in long repeatered cables. The unbalances in the cable quads are reduced to small values by exercising great care in manufacture and by selective splicing at the time of installation. By design, the loading coils are substantially free from inherent unbalances, and great care is exercised in manufacture to realize the benefits of this inherent symmetry of design.

When repeaters came into general use it was found necessary to obtain much more refined adjustments than those previously made; so further improvements were worked out in several manufacturing processes. As a result of these various improvements, the unbalances in the loading coils are now only about one-fourth of the earlier values. For instance, the average cross-talk in the coils used for H-44-25 loading is now about 20 millionths of the disturbing current. This corresponds to an attenuation of about 95 *T U*.

To assist in visualizing the real achievement which this minute value of phantom-to-side cross-talk represents, Table XIV gives information regarding the cross-talk effects of different elementary types of unbalance in H-44-25 loading coils:

TABLE XIV
CROSSTALK DUE TO UNBALANCE IN H-44-25 LOADING COILS

Type of Unbalance	Amount of Cross-talk
1 ohm resistance	400 millionths (68 TU)
1 micro-henry inductance	2.5 " (112 TU)
1 turn of winding	280 " (71 TU)
1 micro-microfarad capacitance	0.94 " (121 TU)

The cross-talk current caused by electromagnetic unbalances flows around the two ends of the disturbed circuit in series. On the other hand, the cross-talk current caused by electrostatic unbalances divides and flows from its point of origin in opposite directions around the two ends of the circuit in parallel. Consequently, when electrostatic and electromagnetic cross-talk currents are in phase at one end of the circuit, they tend to be in phase opposition at the other end of the circuit. The special cross-talk adjustments are made in such a way as to obtain the maximum benefit from the phase-opposition effects at the particular end of the circuit where these reductions are more important, *viz.*, at the "near-end" for two-wire circuits and at the "far end" for four-wire circuits.

Unbalances in loaded circuits which contribute to noise due to induction from power transmission and distribution circuits are similar in nature to those contributing to cross-talk. The precautions which are taken in the design, manufacture, and installation of loaded circuits to reduce unbalances have the effect, therefore, of reducing both cross-talk and noise.

Telegraphy Over Loaded Telephone Circuits

After the introduction of loading it was desirable to continue superposing d-c. ground return telegraph currents on telephone circuits. As the lengths of the loaded circuits increased, the interaction between the telegraph and telephone currents which has been designated in an Institute paper[19] as "flutter," was aggravated and serious distortion of speech resulted. Considerable study was given to the flutter problem, and important improvements were made by changes in the design of the magnetic circuit and improved core materials.

The increasing use of long repeatered toll cables brought about a need for further reduction in flutter distortion which was met by the development of a metallic telegraph system in which the amplitude of telegraph currents is of the same order of magnitude as the telephone current[20].

More recently the development of a voice-frequency carrier telegraph system[21] providing ten or more independent channels over a loaded four-wire cable circuit has made it economical to concentrate a large part of the telegraph service over the long repeated cables on a special group of wires which is not used simultaneously for telephone purposes.

Recent Improvements in Loading for Exchange Area Cables

The first important change in the exchange area loading standards occurred about 1916, when compressed powdered-iron core coils came into general use in place of the old standard wire core coils. In the period 1922-24, the use of new types of fine wire cables had reached a point which required changes in the loading systems and accordingly, a new series of improved loading systems having a considerably higher cut-off frequency, were developed.

Cable Development. Notable advances have been made in the art of cable manufacture during the last decade, including the standardization of 450-pair No. 19 A. w. g. cable, 900-pair No. 22 A. w. g. cable, and 1200-pair No. 24 A. w. g. cable, all within standard full-

sized sheaths (2 5/8 in. outside diameter). The 50 per cent increase in the number of circuits over the older cable designs was accompanied by a substantial increase in the mutual capacitance.

The use of the old standard loading systems on the new types of cables would have resulted in an objectionable impairment of quality, due to the reduction of the cut-off frequency resulting from the increased cable capacitance. Also the types of loading coils available were more expensive than could be justified for permanent standards on the low cost fine wire cables.

Determination of New Cut-off Frequency Standard. A coil design cost-balance study was taken up as one phase of a general transmission-cost study of exchange area transmission, which also included a theoretical investigation of cut-off frequency standards.

It was found that an increase in the cut-off frequency of exchange area loading up to about 3000 cycles could be justified; the increased costs for materially higher cut-off frequencies would have been unduly large in proportion to the resultant improvement in transmission.

New Standard Loading System. The new standard exchange area loading systems make as much use as is practicable of the old standard coil spacings and inductance values, in order to minimize the expense of rearranging the existing loading to conform to the new standards, and at the same time make full use of the large number of available loading vaults and manholes. General data regarding these new standards are given in Table XV.

TABLE XV
NEW LOADING STANDARDS FOR EXCHANGE AREA TRUNKS

Loading Designation	Coil Spacing Feet	Coil Code Nos.	Approx. Cut-off Frequency Cycles: High Capacitance Cable	Approx. Cut-off Frequency Cycles: Low Capacitance Cable
M-88	9000	602	2900	3200
H-135	6000	603	2800	3200
H-175	6000	574	——	2800
D-175	4500	574	2900	3200

NOTE. High capacitance cable has approximately 0.083 μ per mile. Low capacitance cable has approximately 0.066 μf per mile.

The M-88 system is especially suitable for the shorter lengths of fine wire trunk cables which will constitute the bulk of the exchange area trunk mileage. In longer trunks, the other more expensive loading systems find their field of service. The H-175 system is limited to low capacitance cables because of the lower cut-off effects on high capacitance cables, but has considerable commercial importance because of the large number of low capacitance cables now in the plant.

Table XVI gives some general transmission data on typical exchange area trunks using the new loading systems, including also non-loaded trunks. Attenuation-frequency curves of some of these trunks are given in Fig. 15, which includes also a dotted line curve for the old standard medium loading when used on 0.065 m. f., No. 19 A. w. g. cable.

In the application of the new standard loading systems, the same standards of over-all attenuation loss are adhered to, as in the older loading systems.

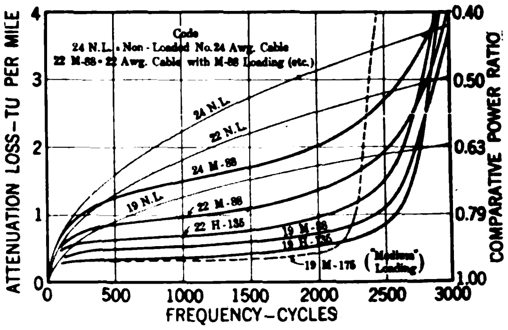

FIG. 15—ATTENUATION-FREQUENCY CHARACTERISTICS OF TYPICAL EXCHANGE AREA LOADED AND NON-LOADED CABLES

In consequence, there is an appreciable improvement in the intelligibility of transmission, due to the ability of the new loading systems to transmit efficiently a range of high-frequency voice over-tones which were suppressed by the old standard 2300-cycle cut-off systems. Along with this improvement in service,

TABLE XVI
TRANSMISSION CHARACTERISTICS OF TYPICAL EXCHANGE AREA TRUNKS

Cable Conductor A. w. g.	Capacitance μf./Mile	System	Coil Code No.	Cut-off Frequency Cycles	Circuit Impedance Ohms	Attenuation Loss TU per Mile

22	0.083	" "	—	—	570	1.8
24	0.079	M-88	602	2900	900	1.48
22	0.083	M-88	602	2900	990	0.96
22	0.083	H-135	603	2800	1300	0.68
19	0.085	Non-loaded	—	—	400	1.27
22	0.083	D-175	574	2900	1690	0.53
19	0.083	M-88	602	2800	860	0.51
19	0.085	H-135	603	2800	1280	0.38
19	0.066	H-175	574	2800	1640	0.29
19	0.085	D-175	574	2800	1680	0.30
16	0.066	M-88	602	3200	960	0.24
16	0.066	H-135	603	3200	1420	0.20
16	0.066	H-175	574	2800	1640	0.17

NOTE. The impedance and attenuation figures hold at 1000 cycles. Impedance values for loaded circuits assume mid-section termination.

the new loading systems substantially reduce the plant cost, partly due to the economies which result from the extension of the transmission range of the new types of fine wire cables and partly because of the use of materially less expensive types of loading coils.

Loading Coils and Cases. Table XVII gives general data for the coils used in the new exchange area loading systems.

The standardization of the small size Nos. 602 and 603 loading coils has made it possible to design containing cases and assembly methods which permit

larger numbers of coils—up to 300—to be enclosed in the loading cases. Fig. 17 illustrates the operation of assembling the loading coils, previously spliced to the cable stub, into a 300-coil pot. The use of these larger potting capacities will be of considerable value in reducing the space congestion in the loading vaults in "downtown" districts of the larger metropolitan areas.

TABLE XVII

COILS FOR LOADING EXCHANGE AREA CABLES

Coil Code No.	Inductance (Henrys)	Core Permeability	Resistance-Ohms D-C.	Resistance-Ohms 1000 Cycles	Over-all Dimensions Inches Diameter	Over-all Dimensions Inches Height
602	0.088	35	8.9	10.5	3.6	1.3
603	0.135	35	12.8	14.1	3.6	1.3
574	0.175	60	4.6	10.6	4.5	2.1

Effective resistance values are for a line current of 0.001 ampere.

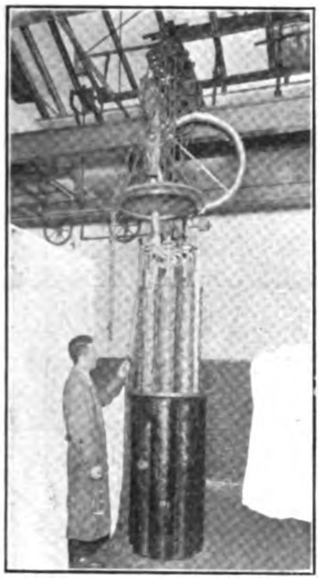

FIG. 17—ASSEMBLY OF 300-COIL CASE

Lowering loading coils into case after coil spindles have been mounted on frame and coil terminals spliced to stub cable conductors

In general, exchange area loading is installed in underground vaults or manholes. Fig. 18 shows a typical installation in a "double-deck" vault in New York City.

EXTENT OF COMMERCIAL APPLICATION

Conservative estimates set the total number of loading coils in service in the Bell System, as of January 1, 1926, at 1,250,000. These coils provide loading for about 1,600,000 miles of cable circuits and 250,000 miles of open-wire. In round numbers, 500,000 coils are installed on non-quadded local area trunk cables and 700,000 in toll entrance and toll cables (the bulk of these being quadded cables). Nearly two-thirds of the total number of coils have compressed-iron powder cores, all of these being installed on cable circuits. Recent estimates of the loading coil requirements for the next five years indicate an annual demand which will double the total number of loading coils in service by about 1930.

CONCLUSION

It will be appreciated from the foregoing account that the invention of coil loading was the beginning of an era of intensive development which has been marked by enormous advances in the design of telephone transmission lines, nor is there any slackening of the inventional or development activity devoted to this subject.

In conclusion, it may be of interest to note what the development and use of loading has meant to the telephone using public from an economic standpoint. Leaving out of consideration altogether loading on long toll cables—where the interdependence of repeaters and loading is such that it is impracticable to assign to each its share of the savings—and taking into consideration only the loading of interoffice trunks and toll open-wire circuits, it has been estimated that the larger wires which would have been required to give the present grade of transmission if loading had not been available, together with the heavier pole lines and additional underground ducts, would have entailed an additional investment in Bell System telephone plant of over $100,000,000.

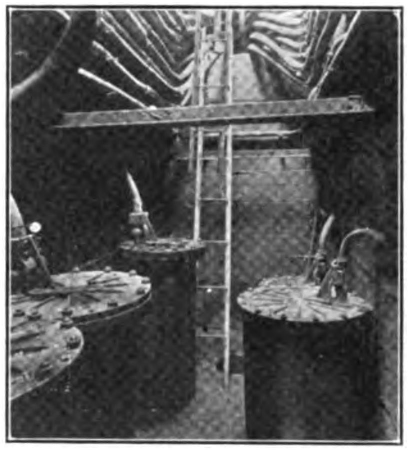

FIG. 18—UNDERGROUND CABLE LOADING COIL INSTALLATION IN METROPOLITAN AREA. DOUBLE-DECK VAULT HAVING ULTIMATE CAPACITY OF 14 LARGE COIL CASES

METHODS OF HARDENING HIGH-SPEED ROUGHING TOOLS

Since the discovery some 20 years ago of the benefits derived by subjecting certain chormium-tungsten or so-called high-speed steels to exceedingly high temperatures in hardening, much discussion has centered upon the best procedure and equipment for this heat treatment.

Some roughing lathe tool tests were recently made at the Bureau of Standards to determine whether or not such claims were justified. It was found that comparable performance was obtained when tools were raised to approximately equal temperatures for equal times in hardening.

No-Load Copper Eddy-Current Losses

BY THOMAS SPOONER[1]

Member, A. I. E. E.

***Synopsis.**—One of the factors which is sometimes responsible for very considerable losses in rotating machines is that of eddy-current losses in the copper conductors resulting from slot leakage flux produced by the main flux. These losses occur at no-load as well as under load and should not be confused with the copper losses resulting from the slot leakage flux produced by the load current. These no-load copper losses occur in salient pole machines, both d-c. and a-c., and in induction motors.*

This paper is an attempt to remove the calculation of no-load copper eddy-losses from the field of empiricism where it has previously been and to place it on a firm theoretical foundation. Test results are presented which show that the theoretical formulas which have been developed are correct.

Some of the consequences of this analysis are rather unexpected where the frequencies are sufficiently high to produce large skin effect. For instance, laminating the copper may produce increased or decreased losses, depending upon the conditions.

* * * * *

Introduction

The design of electrical apparatus is becoming so standardized, and the efficiencies so high, that further improvements in performance will probably come largely through attention to details which previously have been considered of somewhat minor importance. This paper considers one of these details which has, perhaps, not received as much attention as its importance under certain conditions would warrant.

When a copper conductor in the slot of a rotating machine carries alternating current there are produced slot leakage fluxes which may induce sufficiently large eddy currents in the conductor copper to result in very appreciably increased losses. This type of loss has been quite adequately dealt with by Field, Gilman, and others. The type of copper eddy-current loss with which this paper deals has a different origin and is the result of slot leakage fluxes caused by the main flux. These losses are often nearly as large at no-load as at full load, and are of importance in connection with both salient pole machines and induction motors.

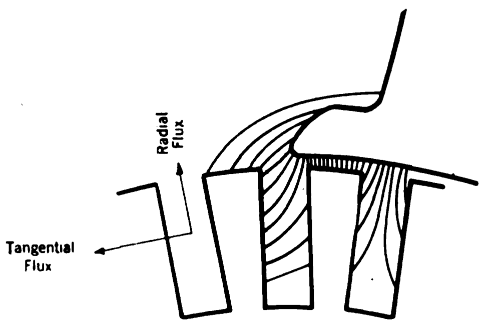

Fig. 1—Slot Leakage for Salient Pole Machine

Cause and Nature of Losses

Fig. 1 illustrates the nature of the slot-leakage flux for a salient pole machine. As a slot comes out from under the pole tip there is a rapid decrease in the radial component of slot-leakage flux and a rapid generation and then dying out of the tangential component of slot-leakage flux as shown by Fig. 2, which is from test data obtained on a small d-c. railway motor with unsymmetrical pole tips. It will be seen that the radial leakage flux consists chiefly of the fundamental, while

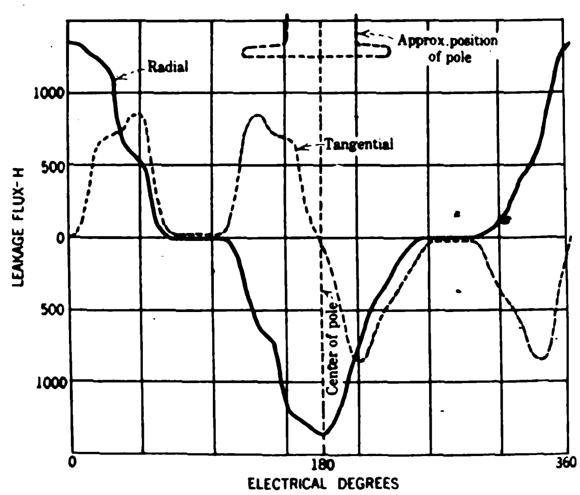

Fig. 2—Slot Leakage Fluxes for D-C. Railway Motor

the tangential flux has a larger third harmonic than it has fundamental. Some of the other harmonics for the tangential flux are also quite large. These results are typical.

Fig. 3 shows the nature of the slot-leakage fluxes for an induction motor. It will be seen that there are

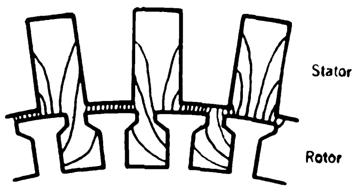

Fig. 3—Slot Leakage for Induction Motor

leakage fluxes in the rotor slots having both radial and tangential components. The radial components pulsate in amplitude but do not change sign while under a given pole. The tangential components reverse in sign twice during the interval required for a rotor tooth to

1. Research Engineer, Westinghouse Electric & Mfg. Co.

Presented at the Midwinter Convention of the A. I. E. E., New York, N. Y., February 8-11, 1926.

pass over a distance equal to one stator slot pitch. The slot-leakage fluxes, both tangential and radial, therefore, have a frequency equal to the number of stator teeth per pair of poles, multiplied by the rotor frequency, the latter frequency being in general nearly equal to the applied fundamental frequency. These leakage fluxes are small in magnitude but high in frequency and are often of importance. In the ordinary construction, consisting of nearly closed rotor slots, the pulsations of leakage flux in the stator slots are usually negligible.

These slot-leakage fluxes are appreciable only when the teeth begin to saturate. In salient pole machines, tooth inductions of the order of 120 kilolines per sq. in. are necessary before noticeable eddy losses in the copper conductors begin to be produced. For induction motors the tooth inductions must reach about 70 kilolines per sq. in. before copper eddy losses of noticeable magnitude appear. The reason for the lower inductions for the induction motors is because of the much higher frequency of the slot-leakage fluxes. In the case of the salient pole machines the radial fluxes produce very little loss as a rule, because the frequency is so low and because the copper is usually narrow tangentially. The tangential leakage fluxes, however, may produce very considerable losses, and consequently heating, due to their higher-frequency components and the fact that the radial dimensions of the copper are usually fairly large. In the induction motor, both components of the leakage flux may be quite effective in producing copper eddy losses.

Calculation of Copper Eddy Losses

A number of formulas have been devised for calculating this type of loss, but they all contain empirical constants and all neglect certain essential factors. For instance, one of Mr. Lamme's formulas,[2] which was designed for use with large salient pole machines and was very satisfactory for the particular conditions, gave calculated losses which were from 6 to 10 times the true values when applied to a certain small railway motor. The formulas which will be proposed in this paper are based on fundamental considerations only and were devised without reference to any test data.

If the copper bars in a slot are narrow radially or the frequency is sufficiently low, the no-load eddy losses in the copper may be calculated by the following simple formula:

$$W_e = \frac{\pi^2}{6} \times \frac{W^2}{\rho} f^2 H^2 10^{-7} \qquad (1)$$

(See list of symbols below.)

If, however, the bars are wide (this refers to radial width when considering tangential slot leakage flux) or the frequency high, the above formula will no longer apply, due to the fact that the eddy currents in the copper produce a damping effect on the flux, thus making the losses less than would otherwise occur. This is the well-known skin effect. Under these conditions the flux in the region of the center of the bars is damped out. (See Fig. 4.) The eddy currents are greater in magnitude as the bottom and top of the bars are approached and there are no appreciable currents in the center; that is, if the center portions of the copper were removed there would be no change in the eddy losses.

Some time ago we developed the following formula for calculating eddy losses under the conditions of appreciable skin effect:

$$W_e = \frac{\pi^2 f^2 H^2}{m^3 \rho W 10^7} \; \frac{\sinh m W - \sin m W}{\cosh m W + \cos m W} \qquad (2)$$

The method of developing this formula was similar to that used by Latour for his formulas dealing with losses in laminated steel at radio frequencies.[3] Dr. J. Slepian assisted in the development of this formula. For no skin effect the results are identical with those obtained

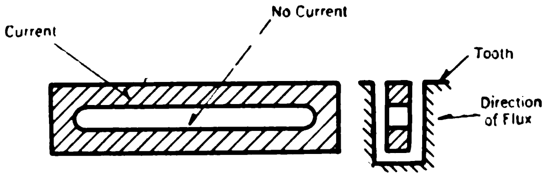

Fig. 4—Copper Eddy-Current Losses, Illustrating Skin Effect

by the simple formula (1). In the use of either formula, the eddy losses have to be calculated for each frequency; namely, for salient pole machines the magnitude of the various important harmonics has to be determined by test and analysis or estimated in some way from the machine design and the losses corresponding to each harmonic calculated as if the others did not exist. The sum is the total eddy loss. In the case of the induction motor, it is generally satisfactory to consider only the pulsating frequency corresponding to the number of stator teeth, without considering harmonics.

When it was attempted to apply formula (2) to actual machines it was found that in many cases the experimental and calculated results did not correspond as closely as was expected. In order to determine whether the discrepancies were due to inaccuracies in the formula or to the neglect of certain factors having to do with the conditions in the actual machines, the fundamental tests which are about to be described were made.

3. Notes on Losses in Sheet Steel at Radio Frequencies; Marius Latour. Inst. of Radio Engineers *Journal*, February 1919, p. 61.

Test Methods and Apparatus

The method of test was suggested by a similar method devised by Churcher.[4] As shown by Fig. 5, a laminated yoke was constructed having pole pieces which were adjustable to the right and left in order that the air-gap could be varied. This air-gap was about 6 inches by 2 inches and its width between pole pieces could be adjusted from 7/8 inch to 0. The yoke was provided with windings as shown. High-frequency current up to 1000 cycles was obtained from a generator through an ammeter A. In general, the samples consisted of two copper bars as indicated. Two small holes were drilled near the center of one of the bars about 1/8 inch apart and thermocouple wires of copper and advance

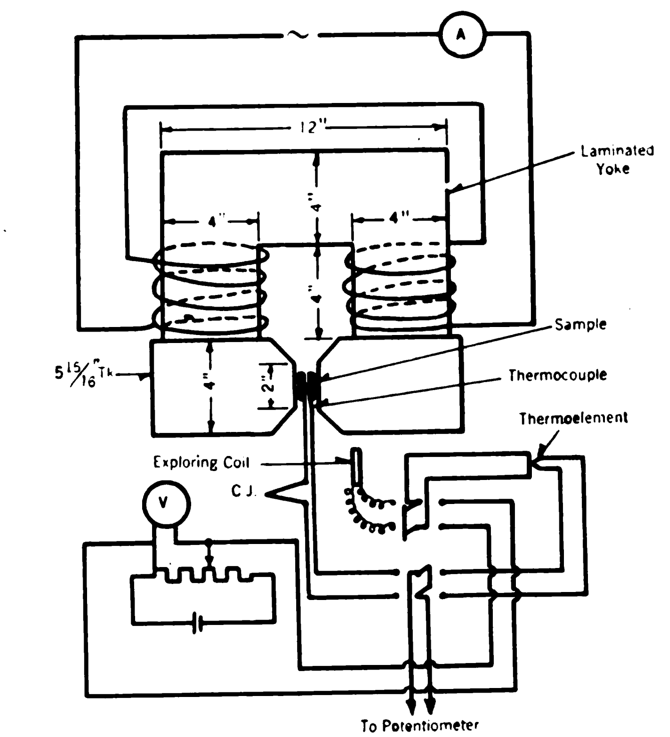

Fig. 5—Copper Eddy-Current Losses—Diagram of Connections

soldered into the holes. The bars were separated from each other by a small distance and the couple wires were insulated from the bars except at the junction. The wires were brought out from between the bars at one end, thus keeping a considerable length adjacent to the copper in order to prevent loss of heat at the junction. An exploring coil wound on a rectangular bakelite form was provided for determining the flux density in the air-gap. The coil was approximately 6 inches by 1/2 inch and had 21 turns.

The method of test was as follows: The air-gap was adjusted to the desired width and alternating-current of the desired frequency applied to the field winding. Assuming a sine wave of flux in the air-gap, the voltage which would be induced in the exploring coil for the desired induction was calculated. The voltmeter V was then adjusted to this value, the current element of a sensitive vacuum thermo couple was connected to the terminals of the voltmeter by a suitable manipulation of the switches and the terminals of the thermo-element connected to a Wolff potentiometer. The e. m. f. of the thermo-element was then read. Next the exploring coil was placed in the air-gap, the switches manipulated, and the magnetizing current adjusted by control of the high-frequency generator field until the thermo-element produced the same reading on the potentiometer as was obtained from the d-c. voltage. This gave the required induction in the air-gap. The thermo couple attached to the sample was then connected to the potentiometer. The cold junction of this couple was placed in a thermos bottle which was at any convenient temperature, preferably near room temperature. A copper sample which should be at or below the temperature in the air-gap was then placed in the gap, the high-frequency current switched on, and the ammeter adjusted to its original value without the sample. The potentiometer was set to some convenient reading corresponding to a value slightly above room temperature. Due to the eddy losses in the sample the temperature immediately began to rise. When this temperature corresponded to the setting on the potentiometer, the potentiometer galvanometer went through O and a stop-watch was started. The potentiometer was then set to a higher reading. When the galvanometer went through O again the watch was stopped and another started by means of a simple arrangement of levers. This was repeated five or six times in order to obtain sufficient data for plotting a curve between millivolts and time interval. By extrapolating back to the millivolts corresponding to the temperature at the air-gap (with corrections for cold junction temperature) the rate of temperature rise in seconds (ΔT_i) for a given change in millivolts could be obtained. Knowing the millivolts per degree for the thermo couple at this temperature, the rate of temperature rise per degree could be calculated.

The eddy losses were calculated as follows, assuming a temperature of 25 deg. cent.,

$$W = Q \frac{d\,t\,e}{d\,t} \text{ watts}$$

$$Q = 4.186 \times .0917 \times G$$

where

Q is the thermal capacity of the conductor in watt-sec. per deg. cent.,

G is the weight of conductor in grams

$\frac{d\,t\,e}{d\,t}$ is the rate of temperature rise, namely the deg. cent. rise per sec. on the assumption that there is no heat lost or gained from the outside. Since the rate

4. The Measurement of Temperature in a Rotating Armature by Means of Thermocouples, B. G. Churcher. *Journal of Sci. Inst. V. I.*, July, 1924, p. 310

was determined corresponding to the temperature of the surroundings, there was no correction for dissipated heat; 4.186 is the thermal capacity of water in joules per gram calorie; 0.0917 is the specific heat of copper with reference to water at 25 deg. cent.

Test Results

In order to keep the rate of temperature rise down to a reasonable value, very low air-gap inductions were used; namely, of the order of a few hundred gausses. Under these conditions there was no appreciable heating of the yoke material and the reluctance of the iron path was practically negligible. Therefore, for a given air-gap the induction was practically constant for a definite exciting current for a wide range of frequencies as shown by test results not given here.

If the sample had appreciable skin effect, the counter magnetomotive force of the eddy currents in the copper had the effect of increasing the reluctance of the air-gap. Therefore, when the copper was introduced into the gap

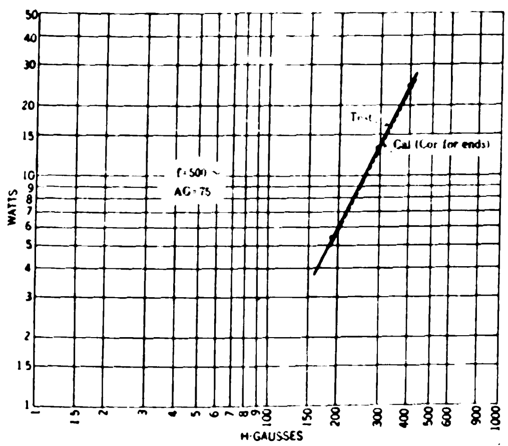

Fig. 6—Copper Eddy-Current Losses, Two Bars ¾-in. x ¼-in. x 10-in.

the exciting current increased. It was found that if the exploring coil was placed in the air-gap just above the copper, the magnetizing current had to be brought back to its original value in order to bring the air flux in the gap above the copper back to its original value. Provided the current was so adjusted, it was immaterial whether the m. m. f. was measured with or without the sample in position.

In order to obtain data for the purpose of determining the validity of our method of calculating eddy losses, a number of copper samples were tested under various conditions. Fig. 6 shows the results of the first set of tests. Two bars ¼ by ¾ by 10 inches long were placed in the air-gap (0.75 inches) with the shortest dimension parallel to the flux. Losses were determined at 500 cycles for three values of m. m. f., namely, 190, 291 and 395 gausses, and the results plotted on double log paper. The m. m. f. and flux density, namely, gilberts per centimeter and gausses are used interchangeably since in the c. g. s. system they are identical. For comparison, values as calculated by formula 2 are shown. The test and calculated values check very well with respect to magnitude and slope. As indicated by theory, the losses increased as H^2.

The next set of tests are shown by Fig. 7. The results are for the same set of bars but in this case H was held

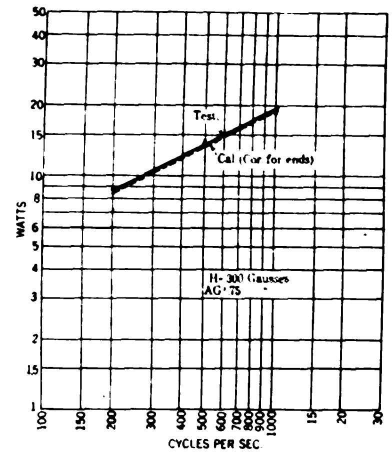

Fig. 7—Copper Eddy-Current Losses, Two Bars ¾-in. x ¼-In. x 10-In.

at 300 gausses and the frequency changed from 200 to 1000 cycles. Under the particular conditions of frequency and copper dimensions there was large skin effect. According to theory, the losses should, in this

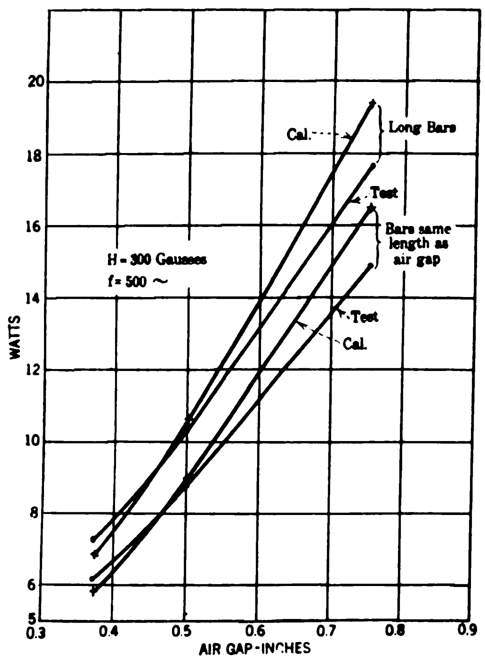

Fig. 8—Copper Eddy-Current Losses, Two Bars 1/8-In. x 1.0-In. x 10-In., Two Bars 1/8-In. x 1.0-In. x 5 15/16-In.

case, increase as the square root of the frequency. It will be seen that within the experimental errors this was the case.

It will be noted that in the case of Figs. 6 and 7 the copper bars were considerably longer than the length of the air-gap. This is, of course, the condition in rotating

machines. In several cases tests were made with long bars and then the bars were cut off to the length of the air-gap and again tested in order to determine the amount of the end effect. It was found in all cases tried that if the effective length of the bar for the long bars was taken as equal to the air-gap length plus a length equal to the vertical dimension of each bar (see Fig. 5) the end effects would be very closely compensated for. This explains the notation in Figs. 6 and 7 ("corrected for ends").

Fig. 8 shows the relation between air-gap and loss for an H of 300 gausses and a frequency of 500 cycles. In this case there were two bars, $\frac{1}{8}$ by 1 by 10 inches. The results are also given for the same bars cut to the length of the air-gap. The test results follow the theoretical values within reasonable limits, the test values being a little less for the large air-gaps and a little

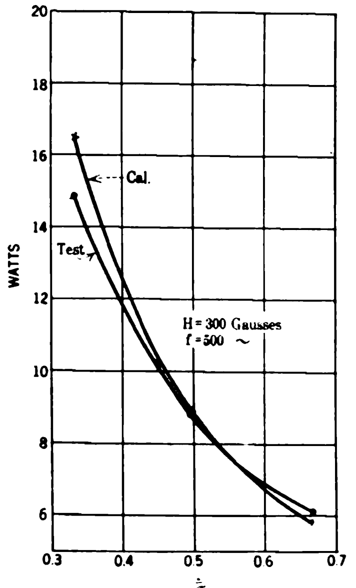

FIG. 9—COPPER EDDY-CURRENT LOSSES, TWO BARS 1/8-IN. X 1/10-IN. X 5 15/16-IN.

greater for the small air-gaps. Obviously for solid copper in the gap (100 per cent space factor) the gap would be 0.25 inch.

Fig. 9 shows the same data for the short bars only plotted against t/σ (ratio of copper thickness to gap width or the space factor of the copper).

Table I gives some further comparisons between test and calculated results and includes the data of the previously mentioned curves. In most cases the average test values have been converted to a standard m. m. f. of $H = 300$ according to the square law, although the tests were made at other m. m. fs. The dimensions in the table for the copper are approximate values. The actual values were used for the calculations.

Discussion of Results

Except in two or three cases the test and calculated results are as close as could be reasonably expected. When the space factor is low and the bars are wide, there is a tendency for the calculated results to be high. In the case of the four bars side by side with the larger cross sectional dimension vertical there is a tendency for the calculated values to be low. We may say that for all practical purposes and under the conditions of these experiments the calculated values are sufficiently

reliable. All ranges have been covered from the simple case of no skin effect (formula **1**) to the case of large skin effect. Moreover multiple bars have been used and the results check practically as well as for a single pair of bars.

Unfortunately, in the case of rotating machines, the conditions are not as simple as in the ideal case. In

the present tests the effective width of air-gap is the actual width of gap. In the case of rotating machines the corresponding actual width of slot is not the effective width which has to be used in the formula. By eferring to Fig. 8 or 9, for instance, it will be seen that the larger the width of the gap the greater the copper loss for a given air-leakage flux, (assuming the conductors have large skin effect). For no skin effect the losses are independent of the gap width. Now in the case of rotating machine teeth the teeth themselves are saturated to some extent, at least, or there would be no appreciable slot leakage fluxes. This means that their permeability is low and that an appreciable m. m. f. is required to force the flux through them. Again the applied m. m. f. which causes the leakage flux to pass across the slot may partly, at least, traverse a second slot and the machine air-gap. This means that due to the higher actual m. m. f. applied over that necessary to cause flux to cross the particular slot in question, the eddy currents in the copper would not be as effective in damping out the flux as would otherwise be the case, and therefore the losses are higher. This means that the value of σ in formula (**2**) should be increased by some more or less uncertain amount.

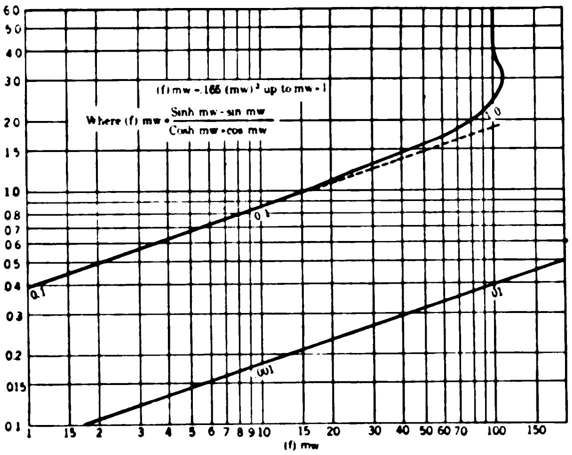

FIG. 10—COPPER EDDY-CURRENT LOSSES, SHOWING HYPERBOLIC FUNCTION IN EXPONENTIAL FORM

In the majority of machines which we have tested, σ should be multiplied by 1.5 on the average, but in some cases it has to be much higher than this and in a few cases lower. Before it would be possible to accurately predict the necessary corrections for all types of machines, much more experimental data must be obtained.

CHARACTERISTICS AND CALCULATION OF EDDY LOSSES

An analysis of the test results and of formulas (**1**) and (**2**) reveal some interesting relations. If the function

$$\frac{\sinh m\,W - \sin m\,W}{\cosh m\,W + \cos m\,W}$$

is plotted against $m\,W$ on double log paper, there is obtained the relation shown by Fig. 10. It will be seen that for any value of $m\,W$ up to 1, the function increases approximately as the cube of $m\,W$. Above 2 the function is nearly equal to 1. The reason that the function reduces to 1 is that for large values the sinh and cosh terms are practically equal and increase very rapidly in magnitude, thus making the sine and cosine values negligible. When this function reduces to 1, the losses are obtained from the first part of formula (**2**), namely

$$W_e = \frac{\pi^2 f^2 H^2}{m^3 \rho\, W\, 10^7} \qquad (3)$$

In order to further simplify this expression, assume that $\rho = 1.8$ by 10^3 (1.8 microhm centimeters corresponds to 31 deg. cent).

$$W_e = 1.688 \times 10^{-7} \frac{f^{1/2} H^2}{\left(\frac{t}{\sigma}\right)^{\frac{3}{2}} W} \qquad (4)$$

(when $\rho = 1.8$ by 10^3)

The variations of the watts per cu. cm. with frequency, air-gap, space factor and radial width of copper are now evident. It has been shown experimentally that these relations are approximately correct. They apply only when the product $m\,W$ exceeds 2 (large skin effect). Using this relation, care must be taken to note the causes of the changes in $\frac{t}{\rho}$ and W and the fact that this formula gives the watts per cu. cm. and not the total watts. If t/σ is changed by increasing the width of gap (or slot for the machine), but with the copper the same, the total eddy losses will vary as $(t/\sigma)^{-3/2}$ for a given H as shown by the formula or as $\sigma^{3/2}$ (slot width). Now if t/σ is altered by changing the total thickness of copper the weight is also changed and therefore the total loss varies at $(t/\sigma)^{-1/2}$, namely, for a given slot the total loss varies inversely as the square root of the tangential copper thickness per slot.

Again suppose the width of the copper (W) is changed by increasing the width of the individual bars then, since an increase in width means an increased total volume of copper, the losses are independent of the copper width W (for large skin effect). This is obvious from the fact that there are no eddy currents near the middle of the bars (see Fig. 4). If, however, W is changed by laminating but keeping the total weight of copper the same, the total losses are, as shown by the formula, inversely proportional to W; but as the laminating is continued the skin effect is reduced and soon the losses begin to decrease as the square of W or according to formula (**1**). Fig. 11 illustrates such a condition. It will be seen that for the particular conditions the losses increase rapidly with increasing lamination and then decrease. These are calculated values but test results would show the same thing. The main point is that laminating may increase or

diminish copper eddy losses depending upon the conditions.

Now in using this formula, m should first be calculated as shown above, namely $m = 2\pi\sqrt{\frac{f\,t}{\sigma\,\rho}}$ or $m = 0.148\sqrt{f \times \frac{t}{\sigma}}$ for $\rho = 1.8 \times 10^3$. Then if the product $m\,W$ is less than I, formula (**1**) or some modification may be used, or if desired formula (**2**) may be used. If $m\,W$ is over 2, or for accurate work over 4, formulas (**3**) or (**4**) may be used. For intermediate values use formula (**2**) or use formulas (**3**) or (**4**) and multiply by $(f)\ m\,W$ as obtained from Fig. 10. Assuming

$\rho = 1.8 \times 10^3$ formula (**1**) becomes

$$W_e = 0.915 \times 10^{-10} f^2 W^2 H^2 \quad (\text{when } \rho = 1.8 \times 10^3) \qquad (5)$$

and may be used for approximate results up to values of $m\,W$ of 1.5.

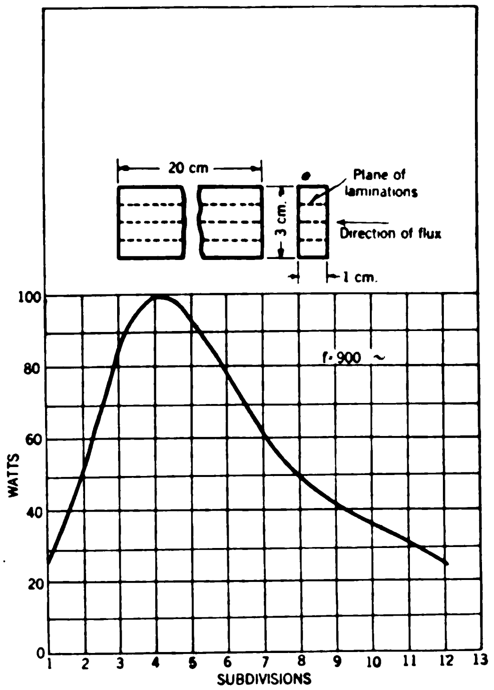

Fig. 11—Copper Eddy-Current Losses—Variation of Loss due to Laminating

Application of Formulas

As pointed out above, formula (**2**) or its modifications will, in general, give results which are of the right order of magnitude if σ the slot width is increased by 50 per cent before using in the formula. This method of calculation may be used for salient pole machines. In this case the tangential slot-leakage curves must be analyzed into their harmonics and the copper losses calculated for each harmonic. For low frequencies, formula (**1**) will usually apply, but for the higher harmonics some form of formula (**2**) must be used. In the case of wound-rotor induction motors the no-load copper eddy losses may be calculated by assuming a single frequency corresponding to the tooth-pulsation frequency. The radial as well as the tangential slot-leakage fluxes may be of importance in this case.

As a first approximation if test data are not available the radial slot-leakage flux may be assumed to be equal to the m. m. f. necessary to magnetize the teeth adjacent to the slot and the tangential slot-leakage flux to the difference in m. m. f. between the two adjacent teeth. Of course, tooth taper introduces complications but this can readily be taken care of approximately. As pointed out, the chief difficulty is in determining the total effective m. m. f. where skin effect is large. In calculating the total loss the volume of copper is that in the slot plus an amount corresponding to an added length of copper equal to W.

Summary of Formulas

For $m\,W$ less than 1 (approximately correct to 1.5).

$$W_e = \frac{\pi^2}{6} \times \frac{W^2}{\rho} f^2 H^2 10^{-7} \qquad (1)$$

$$W_e = 0.915 \times 10^{-10} f^2 W^2 H^2 \quad (\text{when } \rho = 1.8 \times 10^3) \qquad (5)$$

For $m\,W$ between 1 and 4.

$$W_e = \frac{\pi^2 f^2 H^2}{m^3\,\rho\,W\,10^7}\ \frac{\sinh m\,W - \sin m\,W}{\cosh m\,W + \cos m\,W} \qquad (2)$$

For $m\,W$ greater than 4 (Approximately correct for $m\,W$ above 2).

$$W_e = \frac{\pi^2 f^2 H^2}{m^3\,\rho\,W\,10^7} \qquad (3)$$

$$W_e = 1.688 \times 10^{-7} \frac{f^{1/2} H^2}{\left(\frac{t}{\sigma}\right)^{\frac{3}{2}} W} \quad (\text{when } \rho = 1.8 \times 10^3) \qquad (4)$$

The above formulas, when ρ is included in the constant, are based on copper at 31 deg. cent. For copper at 65 deg. cent. ρ should be taken as 2.0×10^3 instead of 1.8×10^3. For copper or aluminum alloys, use the formulas with ρ.

For cool machines on no-load test, formulas (**4**) or (**5**) will, in general, be satisfactory. For hot machines they may be modified, as indicated above but this refinement will usually be found unnecessary due to other much larger uncertainties. Formula (**4**) is to be used when $m\,W$ is greater than 2 and formula (**5**) when $m\,W$ is less than 1.5. For intermediate values of $m\,W$ corrections according to Fig. 10 may be applied or Fig. 10 may serve merely to indicate the possible errors which will result by neglecting this correction.

The above assumes that the effective slot-leakage flux is the tangential component. For the radial component, copper dimensions at right angles must be used.

Symbols

$$m = 2\pi\sqrt{\frac{ft}{\rho}}$$

$$= 0.148 f \times \frac{t}{\sigma} \quad (\text{when } \rho = 1.8 \times 10^3)$$

W_ϵ = eddy loss in watts per cu. cm. of bar material.
f = cycles per second.
t = thickness of copper bar (tangential) multiplied by the number of bars side by side in a slot.
σ = slot width
ρ = resistivity of bar material in abohms (equals microhm – cm. by 10^3).
W = radial width of individual bars in cm.
H = slot leakage m. m. f. in gilberts per cm. or slot leakage flux in gausses (no bars).

Conclusions

The above-described experiments indicate that the formulas for no-load copper eddy-current losses due to the slot-leakage fluxes are correct to within 10 or 15 per cent for all of the conditions tried which cover a wide range. In the case of rotating machines, however, we have the saturation of the teeth, other gap reluctances and other factors which make it very difficult sometimes to estimate accurately the total m. m. f. applied to the slot-leakage magnetic circuit. In general, fairly reliable corrections may be made by adding 50 per cent to the slot width. When skin effect is small no appreciable errors will result since the loss is independent of the gap reluctance, assuming a given leakage flux. This analysis gives the following interesting relations.

For small skin effect, $m\,W$ less than 1, (low frequency or narrow bars) the eddy losses for a unit volume of copper vary as $f^2\,W^2$. For large skin effect, $m\,W$ greater than 2, (high frequency or wide bars) the eddy losses for a unit volume of copper vary as $f^{1/2}$, $(t/\sigma)^{-3/2}$, W^{-1} and H^2. For variations in total copper eddy current losses consideration must be given, as previously mentioned, to the way in which t/σ and W are varied.

In the case of salient pole machines the wave shape of the slot leakage fluxes must be analyzed or the components estimated and the losses calculated for each component frequency. In the case of induction motors the tooth-pulsation frequency is to be used.

Even though these formulas often can not be used directly without considerable labor, they should serve a very useful purpose in indicating quickly the result of changing the laminating of the copper and changing the slots. The interesting fact has been pointed out that in some cases increased laminating of the copper may increase the losses, while in others it decreases them.

Summary

Check tests are presented, showing that our theoretical formulas for calculating no-load copper eddy-current losses are reliable provided all of the conditions are known. The actual application to rotating machines may yield erroneous results due to difficulties in estimating the total reluctance of the flux-leakage paths. These formulas in their present form should be useful for calculating roughly the amount of no-load copper eddy losses in salient pole machines and induction motors. They should also be useful for determining the effect of changes in the section of the individual copper bars in the slot with reference to eddy losses. Later it is hoped that more reliable and simpler methods for using these formulas will be devised.

AUTOMOBILE HEADLIGHTING

For several years the bureau has been working with technical societies, State officials, and others in the attempt to improve the headlighting of automobiles. This question has been revived more actively than ever during the past year as the result of discussions following the National Conference on Street and Highway Safety called by Secretary Hoover in December, 1924. In order to obtain more complete and reliable information regarding the actual status of headlighting and the possibility of its improvement, a joint committee representing the Society of Automotive Engineers and the Illuminating Engineering Society has recently been formed and is attempting to lay out a program of research on this subject. Members of the bureau's staff have been appointed as representatives of both societies on this committee. The bureau has also been called on for technical advice in connection with the requirements of the proposed uniform vehicle code which is to be considered at the next meeting of the national conference. In this connection the bureau has advocated the general plan of making laws and regulations as simple as possible and depending upon education of motor-car manufacturers and users for the betterment of actual road conditions. With this in view, Circular No. 276, Motor Vehicle Lighting, was issued some time ago and has found extensive circulation. This circular is not available for free distribution, but can be obtained from the Superintendent of Documents, Government Printing Office, Washington, D. C., for 20 cents per copy.

Electrification of Paper-Making Machines

BY STEPHEN A. STAEGE[1]

Fellow, A. I. E. E.

***Synopsis.**—The ever increasing speeds of paper making machines has made necessary the replacement of the inadequate mechanical drive with electrical sectional drive, and the perfection acquired in modern electrical sectional paper machine drive has made possible unlimited paper speed in so far as the drive and control is concerned.*

Not only is electrical sectional drive necessary for high speed machines but it is highly economical for even the slowest speed machines on account of the saving in power over mechanical drive, the great saving in maintenance, and the greater precision with which the section speeds can be maintained thereby greatly reducing the number of paper breaks and increasing production.

This paper outlines the several trends of development in an historical sketch of progress in the art up to the present time, devoting special attention to a unique system of direct current drive in which the section driving motors through a differential electrical field control means, cause the several section driving motors to operate in synchronous relation at any desired relative speed values, which speed relations are at the same time adjustable at the will of the operator.

INTRODUCTION

THE production of a continuous sheet of paper, 12 to 18 ft. wide and 250 to 1000 mi. long without a break on the machine—a paper speed of 1000 ft. per min. or more—has been made possible by electrical sectional paper-machine drive and control.

The frail web of paper, about three mils thick, passes without support from section to section of the machine, passing between heavy press rolls, tons in weight; threading around 30 or 40 steam-heated dryer rolls; through the eight or ten-roll calender stack weighing a hundred tons or more, and onto the reel.

In the travel of the sheet through the paper machine from the "wire" where it is formed to the calender where it is finished, the sheet usually increases in length from five to ten per cent. Therefore, the sheet is actually traveling faster when it leaves the machine than at the beginning of its travel. In fact, there is usually a progressive increase in the speed of travel of the sheet as it goes from section to section, on account of its stretch.

There are two principal types of paper-making machines, known as cylinder machines and Fourdrinier Machines. The fundamental differences are in the wet or forming-end of the machine.

The Fourdrinier Machine is the type always used for high speed, in making newsprint and kraft paper and in the manufacture of book, writing and the higher grade papers.

The Cylinder machine is inherently a slower speed type and is used chiefly in the manufacture of box and container board, roofing felt, and the heavier sheets.

The paper-making machine in its usual form consists of a number of sections independently driven but which must be maintained in operation at the proper speed relations to each other. Not only must the proper speed relation be maintained between sections, but these speed relations must be adjustable at the will of the operator so that they can be adapted to the requirements of the sheet of paper. These may change slightly in elongation or shrinkage on account of variations in the condition of the stock, temperature, atmospheric conditions and a number of other factors; the stretch or shrinkage of the sheet depending largely upon the thickness, quality, condition of stock and amount of pressure used in removing the water.

In addition to the requirement of adjustability of speed between sections to take care of variations in elongation and shrinkage, it is essential that the entire machine be adjustable in speed over a wide range, without disturbing the speed relation of the several sections.

The speed range of a newsprint machine may be 600 to 1200 ft. per min.; a kraft machine, 200 to 800 ft; a book machine, 100 to 600 ft.; a specialty Fourdrinier Machine, perhaps 100 to 800 ft.: While a cylinder machine sometimes has a speed range as great as 35 to 350 ft.; although a more common range for this type of machine is 50 to 200 ft. of paper per min.

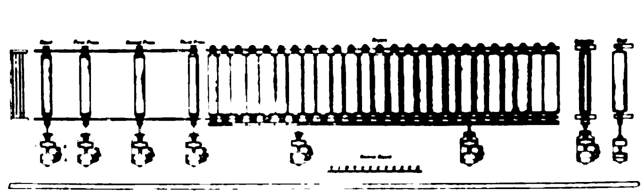

FIG. 1—TYPICAL SECTIONAL PAPER-MACHINE DRIVE

A typical high-speed Fourdrinier Machine (Fig. 1) usually consists of eight sections; a "wire" or couch section, three press sections, two dryer sections, one calender section and a reel section. Fig. 2 shows schematically a side elevation of such a machine.

The first section of the Fourdrinier Machine, known as the "Fourdrinier," "wire" or "couch" section, has a revolving wire screen of fine mesh. This Fourdrinier wire, in the form of a wide belt the width of the machine, operates around two rolls, the one at the extreme end of the machine called the breast roll and the one at the other end of the "wire," the "couch" roll. This is the driven member of the section, the breast roll being rotated as a pulley by the wire. The wire may be from

1. Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa.

To be presented at the Regional Meeting of District No. 1 to be held at Cleveland, Ohio, March 18-19, 1926.

50 ft. to more than 100 ft. long, depending upon the size and speed of the machine; and the span of the wire is kept from sagging by a large number of small "table" rolls located close together under the top pass of the wire, which carries the stock.

The press sections consist of pairs of heavy rolls, weighted with compounding levers, and between the upper and lower rolls of which the sheet, on its felt conveyor, passes. The lower roll is driven and the upper roll rotates by contact traction with the lower roll.

In the dryer sections some 15 or 20 dryer rolls or drums, four, five or six feet in diameter are nested in a group and geared together by intermeshing spur gears. There are usually two dryer sections which may be independently driven and regulated or may be geared together.

The calender stack consists usually of eight or ten chilled-steel rolls accurately ground and polished and driven by the bottom roll, all of the upper rolls being rotated by surface contact friction.

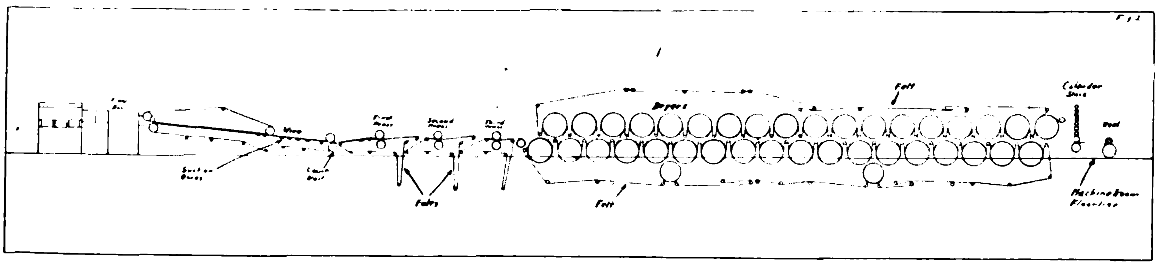
A "uniform speed" reel is commonly used, the spool and roll of paper being rotated by the traction of surface contact with the reel drum.

From the "couch" the sheet, though very wet and frail, spans a distance of a foot or more until it reaches a felt conveyor by means of which it is carried through the first press, then to the second and third presses, on independent felts and across another unsupported span to the dryer sections. Dryer felts hold the sheet in contact with the hot dryer drums as it is threaded through the nest of dryers. From the dryers, the sheet passes across a span of more than five ft. to the calender stack and thence to the reel.

Passing from the "wire" at the "couch," additional water is removed by pressure in going through the presses, and most of the remaining water is removed by heat in the steam-heated dryer sections.

The function of the paper machine is to reduce the stock mixture, evenly distributing the fibers in proper relation, fabricating them into a continuous web, removing the excess water by filtration, pressure and heat and giving the final sheet of paper the required finish, and to wind it into rolls of convenient size.

In putting the sheet on the machine, it is put over at the full normal operating speed by means of air jets, in the case of high speed machines at least, by



SIDE ELEVATION OF FOURDRINIER PAPER MACHINE SHOWING THE COURSE OF THE SHEET FROM THE WIRE TO THE REEL.

FIG. 2—SIDE ELEVATION OF FOURDRINIER PAPER MACHINE SHOWING THE COURSE OF THE SHEET FROM THE WIRE TO THE REEL

A very large percentage of the paper of today is made from wood pulp, the individual fibers having been reduced or separated by mechanical or chemical processes and mixed in a suitable proportion of water.

In the manufacture of paper, the raw material passes through several processes and refinements before it goes to the paper-making machine in a fluid mass consisting of approximately $\frac{1}{2}$ of 1 per cent stock and $99\frac{1}{2}$ per cent water.

The Fourdrinier section of the machine receives the stock from a flow box, located above the breast roll, from which it flows by gravity onto the revolving fine wire screen from a thin submerged orifice extending the width of the machine and located just above the "wire."

When the stock flows onto the "wire," much of the water immediately passes through by gravity, and further along its travel a considerable part of the remaining water is drawn through the wire from the stock film on its surface by a number of flat suction boxes located below it in which 10 to 15 inches of vacuum is maintained.

means of which a leader strip is detached from the "wire" at the couch and blown across the gap to the felt conveyor of the first press. At each section the air jet is used to transfer the narrow leader strip to the succeeding section. As soon as the leader strip has been started the sheet is widened by tapering out at the "wire" until it is the full width of the machine.

In cylinder machines, the design and functioning of the various parts is much the same as that of the Fourdrinier machine, except that the forming of the sheet is done on cylinder moulds instead of on a Fourdrinier wire. A machine may have several cylinder moulds consisting of skeleton drums covered with fine wire screen. These revolve slowly in vats containing paper stock and each cylinder mould contributes a thin layer of stock to the final heavy sheet. A revolving felt conveyor picks up the stock from the cylinder mould drums, carries the laminated stock film between small presses where it is pressed into a homogeneous fabric and part of the water is removed, and thence carries it through the first press from which the operation is similar to that of a Fourdrinier machine.

Early Methods of Drive

For many years, the paper-making machines were mechanically driven by variable speed engines or motors or other variable speed means to take care of the speed range required, and the individual sections were driven from a line shaft through gears and belt or rope drive with cone pulleys, so that by shifting the belt on the cone pulleys, the required relative speed between sections could be obtained. Such systems were unusually subject to belt slippage on account of the poor belt contact on the cone pulley surfaces and on account of the vertical-belt drives which were usually necessary; they required mechanical clutches or belt slackening and tightening devices so that any section could be stopped and started independently of the rest of the machine; and they suffered from more than the usual troubles and limitations to which mechanical drives are subject.

As early as 1905 to 1910 several installations of electrical sectional paper machine drives, but without automatic speed regulation, were made in an effort to overcome the serious shortcomings of mechanical drive, but most of these early installations because of poor speed regulation were unsuccessful—only two of these early sectional drives remaining in service. It was only through infinite care in the design and in field adjusting of the equipment that operation was made possible, and that only by frequent hand adjustments of rheostats by the operators.

The search for a more satisfactory type of drive was a difficult one. For obvious reasons, synchronous motors could not meet the various requirements of paper-machine drives and the best inherent characteristics of d-c. motors did not provide speed regulation of sufficient precision over the speed range required, and were furthermore subject to the effects of changes in resistance due to temperature changes resulting in variations in speed. An automatic speed regulator was, therefore, sought to control the speed of the d-c. driving motors for each of the sections. It was immediately apparent that none of the usual types of speed governors or regulators would suffice, inasmuch as speed control within limits of the order of $^1/_{10}$ of 1 per cent or closer was necessary for satisfactory performance. The differential principle was, therefore, finally made use of as this offered possibilities of practically infinite precision of speed control of integrated values. To correct for a tendency of the motor to change in speed, a small change in angular displacement of the motor armature with respect to a time cycle is necessary, but the motor can be made to operate for an indefinite period without gaining or losing in rev. per min.

Paper machines sectionally driven by d-c. motors and controlled by regulators of the electrical differential type have now been in operation in this country and Canada for some six years. The details of the mechanism by means of which differential speed regulation with field control is obtained, has gone through a process of evolution whereby the apparatus required has been greatly reduced and simplified and improved in quickness of response.

First Automatically Regulated Electrical Sectional Drive

In the first electrical sectionally-driven paper machine in this country to be automatically controlled by the electrical differential regulator principle, a master unit was provided to which the speed of the sections was referred (Fig. 3). The master consisted of a motor-driven a-c. generator, and from each section of the paper machine there was also driven, through a control speed changer, a small a-c. generator. Connected electrically between the master generator and the section generator was a wound rotor induction motor, the stator being connected to the master generator and the rotor to the section a-c. generator. When connected in the proper phase relation so that the magnetic field in the rotor would rotate in the same direction as the magnetic field in the stator and at the same speed, no rotational

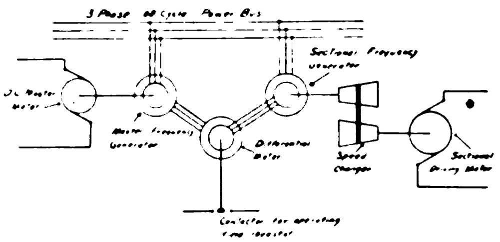


Fig. 3—Schematic Diagram of First Electrical Differential Speed Control System

movement of the rotor would take place. If, however, the d-c. section driving motor for any reason should slow down or speed up, this would, of course, cause a corresponding change in the frequency of the generator driven from the section motor, from that of the master, and the rotor of the induction motor would then rotate in the one direction or the other, depending upon the higher frequency and at a rate of speed corresponding to the difference in frequency of the two generators between which it was connected. This constituted an electrical differential.

A motor-operated field rheostat was provided in the shunt-field circuit of each of the section driving motors (Fig. 4) and through movement of the differential element, the wound rotor induction motor, contact means were provided so that a rotational movement of a very small fraction of a revolution in either direction would serve to make a contact thereby operating the rheostat in one direction or the other as required to correct the speed of the section-driving motor. This relay method of operating the field rheostat was used instead of coupling the rheostat directly to the shaft of the differential motor so as to relieve the differential control system

of the necessity of developing sufficient torque to turn the rheostat which would detract from its sensitivity; and also to obtain characteristics whereby the travel of the rheostat arm was not a direct function of the movement of the rotor of the differentially connected induction motor. Reaction magnets were provided to prevent overtravel of the rheostat and hunting.

This system was quite effective but had its limitations particularly in range of control, speed of regulation and tendency to oscillate on account of the definite step characteristic of the rheostat which obviously could not be made to meet the exact requirements of the speed necessary for the section motor.

The master and section a-c. generators used were of the induction frequency changer type which appeared to be the most desirable for this service. Standard wound rotor induction motors were used and were driven at a speed usually about 50 per cent below synchronous speed so that when excited from a 60-cycle source, the output frequency of these frequency changer generators would be about 30 cycles at the maximum paper speed and this frequency would increase as the paper speed decreased. The use of this type of generator avoided the necessity of d-c. excitation and provided all of the characteristics required and any variations in the frequency of the exciting source would have no affect upon the regulation as they would take place equally on both sides of the differential.

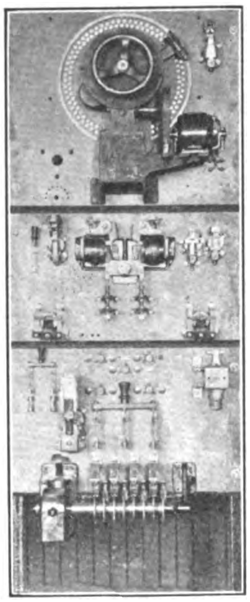

FIG. 4—DIFFERENTIAL RELAY AND MOTOR-OPERATED FIELD RHEOSTAT OF FIRST ELECTRICAL DIFFERENTIAL SPEED CONTROL SYSTEM OF SECTIONAL DRIVE

With this arrangement it will be seen that when the speed of the section motor is correct, the secondary frequency of the master and section frequency changer or generator is the same and no rotation of the induction motor connected between the two frequency changers takes place. If, however, a change in angular displacement of the section frequency changer takes place with respect to the master, a similar movement takes place in the rotor of the wound rotor motor and through the rheostat indirectly actuated by this movement, resistance is cut in or out of the shunt-field circuit of the section driving motor, thereby tending to maintain its speed at the required value.

Following shortly after the installation in 1919 of the first control system of the type described, two other systems of sectional paper-machine drive and control also came into use; one known as a "synchronous motor tie-in" system, and the other as an "interlock" system.

SYNCHRONOUS MOTOR TIE-IN SYSTEM

The "synchronous motor tie-in" system (Fig. 5), instead of automatically regulating the d-c. section motor field strength to maintain the proper speed relation between sections, employed a synchronous motor for each paper-machine section, of about one-fifth the capacity of the main d-c. section driving motor. The synchronous motors were driven from the main d-c. section driving motors through a spur-gear reduction and a pair of cone pulleys with belt drive. The synchronous motors were d-c. excited and had their three-phase armature circuits connected to a common or "dead" bus, as it was called. This "dead" bus was not connected to any other source of power.

The object of the synchronous motors was to hold the speeds of the d-c. section driving motors at their proper speed relation, as determined by the position of the belts on the cone pulleys.

In the event of a tendency of the d-c. section driving motor to change in speed, due to a load change or temperature change, the synchronous motor was called upon to carry the increase or decrease in the load of the section, or the load thrown off or taken on by the d-c. section motor due to a temperature change and corresponding change in field resistance. This was necessary in order that the synchronous motor might remain in synchronism with the "dead" bus and the other synchronous motors.

It will be observed that with this arrangement, any load taken by the section synchronous motor as a motor must be furnished by the other synchronous motors connected to the "dead" bus, as generators; and any load furnished by the section synchronous motor in question, as a generator, must be absorbed by the other synchronous motors. Since any change in load, or tendency to change in speed, on the part of a d-c. section driving motor creates a call indirectly upon each of the other section motors to carry or absorb the change in the section in question, the entire paper machine would tend to change in speed, to a degree depending upon the droop of the load speed characteristic curves of the d-c. section driving motors and in an amount, compared to the section tending to change, approximately inversely proportional to the number of sections.

It will, also, be observed that the d-c. section driving motor in question could only change in speed with respect to the frequency of the "dead" bus, or the equivalent approximate mean paper speed, an amount permitted by the change in belt stretch, creep and slip on the cone pulleys, resulting from the change in load being transmitted, with the exception of the transient speed change coincident with the angular displacement and change in phase position of the synchronous motor accompanying its change in load. The changes in load being transmitted by the belt drive on the cone pulleys being subject to any amount within the capacity of the synchronous machine and possibly passing transmission of power from the synchronous motors was eliminated and the synchronous motor rotor was geared direct to the d-c. section driving motor and the synchronous motor stator was made to rotate at a slow speed by a small variable speed d-c. motor which was geared to the stator member of the synchronous motor. Additional bearings and slip rings were provided to permit of the rotation of the stator.

In order to adjust "draw" of the sheet, or the relative speeds of the d-c. section driving motors, it was now only necessary to adjust the speed of the small d-c. motor driving the stator of the synchronous motor, by means of a hand rheostat in its field circuit; and then to

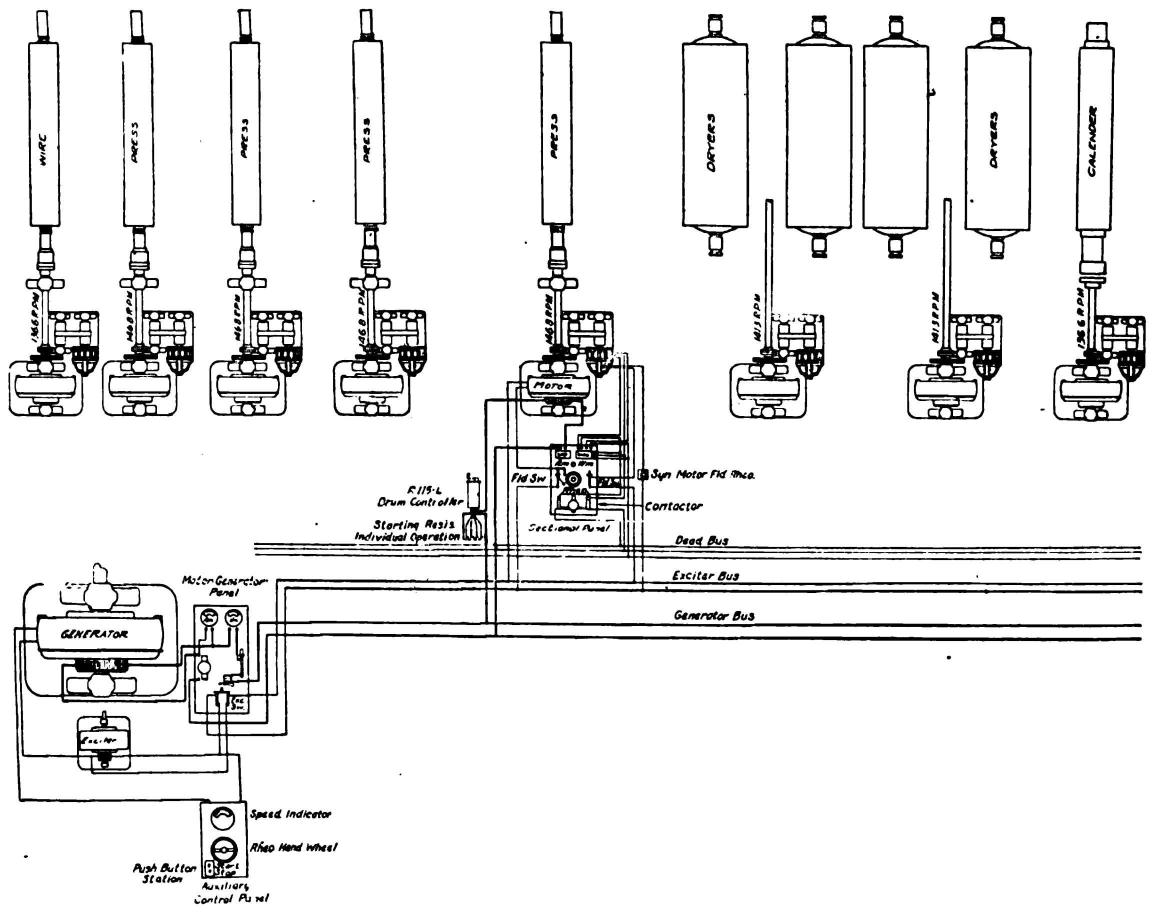

FIG. 5—SCHEMATIC DIAGRAM OF SYNCHRONOUS MOTOR TIE-IN SYSTEM OF SECTIONAL DRIVE WITH BELTS AND CONE PULLEYS

through zero torque on the synchronous machine in going from motor to generator or generator to motor (Fig. 6).

In order to maintain the synchronous motor at approximately no load, so as to be in a position to compensate for any change in either direction, it was, of course, necessary to readjust the shunt-field strength of the d-c. section driving motors at intervals, by suitable hand rheostats; a double indicating instrument being provided for each synchronous motor to indicate the approximate load as motor or generator.

This system of speed control was soon superseded by a modification wherein the belt and cone pulleys for the balance the load by adjusting the rheostat in the field of the d-c. section driving motors.

This arrangement eliminated the belt slippage factor incident to the cone-pulley belt drive, and except for variations in speed of the small d-c. motors, which were under no automatic control, the major possibilities of speed variation of the d-c. section driving motors had been eliminated. In this connection it will be seen that, while the small d-c. motors driving the stators of the synchronous motors were subject to load changes from zero to maximum and possibly even from motor to generator, if the worm gear efficiencies were high enough, considering the ratios used, the effect of the

resulting speed variations of these small motors on the speed of the d-c. section driving motors was only approximately inversely proportional to the ratio of the worm gear used in driving the stators of the synchronous motors.

"Interlock" System

The other or "interlock" system of electrical sectional paper-machine drive referred to, employed a

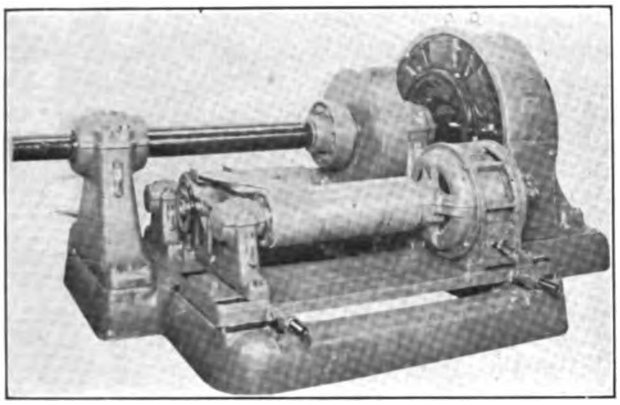

Fig. 6—Sectional Drive of Synchronous Motor Tie-In System

mechanical differential gear system for the operation of face-plate rheostats in the shunt-field circuits of the several d-c. section driving motors (Fig. 7).

A master shaft ran the entire length of the paper machine and adjacent to each of the paper machine sections, a shaft at right angles was taken off from the master shaft by means of a bevel gear. One end of the right angle shaft engaged with one member of a differential gear and the other end member of the differential gear engaged with a shaft driven by the d-c. section driving motor, through a small speed changer,

Fig. 7—"Interlock" Speed Control System of Sectional Drive

consisting of belt and cone pulleys or expanding V pulleys. The middle element of the differential gear was geared to the face-plate rheostat in the shunt-field circuit of the d-c. section driving motor. The master shaft was driven by the dryer section of the paper machine, which, therefore, became the master speed reference, and was not under regulator control.

Speed regulation of the individual d-c. section motors by this system is a function of the speed of the differential gear members, the ratio of the middle member to the rheostat arm shaft, the total resistance in the rheostat and the number of resistance steps; as well as the inherent regulation of the motors themselves and the electrical and mechanical inertia of the system. The regulation is also adversely affected by any back-lash or lost motion in the bevel, differential and rheostat gears and by the torsional elasticity of the master shaft; in fact, by any deformation or departure from synchronism or exact phase position of one part of the speed regulating system to another.

To overcome the disadvantages of the speed regulating rheostat with a rather limited number of resistance steps and of fairly high total resistance, no individual step of which is likely to give exactly the right speed, an arrangement was employed wherein the rheostat contact shoe overlaps one resistance step or button so that a very small movement of the rheostat arm will serve to transfer contact to any one of three resistance steps of the rheostat. To maintain a correct mean resistance value, it is necessary that the rheostat arm oscillate back and forth from one contact point to another, remaining in contact with either at each oscillation such a percentage of time that the mean resistance is of the required value to maintain the d-c. section driving motor at the correct average speed. Ostensibly, the only force available to cause oscillation of the rheostat arm is the d-c. section driving motor which must oscillate at the same frequency as the rheostat arm. The frequency of the oscillation is, of course, determined by the reactance of the electrical system involved, the motor field flux changes, the corresponding changes in motor torque, the inertia of the mechanical parts involved and the lost motion and torsional deformation of the gear train and shafts in the control system.

In each of the systems of electrical sectional paper-machine drive and control described, the usual method of obtaining desired changes in paper speed is by adjustment of the voltage of the d-c. generator supplying current to the armatures of each of the d-c. section driving motors.

Electrical Differential Regulator

The second step in the development of the electrical differential type of field control speed regulator system was the elimination of the a-c. system entirely and the substitution of master and section rotary contactors. These consisted of commutators or ring segments, the master and section rotary contactor being in series and serving to periodically short-circuit resistors in the shunt-field circuit of the section motor under control as illustrated schematically in Fig. 8. Both master and section rotary contactor drums or commutators operate normally at the same speed and the angular displacement of the one to the other determines the percentage of time the resistance is cut in or out of the field circuit.

The operation as will be seen, is somewhat similar to that of a Tirrill regulator, but does not have vibrating contacts.

Differing from the Tirrill regulator, there are a multiple of resistors in series which instead of being short-circuited at the same time, are short-circuited alternately in such a way as to tend to produce the least change in voltage periodically across the motor field. To handle four resistors in series, six rings on the section rotary contactor and four rings on the master rotary contactor are required.

With this arrangement, when the section rotary contactor is exactly in phase with the master rotary contactor and running at the same speed, the regulating resistance in the shunt field circuit of the d-c. section motor is short-circuited and, therefore, cut out 100 per cent of the time. When the section rotary contactor is 180 deg. out of phase, lagging behind the master, then the regulating resistance is all cut in all of the time.

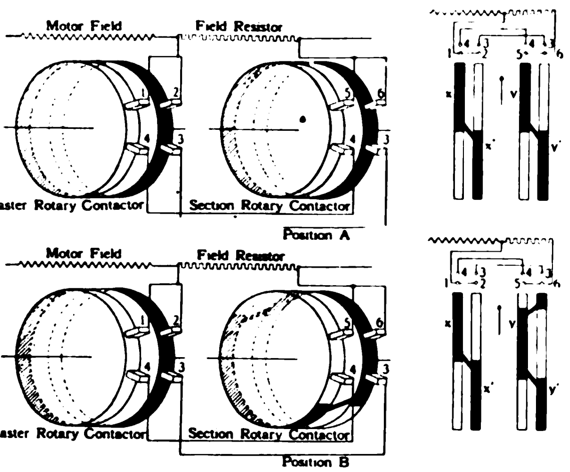

FIG. 8—SCHEMATIC DIAGRAM AND DEVELOPMENT OF MASTER AND SECTION ROTARY CONTACTORS OF ELECTRICAL DIFFERENTIAL SYSTEM

If the section rotary contactor is lagging 90 deg. behind the master, then the resistance of each resistor step is being cut in and cut out just 50 per cent of the time of each revolution of the rotary contactor drum. For any phase position of the section rotary contactor with respect to the master rotary contactor, the mean effective regulating resistance in the shunt-field circuit of the d-c. section driving motor is a direct function of the angular displacement of the section rotary contactor with respect to the master. With more than four resistance steps and a corresponding increase in the number of commutator rings, the wiring becomes very complex and difficult to trace and offers various objections for this reason.

LATEST TYPE ROTARY CONTACTOR ELECTRICAL DIFFERENTIAL SPEED REGULATOR

The third and latest development in improving and simplifying the electrical type of differential speed regulator by field control is a change in the rotary contactor design whereby it becomes in effect a continuous rheostat automatically controlled. The rotary contactor drum consists of an annular ring segment tapered at one end, forming a conducting segment and a complementary insulating segment, the two constituting the entire surface of the drum or cylinder, (see Fig. 9).

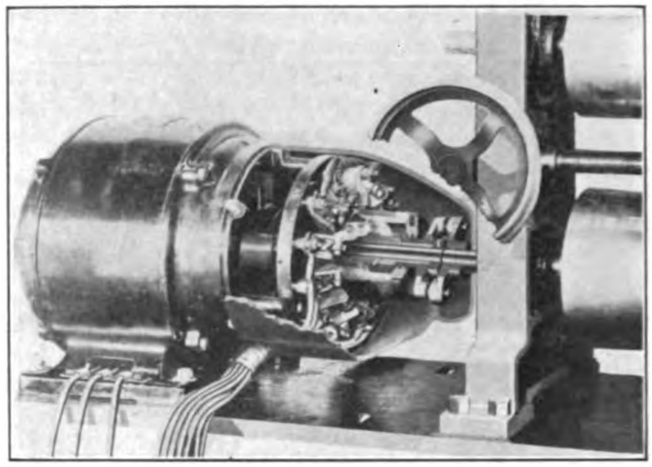

FIG. 9—LATEST SECTION ROTARY CONTACTOR UNIT OF ELECTRICAL TYPE DIFFERENTIAL SPEED REGULATOR SYSTEMS

Twelve brushes disposed radially around the periphery of the drum form a single spiral helix. Resistance units are connected between the brushes from one end of the spiral to the other in series with the shunt-field circuit of the motor. The conducting segment of the drum serves to short-circuit as many steps of resistance as there are brushes in engagement with the conducting segment at any time.

The drum is assembled on a sleeve which is mounted on the shaft of the section master synchronous motor, and is movable longitudinally on the sleeve but prevented from rotating thereon by a spline key, and the sleeve on which the drum is assembled is pinned to the shaft. The brushes are stationary and the full length of the taper of the conducting segment of the drum is equal to the "pitch" from one brush to the next in a direction parallel to the axis of the drum, plus a small overlapping allowance.

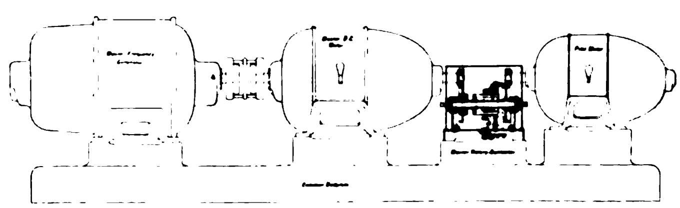

FIG. 10—MASTER SET OF LATEST ELECTRICAL TYPE DIFFERENTIAL SPEED REGULATOR SYSTEM

The speed reference in this arrangement is a master set (Fig. 10) consisting of a master frequency generator driven by a d-c. master motor and controlled with

great precision in speed by a d-c. pilot motor and master rotary contactor. It is from this master frequency generator that each of the section master synchronous motors of the section rotary contactor units operate. Both the d-c. master motor and the pilot motor of the master set operate in parallel with the d-c. section driving motors and the master rotary contactor resistors are in the shunt field circuit of the d-c. master motor. The pilot motor is the final speed reference and as it operates with substantially no-load changes and is usually located where there is little temperature change, its speed is very constant for any desired paper speed; voltage regulators being used to maintain the exciter voltage uniform and the main d-c. generator voltage constant at any desired voltage within the speed range of the paper machine.

A control speed changer, consisting of a pair of cone pulleys and belt, is provided for each section of the machine, one cone pulley being driven from the d-c. section motor to be controlled, by a chain drive; and the other cone pulley shaft coupled to the screw member of the section rotary contactor; a nut member being fixed in the outer end of the rotary contactor drum with which the screw engages. This screw member is assembled on the same sleeve with the drum to assure perfect alinement and is rotatable thereon but is restrained from moving endwise by a shoulder in the sleeve at one end of the screw and a collar at the other end on the end of the master synchronous-motor shaft. From this definite longitudinal location of the screw on the sleeve of the section rotary contactor; the spline key in the sleeve and drum, preventing rotational movement of the drum on the sleeve; and considering the engagement of the screw within the nut member of the drum; it is apparent that any difference in speed between the screw and the nut will cause a longitudinal movement of the drum beneath the brushes.

In normal operation, the screw member driven by the d-c. section driving motor through the control speed changer operates at the same speed as the nut member, drum and master; and certain resistance steps are continuously short-circuited corresponding to the brushes engaging with the continuous portion of the conducting segment of the drum. One step is being cut out periodically once every revolution, the percentage of time it is cut out corresponding with the percentage of time the brush of this step is in engagement with the tapered portion of the conducting segment which depends upon the longitudinal position of the drum beneath the brushes. The remaining resistance steps are cut in continuously, as the brushes are only in engagement with the non-conducting segment of the drum. As a result, the motor operates at a speed resulting from the mean effective resistance valve of the rotary contactor resistor—an automatic rheostat—with an infinite number of steps of infinitely small increments of effective resistance.

The extreme sensitivity of this regulating system will be appreciated by the fact that any change in angular position or phase relation of the lower cone pulley shaft of the control speed changer with respect to the master section synchronous motor, through the screw action, causes a longitudinal movement of the drum beneath the brushes and a longitudinal movement of only a few thousandths of an inch is sufficient to correct for most of the tendencies on the part of the d-c. section driving motor to change in speed. A travel of the drum of approximately three-fourths of an inch suffices to cover the range from resistance all-out to resistance all-in; and sufficient resistance is frequently used to produce a speed increase of as much as 50 per cent or more when all cut in to the shunt field circuit of the motor.

Another very important characteristic of such a differential type of regulator is the fact that any variation in speed, no matter how small, produces a positive corrective effect; and the corrective effect is cumulative and continually increases in value until the correct speed has been restored. A change in angular or phase

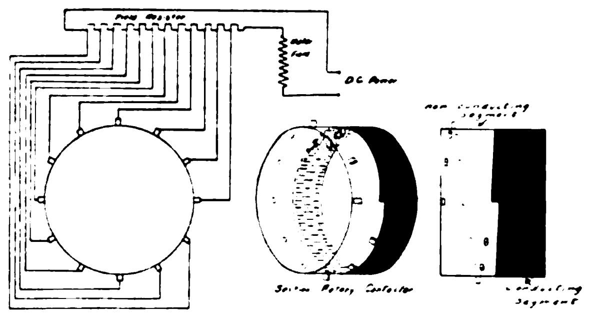

Fig. 11—Schematic Diagram and Development of Sectional Rotary Contactor Drum, Brushes and Wiring Connections of Latest Type Electrical Differential Speed Regulator Systems

position only, of the section with respect to the master serves to cut-in or cut-out sufficient resistance in the shunt field circuit of the d-c. section driving motor to maintain its speed at the same rate as before although the load may have changed.

In this respect it is interesting to observe that the d-c. motor is made to function much like a synchronous motor in so far as maintenance of speed is concerned. With the synchronous motor when a load is thrown on, the rotor falls back in phase position with respect to the generator or the frequency source and the new load is carried without more than a transient change in speed and at the same rev. per min. as before; sufficient torque having been developed in the phase displacement to carry its load. In the case of the d-c. motor with electrical speed differential field control, when a load is thrown on, the rotor falls back in phase position with respect to the master and the new load is carried without more than a transient change in speed, at the same rev. per min. as before; sufficient torque having been developed in the phase displacement and corresponding longitudinal movement of the rotary contactor drum

beneath the brushes, thereby changing the motor field resistance, so as to carry the new load without change in rev. per min. When the load is thrown off, the rotor will move forward again in a manner similar to that of the synchronous motor. The number of mechanical degrees through which the d-c. motor must fall back in phase displacement in order to carry a load of given value, at the same speed as before, depends upon the droop of the load speed characteristic curve of the motor, the resistance in the rotary contactor regulating circuit, and the ratio of longitudinal drum movement to the differential angular displacement of the rotor of the motor.

This electrical speed differential field regulator in its simplest form is not fundamentally an especially high speed regulator, nor is it especially adapted to correct with exceptional quickness for extremely heavy load changes and corresponding tendencies to speed change, although with suitable auxiliary reaction features, not necessary in paper machine drive, such conditions can be taken care of. The upper limit of speed of regulation of this system without auxiliary reaction features, is determined by the reactance of the electrical system and the inertia of the mechanical system; in other words, the speed with which the motor torque can be changed to meet the requirements of constant relative speeds, the maintenance of stability of speed and the capacity to pull into synchronism with the master promptly on starting up.

In sectional paper-machine drive all of the requirements are well within the capacity of this type of electrical speed differential regulator system and the relative speeds of the section driving motors are held constant with such precision that no variation in the "draws" of the sheet can be observed even though the paper may be traveling through the machine at the rate of 1000 ft. per min. or more which speeds are now common in modern high speed paper-making machines.

The purpose of the control speed changer between the d-c. section driving motor and the screw member of the section rotary contactor is to make possible adjustments of the speed of the d-c. section driving motors and at the same time maintaining the speed of the screw member of the rotary contactor at the same speed as the section master synchronous motor. Coincident with any shifting of the belt on the control speed changer an angular displacement of the screw with respect to the nut takes place, moving the drum longitudinally, changing the regulating resistance so as to give the d-c. section motor its new speed corresponding with the new belt position on the cone pulleys.

The coning of the pulleys of the speed changer is so small that even though a change in section "draw," or relative speeds of 25 per cent to 30 per cent can be obtained, good belt contact is always secured; and as no load is transmitted by the belt no slippage or creep that can in any way be detected takes place.

Of much value in sectional paper-machine drive and fundamental in this electrical speed differential field regulator system, is the fact that the section motors do not have to oscillate in speed to maintain the proper mean regulating resistance values; nor does any other part of this control system oscillate. The motors operate at a constant uniform speed and the exact mean effective regulating resistance values required for uniform motor speeds at any desired value are obtained by the constantly rotating tapered conducting segment of the drum of the section rotary contactor.

With the twelve steps of regulating resistance normally employed in the design of the rotary contactor, resistance values sufficiently high to meet every requirement of electrical sectional paper-machine drive can be used with practically no visible sparking at the brushes and with negligible wear of brushes or drum. The mechanical movement between the screw and nut of the rotary contactor is so small that there is practically no wear of those parts.

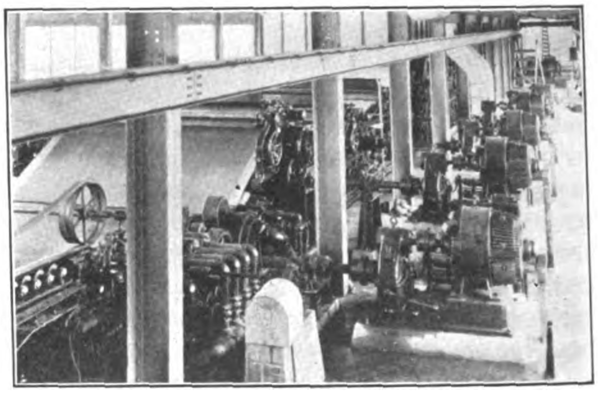

Fig. 12—Sectional Paper Machine Drive Installation of Electrical Differential Type, Field Control, Speed Regulator Systems

In order that the screw member may readily reengage with the nut member of the section rotary contactor, should it run out of engagement in shutting down or starting up, small helical springs are so disposed within the drum that they come into engagement and begin to compress just before the screw leaves the nut so that there is a sufficient force to cause the reengagement of the screw and nut as soon as the speeds of the respective members are such as to permit.

Full automatic push-button control of starting and stopping operation, "inching" and changing of "draw," as well as the adjustments of the speed of the machine as a whole for any paper speed within its range, adds greatly to the flexibility and makes the equipment practically fool-proof.

Rumors have been heard of the development in Europe of an a-c. type of electrical sectional paper machine drive wherein commutator-type variable speed a-c. motors are understood to be used for driving the paper-machine sections; with a differential mechanism for automatically shifting the motor brushes to control

the relative speeds of the section driving motors; and by changing the master speed to effect speed adjustment over the entire range of the paper machine. Information is not at hand to confirm the successful installation and performance of this type of drive and control.

The use of electrical sectional paper machine drive has made possible the operation of paper-making machines economically at higher speeds than was possible with existing mechanical systems of drive. This was largely due to the rather limited amount of power that can be transmitted by means of cone pulleys and belt drive. With electrical sectional paper-machine drive a very considerable saving in power is accomplished and maintenance is reduced to a minimum as compared to mechanical drive. On account of the elimination of belt slippage and sectional speed variations incident thereto, breaks in the paper are greatly reduced and the operating efficiency materially increased. More exact speed regulation throughout is made possible and many other distinct advantages in specific cases and kinds of paper machines and types of product have added greatly to the general efficiency, flexibility and operating technique in the modern paper-making machines.

The object of this paper has been to chronicle the advance in the art of electrical sectional paper-machine drive and control, to indicate the several more or less distinct lines of development; to outline the outstanding characteristics of each of the several types and to point out novel and rather unique methods, so far as the author knew, for obtaining speed regulation of great precision and for the making of d-c. motors to operate at synchronous relative speeds.

The author wishes to express his appreciation of the privilege of using in this paper illustrations kindly furnished by the following: Vocational & Educational Committee of the Paper Industry and McGraw-Hill Book Company, Publishers of "Manufacture of Pulp and Paper." Discussion at New York Section Meeting

HYDROGEN AS A COOLING MEDIUM FOR ELECTRICAL MACHINERY[1]

(KNOWLTON, RICE & FREIBURGHOUSE)

NEW YORK, N. Y., OCTOBER 23, 1925.

G. E. Luke: In determining the probable temperature rise of any electric machine, we may first start with the calculation of the volume of fluid necessary to be circulated through the machine in a given time.

Thus, comparing air and hydrogen as possible fluids, the volume of hydrogen required will be only 2 or 3 per cent more for hydrogen than for air, on the basis of the same temperature rise of the gas due to the same loss absorbed. This temperature rise in the gas used should not be over one-half of the maximum temperature rise of the ventilating surfaces.

The ventilating-surface temperature can be calculated, when the surface-heat-transfer coefficient (K) is known. Considerable data regarding this constant (K) are available for air[2]. However, little experimental data are published for hydrogen. Some experimental tests by Rice[3] on a small cylinder (axial flow) gave a heat transfer for hydrogen 137 per cent of that for air at an average velocity of 5000 ft. per min. On the other hand Rice[4] gives for large plane surfaces this heat transfer (K) as proportional to $\frac{\rho\, k}{\mu}$, where ρ, k, and μ are the density, thermal conductivity, and viscosity of the gas, respectively. On this basis, the unit heat transfer from the surface will be about the same for hydrogen as for air.

Pohl[5] has calculated from Nusselt's[6] work this coefficient (K) to be about 50 per cent greater for hydrogen than for air. The equation given by Nusselt can be reduced to the form[7] of

$$K \,\alpha\, k^{n-1} \quad (\rho\, C_p\, V)^n$$

where

K = unit surface heat transfer
k = thermal conductivity of the gas
ρ = density of gas
C_p = specific heat of gas
V = velocity of gas.

This equation is also practically the same as that given by Pohl. Thus, the ratio of the heat transfer with hydrogen to that obtained with air will depend upon the exponent (n) of the velocity factor. Thus, with (n) = 1, the ratio is about 98 per cent and with n = 0.786 as given by Nusselt the ratio becomes about 150 per cent. The writer has found that for turbulent gas flow where the gas path is straight and uniform, the heat loss varies as $V^{0.85}$ to $V^{0.95}$; and where the air path is irregular the unit heat loss varies as $V^{0.75}$ to $V^{0.85}$. Hence, it is estimated that in an average generator the unit heat dissipated with hydrogen will be about 25 per cent greater than with air, which is not far from the figure given in the paper.

The paper states that the rate of heat transfer in the coolers should be about three times greater for hydrogen than for air. This figure seems too high; it might be correct for the tubular surface but is probably too high for the fin surface, and this later surface is usually several times greater than the tubular surface. The writer estimates the heat transfer in the usual type of cooler to be 50 to 100 per cent greater for hydrogen than for air. This, of course, is a big factor since the cost and size of the present cooler can be reduced.

The majority of the iron and copper losses in the core have to flow an appreciable distance through the iron to the ventilating surface. This necessarily requires a temperature drop. Where radial ventilation is used, the heat flow is mainly across the lami-

7. This was done on the basis of (K) being independent of the temperature of the gas and surface, which is practically true of the range in which we are interested.

nations, in which direction the heat flow has a high-resistance path due to the varnish and gas film between the laminations.

With one-watt flow across a 1-sq. in. section of the usual 0.017-in. varnished iron laminations, the temperature drops are approximately:

Deg. cent. drop through

Iron	Varnish	Gas	Total
1.0	11.0	(Air) 21.0	33 deg. cent.
1.0	11.0	(Hydrogen) 3.0	15 deg. cent.

Hence the rate of heat flow across the laminations should be at least doubled by using hydrogen as the cooling medium.

One of the most important portions of the heat-flow path is from the copper through the insulation. This part has more influence in limiting the rating than any other since the thermal conductivity of insulating materials is so low. The thermal resistance through ordinary insulation in air is about 3000 times greater than that through copper. All insulation in the built-up wrapper will necessarily contain some small gas spaces; hence these gas spaces, if they are air, will offer considerable resistance to the heat flow, since the thermal resistance of air is about ten times that of the insulation itself.

To check the above, the Westinghouse Research Laboratory has made tests on the thermal conductivity of the insulation on turbo armature coils. The results show that the thermal conductivity of these mica insulations as used is from 150 per cent to 250 per cent as great with the coils in hydrogen as obtained on the same coils in air. The particular ratio depends upon the compactness of the insulation; that is, the percentage gas space in the wrapper. This increase in heat flow with the hydrogen cooling system will result in a considerable reduction of the conventional "hot spot."

The temperature of the rotor copper is usually the limiting temperature, with air as the cooling fluid. It will also tend to be the limiting factor when hydrogen is used, due to space limitations and to appreciable temperature drops through the solid iron core which will be unaffected by the gas used for cooling.

In the tests given by the writers, the apparatus simulated conditions found in a solid rotor, where there would be a considerable temperature drop through the iron. However, in a ventilated rotor, even better results could be expected, since this drop through the iron would be reduced.

Comparative Corona Effects Under 15,000 Volts for 19 Days.

As to the insulation, the writer also agrees with the authors, that its life would be materially increased in a hydrogen atmosphere. Oxygen in the air is the main factor which causes mechanical deterioration. Dr. C. F. Hill made tests regarding the corona action upon insulation in air and in hydrogen. The results were even better than those quoted in the paper in favor of hydrogen. Two kinds of insulation were tested; one varnished cambric, the other a mica wrapper. Both were wound on a glass tube and 15,000 volts a-c., 60 cycles, was applied for 19 days. Most of the stress was through the glass tube but a heavy corona could be seen covering the insulation. At the end of the test, the sample in hydrogen was unchanged, while the one in air was radically altered. The varnished cambric was bleached and was very brittle, the paper in the mica wrapper was completely destroyed. The hydrogen prevented the chemical action found on the sample in air.

As to the possibility of explosive mixtures with hydrogen, the average of nine investigations[8] gives the explosion limits as 7.9 to 69.4 per cent hydrogen in a hydrogen and air mixture.

An indicating or recording instrument for giving the purity of the mixture can be easily obtained by using the conductivity-cell bridge method[9]. This is exceedingly accurate and is well suited for such purposes.

Gases other than hydrogen can be used for a cooling medium. Thus helium, (if made available in the future) is an inert gas with a density about 1/7 of that of air. Its specific thermal capacity is about 73 per cent of that of air and its thermal conductivity is almost as high as that of hydrogen. Such a gas would be preferable to the operating men.

L. B. Bonnett: From the user's point of view, there are some very striking things in this Table II, showing the results of the tests on the small 3000-kv-a. machine. If we can expect to get a one-third increase in capacity out of the same material, presumably at approximately the same price, we are getting something that is very interesting indeed. At that increased rating the total loss is practically the same, in fact, it has slightly decreased.

Looking at it from a little different point of view, many of us use stand-by machines that are in operation ready to take load and the no-load losses are a very important factor. If the use of hydrogen can reduce those losses by say 50 per cent, that indeed is a very great advantage for this particular duty.

This light-load loss too, has another rather interesting application. Turbo-generators are commonly equipped with closed ventilation and air coolers and very frequently condensate is used for cooling. Since the light-load losses are usually more than half the full-load losses, the condensate at light loads has to be recirculated in a more or less complicated fashion or some other means of cooling supplied. This very great reduction in the fixed losses would mean that the losses would decrease more nearly in proportion to the load and the condensate itself might be perfectly adequate for cooling the machine all the way down.

With all the advantages mentioned in this paper,—a real astonishing catalog of advantages,—it behooves us, the users, not to be too sure that the one disadvantage, the possibility of an explosion, is an insurmountable defect. I believe our serious consideration is well worth while.

W. B. Kirke: It is hoped that further investigation on the life of insulating material when operated in hydrogen as compared to operation in air can be made. It might be found quite practical to operate at higher temperature limits in hydrogen than have been standardized for operation in air. It is also to be hoped that this paper will be supplemented by others which will indicate the installation cost of such a ventilating system, and some idea of the equipment necessary for its operation.

C. J. Fechheimer: A few years ago the only media for cooling considered were air, oil and water. The use of oil or water has never met with favor in this country, even though certain important advantages could be secured by their adoption. It seems that electrical engineers were not aware until a few years ago that the gains to be obtained by means of some other gas were sufficient to warrant employing it instead of air. Even after the suggestion of the use of a lighter gas was offered to the designing engineers, they did not immediately consider its adoption. The gas proposed in the Schüler patent is hydrogen, and the first thought that entered the mind of the engineer was the danger of explosion. It was not until he learned that

8. See article by C. J. Rodman, *Elec. World*, 6-24-22.

9. Thermal Conductivity for Analysis of Gases. Technical Paper, Bureau of Standards, No. 249

detonation will not occur if hydrogen constitutes more than about 70 per cent of a mixture with air, that he felt that possible gains were great enough to warrant investigation. We now have records in this paper of the studies and researches given by three engineers of one of the leading electrical manufacturing companies on this subject. It is the first public presentation to a group of engineers of a systematic study of this advance which it is believed will considerably modify the design and construction of large electrical machines in the future.

Of the various gains to be obtained by means of hydrogen, there are two of prime importance. The first is the enormous reduction in windage loss due to the low density; and the other is the decrease in thermal drop through the insulation. In the large high-speed steam turbo alternator the windage is the greatest loss and may be as high as 50 per cent of the total. By substituting hydrogen for air this loss becomes almost negligible. In addition to the gain in efficiency, the temperature rise due to the windage becomes insignificant, whereas in the present day machine it is from 5 to 10 deg. cent.

It has been recognized for a number of years that the tiny voids in insulation reduce the net thermal conductivity of the wrapper to about 50 to 75 per cent of that which would obtain if the wrapper were solid throughout. Now we find that, because hydrogen diffuses so readily, hydrogen will supplant the air and the resistance to heat flow in the voids will be decreased to about one-seventh, and the net conductivity will be greatly improved. The authors find 30 to 58 per cent improvement in net conductivity for the field core, and they estimate about 42 per cent gain for the armature coil. Also, because the thermal conductivity is high, the transverse drop through a package of laminations is reduced and the drop from the surface is decreased. So the authors find that as a result of all the gains, a certain turbo-alternator can be rated about 30 per cent higher by substituting hydrogen for air. But that is not the final word; to take full advantage of the properties of hydrogen, the machine should be proportioned differently. For example, the velocities of the gas in the vent ducts can be increased, and the lamination-package thickness can be enlarged. Owing to the reduction in total losses, the volume per unit time of the gas may be lowered.

Also, as the authors state, there is a likelihood of reducing thickness of insulation wall in the stators, when mechanical considerations do not enter. At present it is difficult to state how much the weight, cost and size of the generator may be decreased, if full advantage of all gains is taken in the design. But certainly the cost will be reduced considerably.

There are a few points which are not covered in the paper. Two will be mentioned. In very large machines as designed at present, it is not feasible to evacuate in order to replace the air by hydrogen or vice versa, as the stresses arising from atmospheric pressure are prohibitive. While it is possible so to proportion those parts as to prevent collapse while evacuating, it is believed that an alternative plan which will maintain all parts at or near atmospheric pressure should be entirely satisfactory. The plan is to replace the air by an inert gas, such as nitrogen, and then to replace this inert gas by hydrogen. Tests are now being conducted for determining how satisfactorily this can be done.

Another feature is that to minimize leakage, suitable stuffing boxes should be provided where the shaft passes through the openings in the end bells. It seems at present that this is the most difficult part of the problem. Experimental work is now under way on a water-gland seal; and with this device it is believed that the leakage will be negligible. Ample precautions are being taken to avoid the escapement of water into the generator.

The authors have used the thermal-conductivity method for determining the extent to which the hydrogen is contaminated. Another method consists of a small fan driven at constant speed, the inlet and outlet of which join into the system. The pressure which the fan generates is directly proportional to the density of the gas, and the pressure difference between the inlet and outlet can readily be indicated on an ordinary manometer. The relation between the percentage of hydrogen and the reading on the manometer is linear, assuming that air is the contaminating gas. The authors state that with the thermal conductivity method, 1 per cent impurity will change the potential drop from 11.5 to 12.5 volts or 8.7 per cent. With the density method, the same change in constituency will alter the manometer reading 13.3 per cent. Thus, there is greater sensitivity, and it is believed that the device is more direct and simpler than the thermal method. The density method can be used to operate a signal, or possibly to operate switches automatically.

While further experimental work must be done prior to the building of machines for service, the outlook is very bright, and it is believed that the time is not far distant when machines using hydrogen will be in operation.

J. Rosen (communicated after adjournment): The authors' investigations into the difficulties of ventilation of electrical machinery will be welcome as being of theoretical interest, more particularly as they have some bearing upon the conditions for generating at higher voltages than have been customary in the past. I do not think, however, that the use of hydrogen can be considered practicable at the present moment. It has the drawback of increased cost and complication in design. Further, I do not think that the danger of forming an explosive mixture can be altogether avoided. The closed-circuit system of ventilation has now been generally adopted for large alternators. The advantage with the use of hydrogen in avoiding the danger of fire also applies to the closed-circuit system using air, as, with the limited amount of air in the latter, the damage that can be done by fire is limited. I illustrate this by the following example:

The volume of air in the alternator and ducts of the closed-circuit system of a 25,000-kv-a. alternator at 3000 rev. per min. is approximately 2000 cu. ft. containing 40 lb. of oxygen. This quantity of oxygen could consume 15 lb. of carbon or 40 lb. of wood, but as the principal product of combustion is carbonic acid gas, and a flame is extinguished when only 4 per cent of carbonic-acid gas is present, the amount of wood consumed would only be about 2 lb. The total weight of combustible material in the alternator, including wood packing and insulation exceeds 1000 lb. It is obvious therefore that the fraction of material that would be damaged, or consumed by fire would be negligible.

To reduce the losses in the fans attached to the rotor body, I prefer to use separately driven fans, and to adopt a suitable system of ventilation to reduce the pressure drop through the alternator to a minimum. By this means, an improvement in efficiency of one per cent can be obtained. In the ventilation scheme described in the paper[10] "Some Problems in High-Speed Alternators and their Solution," the air-pressure drop through the alternator is reduced to approximately 3-in. water gage.

Robert Pohl: The valuable research which Messrs. Knowlton, Rice and Freiburghouse publish on this subject might, with advantage be extended to the use of methane. In a paper published in 1923 (*Archiv. F. Elect.*, June 30, 1923, p. 361) I defined what one might term the cooling constant of various gases and showed that this constant is even higher for methane than for hydrogen. Since methane is also cheaply obtained as a by-product, its use may well be considered. Although the risk of explosion is not serious in any case the much smaller area of "exploibility" would be a practical advantage.

E. H. Freiburghouse: From the discussions it is evident that other engineers have also been giving active consideration to the subject and almost all of them seem very optimistic for the future use of hydrogen as a cooling medium for electrical machinery.

Opinions and data which have geen given seem, in the main, to agree quite well with those given in the paper. Although the

10. *Journal I. E. E.*, Vol. 61, No. 317, p. 447-8.

points raised by Mr. Fechheimer were not covered in the paper they have been carried out or considered during the investigation by the authors.

Mr. Fechheimer mentions the use of an inert gas, such as nitrogen, for replacing the air and hydrogen in the generator before and after the installation of the hydrogen. Nitrogen was used for this purpose during the heat tests which were made upon the 3380-kv-a. generator.

It was realized from the beginning that to prevent the leakage of hydrogen between the rotating and stationary parts of the generator was the most difficult and expensive problem to solve. Two different types of seals have been developed each of which reduces the leakage to a negligible value. In the liquid seal it is thought that oil is preferable to water.

A small fan driven at constant speed was used in some of our earlier investigations to determine the density of the gas mixture and, as Mr. Fechheimer states, it has several attractive features.

If hydrogen is used as a cooling medium, the authors believe that Mr. Rosen will agree that fans upon the rotor of the generator are preferable to separately driven fans. We believe that the pressure drop of the air through the generator should greatly exceed the 3 in. of water which Mr. Rosen mentions, if the necessary velocity of the air is obtained for a high value of unit-surface heat transfer.

THREE-PHASE, 60,000-KV-A. TURBO ALTERNATORS FOR GENNEVILLIERS

(Edouard Roth)

New York, N. Y., October 23, 1925.

W. F. Dawson: The author is to be particularly congratulated on the production of a very fine machine. It has shown low heating, many novel and ingenious ideas, good mechanical engineering, and, I should say, very good efficiency. But there is one feature of the design that is quite startling to us in the United States. I know I speak for myself and for my immediate colleagues although I do not know that I speak for other manufacturers in this country.

Mr. Roth has laid particular stress on the fact that, by means of his leakage slot, he has achieved very low short-circuit current, current as a result of sudden short circuit. He has also pointed out that he has done this in preference to using very high armature reaction and a correspondingly low flux. Nevertheless, his armature reactions are proportionately higher than we would feel safe in using.

If we go back to the *Electrical Review* of London, April, 1923, we find there the saturation and impedance curves (page 646, issue of April 27th, 1923). The "saturation," 6000 volts is, expressed in field amperes, about 136 amperes. The short-circuit impedance at 4200 amperes is approximately 270 amperes. We feel that in designing alternators, particularly those to carry inductive load, the excitation required for normal ampere short-circuit impedance should not be much in excess of the excitation required at normal open-circuit voltage.

I understand that it is the practise of many European designers to allow a high short-circuit impedance, making a machine in which the full-load field excitation is three times the open-circuit excitation.

I also understand that somehow in general they are successful with it, probably because the increment of the load is small compared with the total load and perhaps, too, because of the more general use of automatic voltage regulators. I have had at least two or three glaring cases in my own practise, in which, before I realized the importance of designing for "voltage stability," the voltage would break down at or about full load. One case was in a cotton mill where one turbo alternator was carrying the entire load of the mill and, according to the calculations which I learned later how to make, the machine should have had a voltage breakdown at about 2300 kw.; it was rated at 2500 kw. I furnished a new armature which had lower armature reaction and, of course, higher flux, and the trouble disappeared.

I have had other cases into which it is not necessary to go; we have also noticed it particularly in the case of ship propulsion machines where one turbo alternator is to take care of the induction-motor load. That machine, or a group of machines, will be running along satisfactorily, but rough sea will increase the load on the motors and the voltage falls faster than the amperes increase, hence the kv-a. is reduced and the motors break down.

I should like the author to tell whether he has had any such experience?

Philip Torchio: Mr. Roth's paper gives an excellent illustration of the progress in large turbo alternator design. Some of the special features of his machines will undoubtedly be commented upon by expert designing engineers. From an operator's standpoint, I wish to express my sincere appreciation of the remarkably low temperature rises of the copper in the stator and the rotor. The long narrow slots with an abundance of radiating area, the winding bars of the armature, with their careful assembling to eliminate eddy-current losses and a combination of axial and radial ventilation, have been used to secure results which are superior to any with which I am acquainted. In making this statement I wish to add that I have not had the time to analyze closely how much the results are influenced by the differences in number of poles and the relative capacities of the machines compared. Mr. Roth has already mentioned how the difference in number of poles for machines of same capacities affects the total weights of such machines. Undoubtedly to some extent the number of poles imposes limitations upon the temperature rises. The employment of leakage slots may, however, be of a decided advantage in giving remarkably low temperature rises.

As to the advantage of reducing the short-circuit current, I shall be very much interested to learn of the comments of designing engineers. In our practise we have, for more than 13 years, considered it essential to the safe operation of a large system to install reactors between generators and buses so as to protect the main bus against sort-circuit failures in generator windings. In such installations, therefore, the reduction of short-circuit current on sound generators is limited by the external reactors, and designers may not find it necessary or desirable to employ leakage slots. This is a problem that should receive consideration in the discussion.

C. M. Laffoon: These generators are unique, in that certain design features are carried to rather extreme limits. The author states that the 45,000-kv-a. turbo generators, which were installed in the Gennevilliers station in 1922, were the largest four-pole turbo generators built, up to that time. This statement is somewhat liable to misinterpretation because these are 50-cycle machines and the design and construction of a given size, four-pole generator, operating at 1500 rev. per min. are not so difficult as the design and construction of a four-pole, 60-cycle generator which operates at 1800 rev. per min. At the time these Gennevilliers generators were installed, they were rated at 40,000 kv-a. At the same time the Westinghouse Company was installing the first of the Hellgate generators, which were rated at 43,750 kv-a., but were six-pole, 1200-rev. per min. The Westinghouse Company has since built generators of this same kv-a. rating but of four poles, 1800-rev. per min. Recent tests on these generators show that they will carry 50,000 kv-a. at 80 per cent power factor and do not exceed the standard guarantee of 60 deg. cent. temperature rise on the armature winding and 90 deg. on the field winding. The Westinghouse Company has also built 62,500-kv-a. generators for the Brooklyn Edison Company, but these were of six poles and 1200-rev. per min. At the present time a four-pole, 1800-rev. per min. 62,500-kv-a. 80 per cent power factor turbo generator is being developed by the Westinghouse Company and 1800-rev. per.

min. generators with ratings as high as 75,000 kw. and 90 per cent power factor appear feasible to build and operate.

It is to be noted that this generator is being wound for 6000 volts, which is a relatively low voltage for 60,000-kv-a. rating. In the United States the majority of central stations generate at voltages varying from 11,000 to 13,800 and with some companies there is a decided tendency to specify a final insulation test voltage of three times normal plus 1000 instead of the standard insulation test of twice normal plus 1000. However, some utility companies are considering the advisability of having generators wound for lower voltages and solidly connecting the generators to step-up transformers without any intermediate circuit breakers. In this case the final insulation test voltage would be on the order of four times normal plus 1000. On the other hand, other companies in the far west are considering 16,500-volt generators. At the present time there does not appear to be sufficient data available to determine the maximum voltage stresses due to switching, short circuits, and lightning to which the generator windings may be subjected during actual service conditions. Until these data are available, it will be difficult to determine the voltage and insulation strength which will give the greatest protection against over-voltages and still not seriously affect the cost and the reliability of operation from the standpoint of temperature.

In going over this paper the following outstanding features are of paramount importance.

1. Small physical dimensions.
2. Low short-circuit ratio, i.e., a low ratio of no-load field ampere-turns to the field ampere-turns which are required to maintain full-load sustained armature current.
3. High leakage reactance.

In comparing the physical dimensions of this 50-cycle generator with those of a four-pole, 60-cycle, 1800-rev. per. min. generator of the same kv-a. rating, it is noted that the overall length of the active iron including the ventilating ducts is considerably less than that required for the 60-cycle generator. This is partly due to the fact, as previously indicated, that, for a given rotor diameter the design and construction of a 50-cycle generator are less difficult than they are for a 60-cycle generator of the same rating and number of poles. Since the mechanical stresses in the rotor body and retaining rings are proportional to the square of the peripheral speed, approximately 20 per cent more ampere-wires per inch of wound periphery can be obtained for a given rotor diameter for the 50-cycle generator than for the 60-cycle generator on the basis of the same number of poles. In either case for a given short-circuit ratio, the kv-a. output is proportional to the product of the total flux, rotor ampere-turns, and rev. per min. Hence, the length of the active iron of the 50-cycle generator would be appreciably less than that of the 60-cycle generator and would be equal to that of the 60-cycle generator multiplied by the inverse ratio of the total flux in the machine. Since the iron loss varies approximately as the second power of the flux density and about as 1.2 power of the frequency, the relative total flux for the two cases will depend on the effectiveness of ventilation for each generator. An examination of the temperature data of Table I shows rather high stator-iron temperatures as compared to the temperatures on the bare copper. This indicates that the stator iron is worked at rather high magnetic induction and consequently this feature also tends toward a short machine.

From Fig. 13, the short-circuit ratio of this 60,000-kv-a. generator is approximately 0.475. This same value was obtained from the specified dimensions and design data which were given for the armature and field windings. The short-circuit ratio of a Westinghouse generator of the same rating would be on the order of 1. Similarly, the full-load field ampere-turns are approximately 3.1 times the no-load field ampere-turns, whereas, in the case of the Westinghouse generator, the ratio is about 2 to 1. This means that the armature ampere-turns are high as compared to the no-load field ampere-turns and a small change in the armature load current produces a large change in generated voltage and kw. output. Fig. 2 herewith shows the relation between armature current and voltage, armature current and kw. output, and kw. output and voltage for the 60,000-kv-a. Gennevilliers generators and for a 62,500-kv-a., 60-cycle, 1800-rev. per min. generator with the field excitation corresponding to full rated kv-a. at 80 per cent power factor. The curves for the 60,000-kv-a. Gennevilliers generators were determined from the specified design data and physical

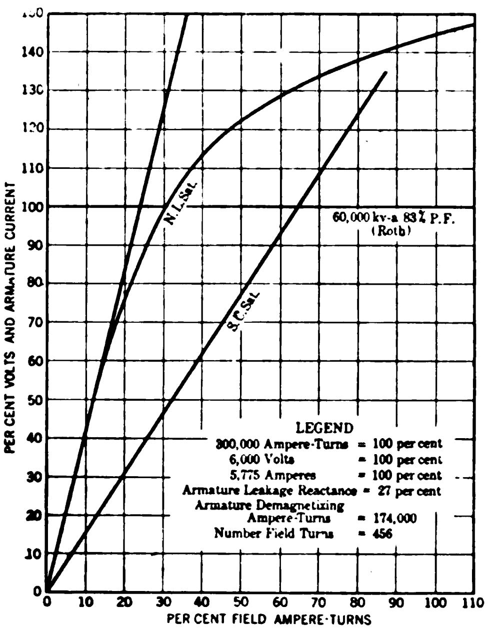

Fig. 1—No Load and Short Circuit Saturation Curves 60,000-Kv-a., 50,000 Kw., 83 Percent Power Factor 6000 Volt, 50-Cycle, 1500-Rev. Per Min., 5775-Ampere Gennevilliers Generators

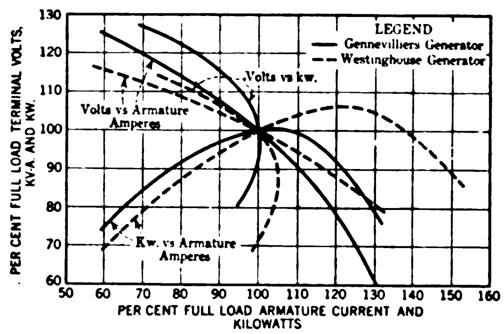

Fig. 2—Load Characteristics for 50,000-Kw. Turbo Generators 80 Percent Power Factor and Constant Field Excitation

dimensions of these machines, and the no-load and short-circuit saturation curves of Fig. 1 herewith. The curves in Fig. 1. are the same as given in Fig. 7 of the paper for the 45,000-kv-a. generators but modified to suit the design constants of the 60,000 kv-a. generators. An analysis of the load curves in Fig. 2 shows the following comparison of the stability characteristics of the two generators when operating at 7 per cent power factor loads, and with a field excitation corresponding to full-load 80 per cent power factor conditions:

1. The maximum kilowatt output of the Westinghouse generator is 106 per cent whereas that of the Gennevilliers generator is only 100 5 per cent.

2. The Westinghouse generator will deliver 100 per cent kilowatt output with an armature-current range of 100 to 138 per cent, whereas the Gennevilliers generators will deliver full kilowatt output over an armature-current range of 100 to 108 per cent only.

3. The rate of change of terminal voltage with respect to kilowatt output, at the point of 100 kw. output, is approximately five times as great for the Gennevilliers generator as for the Westinghouse generator.

This comparison shows that the Gennevilliers generators, which are designed with a low short-circuit ratio and much more sensitive to sudden changes in load than the Westinghouse generators which have a short-circuit ratio which is more than twice as large. Hence, when operating alone or in parallel with other generators which have the same characteristics, it would be necessary to provide voltage regulators in order to maintain reasonably constant voltage for rapidly changing loads on the system. The application of quick-acting voltage regulators to these machines is difficult because of the extremely wide range in field current required in going from no-load to full-load operating conditions.

If these generators were operated in parallel with other generators which have greater stability under changing load conditions, that is short-circuit ratios of 1 or more, it would be necessary not only to provide high-speed voltage regulators but the characteristics of the voltage regulators and of the governors on the driving turbines would have to be carefully designed to meet the particular conditions. But even then, there is always the possibility that hunting action may take place between the generators with poor and good regulating characteristics and reach such magnitudes as to cause the machines to pull out of step.

In the case of high-voltage transmission system the design of the generators should be such that the armature ampere-turns are small as compared to the no-load field ampere-turns; that is, the short-circuit ratios should be high.

A generator designed with a low short-circuit ratio has considerably smaller dimensions than one designed for a high short-circuit ratio on account of the fact that the portion of the field ampere-turns which is used to give stability in the high short-circuit ratio machine is used to give kv-a. output in the case of the generator with the low short-circuit ratio. There is no doubt but that generators with short-circuit ratios as low as 0.475 can be operated satisfactorily with hand regulation on systems which have reasonably smooth load curves, as well as with automatic voltage regulators on systems with varying loads, provided the voltage regulators and turbine governors are designed with the necessary characteristics. However, there is no doubt that such generators require careful attention and are likely to give trouble during transient disturbances or sudden load changes. The extent to which it is desirable to reduce the short-circuit ratio, and hence increase the output for given physical dimensions depends, to a large extent, on the load characteristics of the system on which the generator is to operate, the characteristics of the generators which operate in parallel, the characteristics of the voltage regulators and turbine governors, and the amount of attention the operators give to the machine. Our own experience and observation indicate that turbo generators which have short-circuit ratios of approximately unity give satisfactory operation on the average central-station system in this country. However, this value of short-circuit ratio can and must be widely departed from in the case of generators which operate on systems or central stations in which greater or less generator stability is necessary.

The leakage reactance of the armature winding of the Gennevilliers generators is unusually high for turbo generators. A large portion of this reactance is obtained by providing leakage slots immediately above the slots for the main winding. If it is necessary to limit the initial values of short-circuit current to values comparable with those delivered by slow-speed waterwheel-type generators and the reactance must be within the generator, this is an attractive method of obtaining a high reactance. The mechanical forces on the end turns are reduced and the increase in reactance due to the air slots does not materially increase the iron loss in going from no-load to full-load conditions. However, it must be remembered that the use of these slots increases the over-all diameter of the machine, the cost, and the value of the iron losses. The increase in diameter and cost are partially offset by the fact that more room is obtained for the armature copper. An increase in diameter not only adds to the weight but also the shipping difficulties. The iron loss in the stator teeth is usually about one-half of the value of the loss in the core. The additional tooth projections increases the iron loss in the stator teeth about 60 per cent and this corresponds to an increase in the total iron loss of approximately 20 per cent. In the case of particular generator, the additional 20 per cent increase in iron loss corresponds to 0.15 to 0.20 per cent reduction in the generator efficiency.

The leakage reactance of a 60-cycle, 1800-rev. per min. Westinghouse turbo generator of the same rating would be from 15 to 18 per cent, and the end turns of the armature winding are sufficiently well braced to withstand a three-phase short circuit at the generator terminals under no-load initial conditions and 110 per cent of normal rated voltage, as required by the 1925 A. I. E. E. Standards. So far as the initial values of the short-circuit currents are concerned, this condition corresponds very favorably with the actual conditions under full-load operation. In machines of this class the percentage of winding failures due to short circuits has been very small. In general we feel that the end turns can be sufficiently well braced to withstand short circuits that occur under usual operating conditions when the leakage reactance of the generator is 10 per cent and above. If still greater protection is desired it can be obtained by making further improvements in the bracing instead of increasing the leakage reactance by a method which involves an increase in cost and overall diameter, and a decrease in the generator efficiency of 0.15 to 0.12 per cent.

A comparison of the temperature rises obtained by detectors C, 10, and 12 show that when carrying 50,200 kv-a., the temperature rise on the bare copper at the midway axial position is only 37.5 deg. cent or 10 deg. higher than the temperature rise of detector placed between the conductor sections. Using this same temperature difference, the temperature rise of the bare copper near the ends of the machine would be 50 to 56 deg. cent. The iron temperatures vary over quite a wide range, being particularly high in the teeth at the ends of the machine and in the core at the middle of the machine. The temperature rises of the armature and field windings compare very favorably with corresponding temperatures obtained on Westinghouse generators which have a similar system of ventilation. This particular form of the multiple-path radial system of ventilation is exceptionally well worked out from the standpoint of utilizing the frame space behind the stator punchings, and gives excellent results in stator and rotor ventilation. The air requirements for the generator are approximately 105,000 cu. ft. per min. and the author states that approximately 26.5 per cent of the air passes through the rotor body. This is an unusually large percentage for the rotor and no doubt is responsible for the low temperature of the field winding.

In order to determine the losses of turbo generators when operating under normal load conditions, it is necessary to know the volume of cooling air and its temperature rise for any particular load condition. Various methods have been suggested and used for measuring the amount of air passing through the machine. When the air discharges to the atmosphere the air volume can be determined with a good degree of accuracy by

measuring the velocity head at the discharge from a specially designed stack or nozzle. The discharge velocity can be made practically uniform over the entire discharge section by properly designing the stack and passing the air through fine-mesh screens as it leaves the generator. However, the most promising method is the one suggested by the author, in which the generator is operated as a synchronous motor under no-load conditions and the electrical input and final temperature rise of the cooling air are measured for two widely different values of voltage. If temperature detectors of the thermocouple or resistance type are properly placed in the inlet and outlet air ducts and due care exercised in making the measurements, the air volume can be determinded with a satisfactory degree of accuracy. Since most large turbo generators cannot be tested at the manufacture works under normal load conditions, it seems very essential that all such generator units should be so arranged that the steam end can be disconnected and the generator operated as a synchronous motor. The operating companies should have sufficient interest in the performance of the machines to be willing to cooperate with the manufacturers in making the tests.

Briefly summarizing, the 60,000-kv-a. turbo generators as described by Mr. Roth are exceedingly interesting on account of:

(1) The small physical dimensions which result from the following:

a. The generators are designed for 50 cycles at 1500 rev. per min., and consequently the stator iron can be worked at a higher magnetic induction than in a 60-cycle generator;

b. The short-circuit ratio is unusually low; that is, the portion of the field ampere-turns which is used to give stability in the case of a Westinghouse generator is used to give kv-a. output in the Gennevilliers generators; and

c. The ventilating system provides excellent cooling for both stator and rotor.

(2) Low short-circuit ratio, which results in a machine that is sensitive to load changes and is likely to be very unstable when operated on a system with rapidly changing load. The application of voltage regulators is more difficult on account of the wide range of exciting current which is required for a given load change.

(3) The high armature leakage reactance, which is obtained from the additional slots, provides short-circuit protection and the additional reactance which is secured does not materially increase the core loss under stable load conditions. However, this method of obtaining high reactance involves an increase in cost and overall diameter, and 0.15 to 0.20 per cent reduction in generator efficiency.

C. J. Fechheimer: A few points of interest in this paper will be pointed out in this discussion.

1. The scheme of stator ventilation is unique, as the circumferential system is combined with the axial system. The air which flows circumferentially does not pass through the stator teeth and into the air gap, but the air that flows axially first flows radially inward and then axially through the leakage slots.

Referring to Fig. 2 you will notice that at the back of the core through which the air passes first axially to get into the radial slots, there are eight openings distributed about. The air passes down, radially, in the vent ducts and then, in the same vent ducts, some passes around circumferentially and goes out. Some of the air goes farther radially between the coils and gets into the leakage slots and then moves axially. You see that on one side are shown one kind of guide for the air and on the other side of the line, the guides are arranged differently. Now on the right side of the line, the guides are for the air coming in, and to the left they are for the air going out; that is, the air moves axially and then out, radially, in the next vent duct; and that is the one at 45 deg. to the left of the division line. It moves axially through the leakage slot.

It would seem that the objections which were raised to the circumferential system of ventilation are believed not to apply to Mr. Roth's machine.[1] In the tests on the model for circumferential flow described in my A. I. E. E. paper in 1924, the air flowed radially through the vents and then circumferentially through the air gap. Although an analytical study of Mr. Roth's system of ventilation has not been made, the low temperatures obtained and the comparatively small dimensions, indicate that the system is excellent. It would seem that the supply of air to the leakage slots is sufficient to maintain comparatively low temperatures in the tooth belt where the material is worked the hardest.

2. The method which Mr. Roth uses for measuring the losses and air volumes at full load is novel. Mr. Roth assures us that he can obtain accuracy by calibrating the system, operating idle as a synchronous motor with known total losses at two different voltages. In the equation on page 10, what is the order of magnitude of $\Delta t_2 - \Delta t^1$? I presume it is about 10 deg. cent. and to obtain accuracy these temperature rises must be measured with extreme care.

The measurement of the temperature rises of the air by means of resistance coils connected in a Wheatstone-bridge network is one that is frequently used, and if proper precautions are taken, it should lead to accurate measurements. With small temperature rises, it is necessary to measure resistances with extreme accuracy, as a one degree change in temperature corresponds approximately to only 0.4 per cent change in resistance; or, if the temperature rise is 10 deg., it is necessary to read to 0.04 per cent if the error is to be not over 1 per cent. In some of our work, temperature rises of the order of only two degree are obtained, and then it is necessary to read to 0.008 per cent. While, with extreme care, such measurements of resistance can be made, there are possible sources of error, such as those due to contact resistance or those which might arise from the stretching of some of the wires, and this introduction of considerable errors.

In the early work on air-volume measurements by the thermal method at the Westinghouse Company, resistance measurements were made, but they were abandoned partly because of the necessity for great precision in measurement and partly because a few of the wires stretched and the resistance was consequently changed. We have since been using large numbers of thermocouples connected in series, and, for the most part, have been able to secure very reliable results. We can read our volumes within about 1 per cent. Of course, if only a few thermocouples are used, this method is not recommended, as a reliable average is not then obtainable.

3. The volume of air through the rotor seems to be very high. In conversation Mr. Roth explained to me the method which he used for measuring it. I think that the method is of sufficient interest to warrant him telling the members of the Institute what it is.

4. The device shown in Fig. 14, for measuring the pressure of the cooling air, is a model of part of the machine in which the flows are imitated as accurately as possible. I should inquire of Mr. Roth how close the agreement was between the pressure measured in the model and the pressure measured in the machine. I am a great believer in imitating in a model, conditions in the actual structure; but in this, care must be exercised, as sometimes the conditions are extremely difficult to imitate with sufficient accuracy.

5. Mr. Roth states that with a salient-pole alternator, the self-excitation is synchronous. It may be of interest to those who have not noted it before that it is possible to increase the

1. *An Experimental Study of Ventilation of Turbo Alternators.* TRANS A. I. E. E., 1924, pp. 486-488.

load on a salient-pole alternator gradually when it is being excited by condensive reactance until, at a certain load, the alternator pulls out of step and runs at a speed slightly above the frequency of the line. In other words, in a salient-pole machine just as in a turbo alternator it is possible to have self-excitation and operate as an asynchronous generator. One of the oscillograms in the discussion referred to by Mr. Roth shows this very clearly.[2]

E. H. Freiburghouse: I agree in general with what Mr. Laffoon has said as to the principles governing the limit of electrical stability of alternators and I too question whether these generators which have been described by Mr. Roth possess the necessary margin of stability.

Nevertheless, Mr. Roth has informed me that generators having these characteristics do operate successfully and that the power-station people do not find it necessary to employ voltage regulators. He states that voltage regulators have been installed but their use has not been found necessary.

Some years ago, the General Electric Company rebuilt a large foreign-made, turbine-alternator in which they even increased the originally high synchronous impedance. There have always been doubts about the stability of that generator; however, it has now been operating satisfactorily for seven years although the excitation for synchronous impedance is 2.04 times that for normal voltage at no load. The above is an abnormal ratio which we do not advocate. Instead, we usually make the ratio less than unity.

The deep, partially closed, leakage slots which Mr. Roth has employed to increase the reactance, also inherently make it necessary to assemble the stator bars axially from the end of the core. Obviously, the fit of the coil cannot be so close in the slot as if it were inserted radially under pressure from the air gap or open end of a slot. However, his machine is much shorter than we are building for that output.

We do not believe that 27 per cent reactance is necessary to insure the safety of the turbine-type alternator which has its stator winding laced at the ends to supporting rings. This machine as built in America is apparently flexible and strong enough to withstand many thousand dead short circuits without permanent distortion of the end structure. I recently witnessed a number of dead short circuits upon generators rated 35,300 kv-a. upon which there was no permanent distortion whatsoever.

Referring to the heating of these generators as given by Mr. Roth in Table I, we find that the temperatures obtained during the open-circuit run No. III were fairly uniform throughout the core; however, this was not the case during the sort circuit test No. I. On tooth G, Fig. 15, the rise was 70 deg. cent.; on tooth F, 27 deg.; and on tooth E, 26 deg. G was in the second package of iron from the end of the core whereas the others were in the middle of the core. I venture to say that the extra heating of tooth G was caused by flux from the magneto-motive-forces of the stator winding outside of the core. We are interested to know what temperatures were obtained at the other end of the core by couples 1, 2 and 3.

W. B. Kirke: This paper brings out new methods of incorporating characteristics of high reactance without obtaining excessive armature reaction. At the same time the use of leakage slots provides an effective method to keep the temperature rise within low limits.

The first characteristic of high reactance is provided for in a great many systems in this country by the use of external reactors in the circuit connecting the generator to the bus. Such reactors not only aid in keeping the voltage near normal with a generator short circuit but they also reduce the interrupting duty on the generator circuit breakers. On the other hand, if the reactance is built into the machine by the use of leakage slots or other means, a generator short circuit means dropping the voltage of the bus section fed by that unit.

Increasing the stability of the machine is a very desirable feature. As systems are more extended and more power plants interconnected, one wonders if ever a condition will exist when the extreme ends of an interconnected system will start rocking, due to lack of stability of the interconnected system. Any measure tending to increase the stability of a single unit will aid in stabilizing a large system consisting of many such units.

The use of leakage slots would seem to indicate a considerable advantage in ventilating the unit. With the maximum size of turbo generators steadily increasing as the size of systems and interconnection facilities develop, capacities of 100,000 kv-a. will soon be required. Any method which indicates an improved means of ventilation should be given thorough analysis by designing engineers.

Robert Pohl: "The most interesting part of Mr. Roth's paper is his advocacy of leakage slots below the main stator slots. This design is for obvious reasons superior to the deep slot bridges advocated by Miles Walker many years ago, but somewhat similar in principle to the practise of some makers to use much deeper open slots than necessary for the winding. The author has convincingly demonstrated the advantages of his design. I should like to say, however, that the properties of such leakage slots do not appear to me generally advantageous but only in special cases. In the first place why employ so high a reactance as 27 per cent? If Mr. Roth's 60,000-kv-a. alternator had been made without leakage slots its reactance of 18 per cent would have been fully high enough for all ordinary requirements and perhaps already too high for stations with feeder reactances and a poor power factor. In Europe we have often to deal with station power factors much below 0.8 down to 0.6. In such cases the increase of reactance makes itself seriously felt in the size and to some extent in the efficiency of the alternator.

As to the author's comparison of the two methods of obtaining high reactance, leakage slots or increased electric loading, one misses the third alternative, i.e., a separate reactor. It is obvious that an alternator with separate reactor will as regards stability, auto-excitation and stresses on end connections, behave exactly as a corresponding alternator with leakage slots and equal total reactance. A short circuit on the alternator terminals need hardly be feared. It seems to me that the leakage-slot design with its appreciable increase in the stator dimensions is the more expensive way of creating the desired additional reactance. If so, it can only be justified by the remaining advantage, i.e., the improvement in ventilation. This seems to me the decisive point. Here one has to distinguish between bipolar and multipolar designs. In bipolar turbo alternators the output is mostly limited by the temperature rise of the rotor. The stator winding is generally cool enough when placed in the ordinary way in close proximity to the rotor. Hence there appears to be no cause for changing this practise. The same applies to smaller four-pole machines with solid rotors. In the larger four-pole and even more so in the six-pole designs with built-up rotors the ventilation of the latter is more effective and the limiting temperature may be found in the stator winding. Here it may well be advantageous to employ an otherwise unnecessary depth of slot or leakage slots after Mr. Roth's proposal if there is no other way of improving the ventilation.

Another way of improving the cooling of altenators is the use of hydrogen or other gases superior to air as cooling media.

Franklin Punga: I congratulate Mr. Roth on his contributions to developments in the design and construction of large turbo generators, and in particular on the means by which he was able to increase to 60,000 kv-a. the rating of the 45,000-kv-a. generator, without altering the external dimensions.

2. Trans. A. I. E. E., 1920, Vol. XXXIX, p. 1637.

Regarding certain features I should like to make the following observations:

I thoroughly endorse the employment of a stator slot provided with a large open portion at the end opposite the air gap. This is very useful for ventilation purposes. In the design which I some time ago proposed to the Thyssen firm, and contrary to the design of Mr. Roth, the lower third of the slot was widened as shown in the accompanying illustration of the slot, Fig 3. The principal reason for this relates to winding construction technicalities. In the normal partly or entirely closed slot, the conductor has to be inserted axially. This makes it necessary to make a relatively great allowance for clearance between the side of the slot and the insulated conductor, otherwise the insulation on the conductor is liable to be harmed in the process of being inserted into place in the slot. Should any repair of the winding ever be necessary it is exceedingly difficult to remove such a conductor from the slot. In designs in which the conductor is inserted radially into an open slot, it is practicable to allow less clearance between the insulated conductor and the sides of the slot. This is desirable for several reasons, such as (1) obtaining a better space factor, and (2) decreasing the liability to corona phenomena. When employing my design of slot the insulated conductor is first introduced axially into the space in the lower third and is then pressed radially

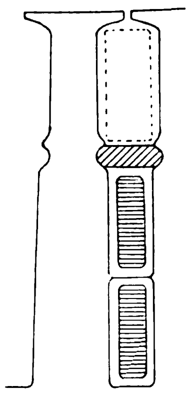

Fig. 3

upward into place, the space available in the ventilating ducts being convenient for the application of the necessary radial pressure.

But this design of slot fulfils a second important purpose. It is well known that if the tooth saturation is too great, the flux passing parallel to the sides of the slot occasions a considerable copper loss. For this reason it is customary to employ a relatively low no-load tooth saturation (some 16,000 lines per sq. cm.), so that at full load the value of 20,000 lines per sq. cm. shall not be exceeded. Now the difference between the tooth saturation at full load and that at no load is chiefly dependent upon the distorting ampere-turns. The decreased tooth section in the lower third of the slot consequently serves as insurance against too great saturation in the portions where the copper is located and will be found especially valuable in turbo generators with a cos near ϕ unity.

Furthermore the slot leakage is of course also decidedly increased, although not so much as in the case of the turbo generator designed by Mr. Roth. The advantages which Mr. Roth mentions, relating to relatively great slot leakage are all of them correct, but a disadvantage of the great slot leakage ought not to be overlooked, namely, the radial saturation of teeth at particular parts of the circumference on the occurrence of sudden short circuits. For instance if we represent the leakage of one slot by a vector, this will be of uniform magnitude and direction until we come to a place on the circumference where one phase winding is completed and the next phase winding begins. In a four-pole machine with two conductors per slot, and 100 per cent winding pitch, there are on the circumference twelve such places. The slot leakage vector moves through 60 electrical degrees and the consequence is that at these points a flux represented by a vector of equal magnitude passes through the tooth and into the laminations behind the slots. Consequently in such a machine at short circuit there would be complete saturation of twelve teeth equally distributed around the circumference. This would decrease the effectiveness of the great slot leakage. In this respect the use of fractional-pitch windings is of advantage since the number of these teeth is then increased from twelve to twenty-four so that the flux set up in each tooth is appreciably smaller.

Mr. Roth's observations about self-excitation have interested me very much. In German power houses it is now required that large polyphase generators shall be able to carry as leading load 80 per cent of their rating. This requirement has a close relation to the problem of self-excitation discussed by Mr. Roth. This problem will be of even more importance in the future if the lengths and voltages of transmission lines are increased.

In conclusion I should like to briefly mention that the principal progress which has been made in the development of large turbo-generators has been due to the avoidance of stray losses. These stray losses were due to (1) current distortion in the slot copper; (2) flux passing parallel to the slot sides and of too high tooth saturation; (3) flux passing from the field into the open slot; (4) variations in flux density around the circumference of the field, due to the slot openings; (5) the leakage flux from the end windings, (a) in the copper of the end windings, (b) in the end clamping parts (6) iron short circuits due to bad workmanship in slotting and assembling the cores.

From this paper of Mr. Roth's and from his previous publications it is very evident that the author has dedicated much study and research to the problem of decreasing the stray losses and of their exact measurement.

J. Rosen (communicated after adjourment): I would refer only to one section of Mr. Roth's paper in which he deals with the difficulty of alternator instability. It is sometimes forgotten that many of the difficulties lie in the excitation circuit. Some ten years' ago, instability was experienced on an 18,000 kv-a. alternator, operating at unity power factor and sometimes with a leading power factor. The alternator air-gap was increased, with entirely satisfactory results.

Later experience and tests on other plants showed that attention should also have been directed to the design of the exciter. One of the improvements adopted was the addition of a few series turns to the exciters, which overcame entirely the alternator instability difficulties which had up to that time, been experienced. The tests have proved that sudden changes. in load, faulty synchronising, and faults in the transmission line are reflected in the alternator rotor by momentary increases in the value of the rotor current. I would refer to the papers, and the discussions upon them, on "Exciter Instability" by R. E. Doherty[3] and "Some Problems In High-Speed Alternators and their Solution"[4] by the writer, in, which the whole problem is discussed in full.

Calculated figures are given by Mr. Roth of the total inherent reactance of the plant. It would be of interest to learn if they are confirmed by actual sudden-short-circuit tests at the normal operating voltage.

E. Roth: The most important observation presented in this discussion has been expressed by Messrs. W. F. Dawson, Philip Torchio, C. M. Laffoon, E. H. Freiburghouse and W. B. Kirke

3. Journal A. I. E. E., Vol. XLI, No. 10, p. 731.
4. *Journal* I. E. E., Vol. 61, No. 317, p. 452-3.

and regards the armature reaction to which American practise gives lower values than that which exists in our alternators.

Mr. Laffoon has given a very complete statement of this point and I am in general in agreement with him. His comments apply more particularly to the conditions of stability.

These machines were designed to run first at $41\frac{2}{3}$ cycles in parallel with the distributing system of Paris, and later at 50 cycles. In fact the machines have never been operated at $41\frac{2}{3}$ cycles. Moreover the customer wanted a very low value of instantaneous short-circuit current, of about four times the normal current, which condition had never been required before from large turbo alternators. It was therefore necessary to design a machine in accordance with these requirements without neglecting, of course, the condition of stability.

Four years' experience have shown that these machines have been giving entire satisfaction to the users. Had difficulties arisen with regard to stability, it would have been easy to enlarge the air-gap of these machines sufficiently, without exceeding the standard American temperature rise of 90 deg. cent., which up to the present has never been attained in our machines.

These machines have been designed for 35,000 kw. at 80 per cent power-factor, that is 43,750 kv-a.; in fact, they are operated at 40,000 kw. and 50,000 to 55,000 kv-a.

Based upon this experience the 60,000-kv-a. machines have been built on the same principles but the flux has been increased slightly and the air-gap enlarged to maintain the same conditions of stability. Considering the operating conditions we are confident that they will run as satisfactorily as the former, and should difficulties arise these could be easily remedied.

As pointed out by Messrs. Torchio, Kirke and Pohl, the low value of the instantaneous short-circuit current could have been obtained by reactance coils. This solution was examined very seriously but had to be rejected. Indeed, these reactance coils are very cumbersome and the price of the alternator together with reactance coils, has been found higher than that of the alternator with leakage slots alone. The efficiency using reactance coils is less than with the solution adopted; first it is not possible to build reactance coils with a loss smaller than 0.15 to 0.20 per cent and further when external reactance coils are used the alternator has to be operated at a higher terminal voltage, which creates core losses which do not exist in the case of leakage slots.

With regard to operation the use of reactance coils or of leakage slots leads exactly to the same result. Whenever it is desired that the voltage drop at the busses on short-circuit be not too high, individual reactance coils should be installed on every feeder.

I wish to emphasize what I have already stated in my paper, that using leakage slots in a given machine does not practically alter the conditions of stability; thus should a customer require from American manufacturers as small an instantaneous short-circuit current as in the Gennevillier's machines, they could obtain it, without changing any of the properties of their machines, by simply adding leakage slots.

I greatly appreciate the technical progress which the American manufacturers have obtained by designing their 62,500-kv-a. turbo-alternator for 1800 r. p. m. I know very well the difficulties which they may have encountered and I think that this is still a more marked progress than that which the Socéité Alsacienne has made when they built their 45,000-kv-a. alternators for 1500 rev. per min., which capacity was at that time only realised at 1200 and 1000 rev. per min. I have learned with great interest that Mr. Laffoon sees the possibility of constructing 75,000-kw. machines at 90 per cent power-factor and 1800 rev. per min. In Europe we think that it is possible to build 50-cycle turbo alternators for over 100,000 kv-a. at 1500 rev. per min. and for 40,000 kv-a. at 3000 rev. per min.

NEW CORRUGATED BULB AIDS IN THE PREVENTION OF AUTOMOBILE HEADLIGHT GLARE

The introduction of the corrugated automobile headlight bulb is an important step in the more exact and complete control of the beams from headlights toward which various refinements in the manufacture of the several elements of the equipment are contributing.

Glaring headlights which so greatly detract from both the pleasure and safety of night driving, result for the most part, first, from failure to properly focus and aim the headlamps, and second, from the limitations of a fixed-beam system on any except smooth, level roads. Considerable effort is being put forth to bring about better headlight adjustment and depressible-beam equipment, using the new two-filament headlight lamp, overcomes the limitations which are inherent in a fixed-beam system.

There is a third though lesser source of glare which

A B

Fig. 2—(a) Cross Section of a Beam of Light from a Parabolic Reflector with a Lamp having a Smooth Bulb from which an Image or Secondary Light Source is formed as in Fig. 1 a.

(b) Cross Section of the Beam of Light when the Image or Secondary Light is Eliminated

is found even with properly focused and aimed good equipment. It is the secondary source or filament image which is formed in a headlight by the rays reflected from the inner surface of the spherical part of the bulb. The filament is at the center of this hemisphere and hence, when it is exactly placed, the image is superimposed on the filament. Actually, there is frequently a slight displacement from this exact position, in which case the image is off-set as illustrated in Fig. 1a. The brightness of this image, or secondary source, may be as much as five per cent of that of the

filament. The equipment, adjusted for the main source, will then direct the secondary beam from the image at a different angle, as indicated in Fig. 2A, and often this will be toward the approaching driver's eyes, causing him annoyance. When the spherical surface is broken up with corrugations, the reflected rays are dispersed sufficiently to avoid the formation of a definite image, as in Fig. 1B, and the resulting secondary beam.

The corrugations on headlight bulbs were not placed there to add a novelty feature, but represent the result of a long and successful search for the best means of avoiding glare from source images in the bulb.

COST AND STANDARD OF LIGHTING

Assuming no decrease in the purchasing power of money, as much light can be purchased today for one or two cents as could be bought a century ago for one dollar. But unfortunately our dollar has had many shrinking moods during this period, and this must be taken into account in any comparison of lighting standards with those of a century ago. For the sake of comparison let it be assumed that the purchasing power of gold is only one-third as great today as it was one hundred years ago. If the use of light were keeping pace with the efficiency of light production, the workman would be supplied with three hundred times more light than he then had. But the standard of working conditions has also greatly altered. If it be assumed that this has increased about five times, the workman today should be supplied with about fifteen hundred times more light than he had a hundred years ago.

If the workman in that age of candles had an intensity of illumination of two-thirds of a foot-candle, he should have a thousand foot-candles today, if the use of light is to keep its proper pace. Of course, light is more generally distributed now in a well-lighted factory than was the case in those earlier years. The workman benefits by this better condition, but the fact remains that the actual artificial illumination under which he works is only a few times that enjoyed by his predecessor of a century ago. It is known that the best intensity of illumination for general work is of the order of magnitude of a thousand foot-candles, and on the basis of the foregoing assumptions the workman is entitled to it. If not satisfied with the assumptions, anybody may reduce them as he sees fit. Even the most radical scaling down would leave us with a hundred foot-candles or more. Then why is the workman not supplied with this amount at least? Here is a question that the reader may find it interesting to attempt to answer.—*Electrical World.*

THE SOLUTION OF A RESIDENCE STREET LIGHTING PROBLEM

Engineering, perhaps more than any other profession, has many precepts and fundamental principles upon which there can be no differences in opinion among the members of the profession. Nevertheless, there are certain phases of this field of science in which the opinions and specifications sponsored by different engineers, may be as widely diversified as the diagnoses of a particular medical case by several physicians. It is only natural to expect that such a condition may frequently be encountered in any line of endeavor inasmuch as the realm of man's absolute knowledge is limited, consequently a thorough interchange of ideas on any problem upon which there is likely to be a diversity of opinion is nearly always advantageous to those concerned with its solution. As elsewhere, this is quite true in illuminating engineering as has been shown by the advances which have been made in this field during recent years.

Among the commercial applications of artificial lighting there have been few upon which there has been such a diversity of opinions as on the requirements and specifications of proper street lighting. In view of this fact the Illuminating Engineering Society has, at some of its past meetings, chosen the symposium* form of discussion for this subject. Sometime in advance of the actual meeting a typical street lighting problem was selected and a blueprint layout and photograph of a definite residential street were sent, together with a questionaire, to a number of illuminating engineers who were more or less concerned with the design of street lighting installations. A summary of the solutions for lighting this section of a residence street, obtained from these engineers is given in the accompanying table in a manner which shows very readily the similarities and differences in the different designs.

The consensus of opinion seems to favor a series, underground distribution system, operating at 6.6 amperes with a staggered arrangement of units, for a residential street in a city of 100,000 such as the one under discussion in this particular case. There is, of course, a variance in the recommended costs per mile for the different solutions but even such differences in cost estimates are not as great as they probably would have been ten years ago, because engineers are now more fully agreed as to what constitutes reasonably adequate street lighting. With one exception, the recommended mounting heights are included in the comparatively small range of 11 to 16 ft. and an ornamental unit is specified.

At present, there seems to be no thoroughly satisfactory method of comparing illumination values on city streets. However, by measuring these values in terms of lumens per foot there is at least some indication as to the total amount of light which is available. Using this method of measurement we find that these different solutions vary from 13 to 50 lumens per foot in their recommendations.

This general method of treating the street lighting problem seems likely to crystallize our ideas regarding practise and so not only advance the art but also tend toward the establishment of definite styles. The great value comes from the opportunity of summing up and comparing the ideas of various engineers.

*Discussion before the Annual Convention of the A. I. E. E. at Detroit, September, 1925.

THE SOLUTION OF A RESIDENCE STREET LIGHTING PROBLEM

Solution No.	Cost per Mile per cent of Average	Illumination values	Size of Incandescent Lamps Lumens	Amp.	Arrangement of Lamps	Spacing Ft.	Fixture	Standard	Bracket	Mounting Height Ft.	Distribution System

The 1926 Midwinter Convention

A LARGE PROGRAM OF IMPORTANT TECHNICAL PAPERS WAS DISCUSSED AT WELL-ATTENDED SESSIONS

The fourteenth Midwinter Convention of the American Institute of Electrical Engineers, held February 8-11, 1926, maintained the tradition of its predecessors in their constantly growing importance, in the increasing number of members and guests in attendance, and in the character of the papers presented and discussed. Of all the Institute meetings, the Midwinter Convention is preeminently the working convention of the year, at which entertainment is largely subordinated to the consideration of the most technical professional problems, and the attendance this year of over 1500 members attests the worth of these conventions to the electrical profession. The entertainment features, consisting of a Smoker Tuesday evening, a Dinner-Dance Wednesday evening and two instructive popular lectures Thursday evening were well patronized and greatly enjoyed. The heaviest snowfall in several years occurred at the time of the convention and for several days almost paralyzed vehicular traffic, but despite this handicap the visits of inspection to numerous engineering establishments in and about the city of New York with few exceptions were carried out according to schedule. Monday morning was devoted to registrations of members and guests and to several committee meetings. At such intervals as occurred between the technical sessions, other committee meetings were held from time to time during the convention week.

MONDAY AFTERNOON

Technical Session

The opening session of the convention convened at 2.30 p. m. in the Engineering Auditorium and was called to order by President Pupin, who extended heartiest greetings to the members assembled. He then introduced Percy H. Thomas, Chairman of the Transmission Committee, who conducted the Transmission Session which followed.

The general subject of the first session was Stability on Transmission Lines and for the benefit of those who were not entirely familiar with the subject of stability on transmission lines, Mr. Thomas gave a brief general explanation of the subject.

The first four papers of this session were presented and discussed together as their subject matter was closely related. The first paper, *Investigation of Transmission-System Power Limits*, by C. L. Nickle and F. L. Lawton was presented by Mr. Nickle. Chairman Thomas then called for the second paper, *Calculation of Steady-State Stability in Transmission Lines*, by Edith Clarke, Miss. Clarke abstracted her paper. The third paper entitled, *Practical Aspects of System Stability*, by Roy Wilkins was abstracted by Mr. Wilkins and the fourth paper, *Further Studies of Transmission Stability*, by R. D. Evans and C. F. Wagner was abstracted by Mr. Evans.

In the extended discussion which followed on this group of papers, remarks were made by R. D. Evans, H. W. Smith, H. H. Dewey, H. H. Spencer, H. K. Sels, R. E. Doherty, C. L. Fortescue, H. B. Dwight, J. W. Legg, Svend Barfoed and Mr. F. L. Lawton read a written communication by L. F. Woodruff. The discussion was closed by C. A. Nickle, Edith Clarke, Roy Wilkins and C. F. Wagner.

Chairman Thomas next called for the presentation of the last paper *Transmission Stability with Over-Compounded Voltages*, by H. B. Dwight, this was abstracted by the author. The paper was then discussed by C. B. Christie and a written discussion from L. F. Woodruff was read.

MONDAY EVENING

Technical Session

The next session of the convention convened at 8.15 p. m. and was called to order by E. B. Meyer, Chairman of the Meetings and Papers Committee. Mr. Meyer announced the subject of the evening was dielectrics and insulation. Three papers were scheduled for this session under the auspices of the Committee on Electrophysics and J. H. Morecroft, Chairman of that committee presided at the meeting.

Chairman Morecroft announced that each author would be allowed fifteen minutes to abstract his paper and that the three papers would be read in succession and then discussed together. The first author called upon by Chairman Morecroft was J. B. Whitehead, who abstracted his paper on *Dielectric Absorption and Theories of Dielectric Behavior*. The next paper, *The Theory of Absorption in Solid Dielectrics*, by V. Karapetoff was also summarized by the author. The next paper of the evening by C. L. Dawes was *Ionization Standards in Paper-Insulated Cables*. This too was abstracted by the author.

Extended discussion participated in by A. E. Kennelly, H. B. Smith, E. W. Davis, W. A. Del Mar, R. E. Marbury, R. W. Atkinson, E. S. Lee, E. W. Roper, W. B. Kouwenhoven, J. Slepian, W. F. Davison, George B. Shanklin, S. L. Gokhale and C. A. Adams followed the presentation of these three papers. Closures were made by Messrs. Whitehead, Dawes and Hoover.

TUESDAY MORNING

Technical Session

The Tuesday morning session on Protection, Control and Bus Construction was under the auspices of the Committee on Protective Devices with F. L. Hunt presiding. The following

papers were presented in abstract by their authors: *Operating Performance of a Petersen Earth Coil*, by J. M. Oliver and W. W. Eberhardt, (presented by Mr. Oliver); *Theory of Auto-Valve Lightning Arresters*, by Joseph Slepian; *Current Limiting Reactors with Fire-Proof Insulation on the Conductor*, by F. H. Kierstead; *Temperature Rise and Losses in Structural-Steel Members Exposed to the Fields from A-C Conductors*, by O. R. Schurig and H. P. Kuehni, presented by Mr. Schurig; *Carrying Capacity of Sixty-Cycle Busses for Heavy Currents*, by Titus G. Le Clair and *Supervisory Systems for Electrical Power Apparatus*, by Chester Lichtenberg.

The following members took part in the discussion: K. B. McEachron, H. B. Dwight, V. M. Montsinger, S. I. Oesterreicher, C. E. Stewart, C. F. Wagner, R. G. Weiser, H. C. Forbes, A. E. Kennelly, L. P. Ferris, H. L. Wallau, W. W. Eberhardt and Joseph Slepian.

Tuesday Afternoon

Technical Sessions

Parallel sessions were held on Tuesday afternoon; Session A, on Electrical Machinery, convened in the Engineering Auditorium and Session B, on Communication and Sound Reproduction, in the fifth floor assembly room.

Session A was under the auspices of the Electrical Machinery Committee and was called to order by E. B. Meyer, who requested H. M. Hobart, Chairman of the Electrical Machinery Committee, to take charge of the meeting. Chairman Hobart called on the authors of the following papers to abstract their articles, which were subsequently discussed. The papers presented were: *Experimental Determination of Losses in Alternators*, by Edouard Roth (presented by E. H. Freiburghouse); *No-Load Copper Eddy-Current Losses*, by Thomas Spooner; *Mechanical Forces Between Electric Circuits*, by R. E. Doherty and R. H. Park; *Ventilation of Turbo-Alternators*, by C. J. Fechheimer and G. W. Penney.

The discussion which followed was by Messrs. W. F. Dawson, B. L. Barns, S. L. Henderson, Joseph Slepian, W. J. Foster, C. J. Fechheimer, E. H. Freiburghouse, with closures by R. E. Doherty and E. H. Freiburghouse.

Session B was called to order by H. P. Charlesworth, Chairman of the Committee on Communication, under whose auspices the session was held. Chairman Charlesworth announced that as the program of papers was diversified in character, the session would take up each subject, followed directly by its discussion.

The first paper on the program was *The Development and Application of Loading for Telephone Circuits*, by Thomas Shaw and William Fondiller and was presented by Mr. Shaw. The paper was discussed by F. B. Jewett, W. L. Smith, M. I. Pupin, with closure by William Fondiller.

The next paper on the program called for by the Chairman was entitled *Cipher Printing Telegraph Systems*, by G. S. Vernam, and was discussed by L. F. Morehouse and Paul W. Evans. This paper was followed by one on. *Refraction of Short Radio Waves in the Upper Atmosphere*, by W. G. Baker and C. W. Rice, presentation being made by Mr. Rice. The discussion which followed was by A. E. Kennelly and W. B. Kouwenhoven with closure by W. G. Baker.

The final paper in the session was presented by its author, J. B. Maxfield and was entitled *High-Quality Recording and Reproducing of Music and Speech*. At the close of the presentation a demonstration of the audiophone was given and a comparison between this and the older style of phonograph was shown. The paper was discussed by C. R. Hanna, H. B. Marvin, E. W. Kellogg, A. E. Kennelly and closure was by J. P. Maxfield.

Tuesday Evening

Smoker

Tuesday evening was devoted to a Smoker at the Hotel Astor at which about one thousand men were present, filling the Belvedere Room to capacity. The entertainment which was furnished by the New York Section consisted of moving pictures, an excellent male quartet, an interesting slight of hand performance, including an explanation of some tricks frequently employed at spiritualistic seances, together with popular music by an excellent band. A buffet supper was served toward the close of the evening and the informal but thoroughly enjoyable performance was fully appreciated by all who were present.

Wednesday Morning

Technical Session

The session on Wednesday morning was under the auspices of the Electrical Machinery Committee and Mr. H. M. Hobart, Chairman of that Committee presided.

The first paper was presented by Professor Karapetoff on the subject of *Parameters of Heating Curves of Electrical Machinery*. This paper was discussed by G. E. Luke, F. H. Kierstead, W. F. Dawson, C. J. Fechheimer and the discussion was closed by Professor Karapetoff.

The next paper was on the *Rating of Electrical Machinery as Affected by Altitude*, by C. J. Fechheimer and was abstracted by the author. This was discussed by R. E. Doherty, P. L. Alger, Earl B. Paxton, E. B. Dawson and W. F. Dawson, with closing remarks by Mr. Fechheimer.

The next paper, on the subject of *Motor Band Losses*, by Thomas Spooner, was presented in abstract by the author. It was discussed by G. E. Luke and J. F. Lincoln.

The final paper of the session, *Starting Characteristics of Polyphase Squirrel-Cage Induction Motors and Their Control*, was presented by its author, H. M. Norman, and was discussed by Professor B. B. Bailey, with closure by Mr. Norman.

Wednesday Afternoon

Inspection Trips

Wednesday afternoon was set aside for numerous inspection trips to the prominent engineering works in New York and vicinity, all being generously thrown open to the inspection of members of this Convention. The bus service, which had been provided to carry many of the visitors to the points of inspection, was necessarily cancelled on account of the snowbound condition of the streets, but many parties were organized, making the trips by either public or private conveyances.

Wednesday Evening

Dinner-Dance

The annual Dinner-Dance at the Hotel Astor which has become an invariable feature of the Midwinter Convention was held on Wednesday Evening, and as usual proved to be a most pleasing and enjoyable function. The dinner was attended by between six and seven hundred people and the music during the dinner and for the dancing was furnished by Paul Whiteman's Picadilly Players.

The evening was a thoroughly enjoyable one and the dancing continued until an early hour.

Thursday Morning

Technical Session

The session on Thursday morning was devoted to subjects of Electromagnetism and Physics and was held under the auspices of the Electrophysics Committee, J. H. Morecroft, Chairman, presiding.

The first paper announced by the chairman was *Calculation of Magnetic Attraction*, by Th. Lehmann. This paper, which had been translated by C. O. Mailloux was also abstracted by him. The next paper presented was by Hans Lippelt on the subject of *The Magnetic Hysteresis Curve* and was presented by the author. The third paper of the session by Carl Hering, entitled, *Properties of the Single Conductor* was next presented by Dr. Hering. The final paper, *Heaviside's Proof of His Expansion Theorem* was then presented by its author, M. S. Vallarta.

At the close of the presentations Chairman Morecroft called

for the discussion of the papers in their regular order. The discussion which followed was by Joseph Slepian, S. L. Gokhale, S. L. Quimby, M. F. Skinker, R. H. Park and J. J. Smith. Closures were made by Dr. Mailloux, Mr. Lippelt and Dr. Hering.

THURSDAY AFTERNOON

Technical Session

The final technical session of the Convention was held Thursday afternoon under the auspices of the Committee on Instruments and Measurements, with William A. Del Mar presiding.

Five papers were presented at this session, the first three presented and discussed being as follows:

A New Wave-Shape Factor and Meter, by L. A. Doggett, J. W. Heim and M. W. White; presented by Mr. White. *Practical Application of Vibration Instruments to Rotating Electrical Machines*, by J. Ormondroyd and *A High-Frequency Voltage Test for Insulation of Rotating Electrical Machinery*, by J. L. Rylander.

After these papers had been presented in abstract, a discussion followed by Messrs. J. J. Smith, C. T. Weller, V. M. Montsinger, C. E. Lee, W. B. Craigmile, F. K. Brainard, C. W. Bates, and G. E. Luke, followed by closures by Messrs. Doggett, Ormondroyd and Rylander.

The second group of papers at this session was presented as follows:

The Cross-Field Theory of Alternating-Current Machines, by H. R. West and *Rating of Heating Elements for Electric Furnaces*, by A. D. Keene and G. E. Luke. These were discussed by P. L. Alger, K. L. Hansen, and Joseph Slepian. The closures were by Mr. West and Mr. Luke.

This completed the technical program of the Convention.

THURSDAY EVENING

Illustrated Lectures

The Convention convened Thursday Evening at 8.15 p. m. in the Engineering Auditorium to hear two illustrated lectures by Dr. Alexis Carrel, and Major Allen Carpe.

Dr. Carrel, who is a member of the Rockefeller Institute for Medical Research, gave a lecture illustrated with motion pictures showing the life of tissues outside of organisms. The pictures showed the actual growth of living cells under artificial conditions, some strains of which in Dr. Carrel's laboratory have been living and growing since 1912.

Major Allen Carpe, a Fellow of the Royal Geographical Society, described and showed motion pictures of the Ascent of Mount Logan, the highest peak in Canada which is 19,850 feet in height. Some remarkable motion pictures were shown, covering the actual climb, hand sledding over the lower glaciers, the higher levels of the mountains and pictures of the party on the summit.

Both of these lectures were highly entertaining as well as instructive and were received with hearty applause.

ACKNOWLEDGMENTS

Credit for this most successful Convention is due to the excellent work of the committees in charge of the various features of the meetings. The Meetings and Papers Committee is to be congratulated upon providing the valuable program of technical papers. The entertainment features which were provided by the New York Section were of very high class and most appropriate. The excellent general arrangements and conduct of the entire Convention was due to the efficient work of the various Convention Committees, the personnel of which was as follows:

General Committee: H. A. Kidder, Chairman: H. H. Barnes, G. L. Knight, E. B. Meyer and L. F. Morehouse.

Entertainment Committee: H. H. Barnes, Chairman: G. W. Alder, J. B. Bassett, H. Y. Hall and H. S. Sheppard.

Dinner-Dance Committee: J. B. Bassett, Chairman: A. F. Dixon, E. E. Dorting, C. R. Jones, J. F. Kelly, F. A. Muschenheim and R. A. Paine, Jr.

Smoker Committee: G. W. Alder, Chairman: H. B. Coxhead, R. R. Kime, E. C. Soares, S. B. Williams, Jr. and C. V. Woolsey.

Inspection Trips Committee: H. Y. Hall, Chairman: C. M. Gilt, I. W. Green, G. C. Hall, R. R. Kime, J. T. Lawson and G. H. Stickney.

Special Meeting Committee: H. S. Sheppard, Chairman: L. W. W. Morrow and J. W. Walters.

Finance Committee: G. L. Knight, Chairman.

Regional Meeting at Cleveland March 18-19

The Cleveland Regional Meeting arranged by the Middle Eastern District of the Institute will be held on March 18 and 19 with headquarters at the Hotel Cleveland. An attractive program will be presented including papers on sectionalized electrical drive, domestic refrigeration, engineering and humanity, and lighting. On Thursday, March 18, a dinner will be given at which the Honorable Newton D. Baker will make an address. Another feature will be a visit to Nela Park. Details of the program are given below.

SECTIONAL ELECTRIC DRIVE

Thursday morning and afternoon will be devoted to papers and discussion on sectional electric drive. Engineers in a number of industries will be interested in this subject, for although this synchronized group type of drive was developed primarily for application to paper machines, it may now be applied to any driven apparatus where the conditions require a fixed angular relation between the different sections of the machine and where the advantages to be gained warrant the investment. It may well be considered in such applications as are found in the steel mill, the baking plant, the textile finishing plant, or in the rubber mill.

The regional dinner will be held Thursday evening and Friday evening will be spent at Nela Park of the National Lamp Works of the General Electric Company. An unusual program has been arranged, during which the magic of light will be portrayed by striking demonstrations.

Opportunity will be afforded also to make inspection trips to other Cleveland industries at the pleasure of the members.

A luncheon meeting for Counselors of Student Branches of the District has been scheduled for Friday noon.

A very enthusiastic group of committee members has made arrangements for this meeting; lack of space prohibits the publishing names other than the various chairmen who are as follows: A. G. Pierce, Vice-President of Middle Eastern District; A. M. MacCutcheon, General Chairman; G. A. Kositzky, Finance; H. B. Dates, Program; L. D. Bale, Transportation; I. H. Van Horn, Trips; A. M. Lloyd, Registration; C. N. Rakestraw, Dinner; H. L. Grant, Publicity; C. L. Dows, Reception, and E. H. Martindale, Attendance.

PROGRAM OF CLEVELAND MEETING

THURSDAY MORNING

Registration

9:45 A. M. Welcome, A. G. Pierce, Vice-President, A. I. E. E.

10:00 A. M. Technical Session: A. M. MacCutcheon, Chairman

Electrification of Paper-Making Machines, S. A. Staege, Westinghouse Electric & Mfg. Co.

This paper outlines the several trends of development in a historical sketch. It devotes special attention to a unique system of direct-current drive in which the section driving motors through a differential electrical field-control means, are caused to operate in synchronous relation at any desired relative speed values, which speed relations are at the same time adjustable at the will of the operator.

The Development of the Sectional Paper-Machine Drive, H. W. Rogers, General Electric Company.

In this paper the author deals with the history and development of the sectional drive as furnished by the company with which he is connected, and the relative merits of each particular type. The operation of sectional drives is explained.

THURSDAY AFTERNOON

2:00 P. M. Technical Session: A. M. MacCutcheon, Chairman.

Sectional Paper-Machine Drive, R. N. Norris, Harland Engineering Co.

This paper describes the type of control for sectionalized electric drive which has most generally been used in Europe and in Canada, and which has recently been successfully introduced into the United States. It tells of results secured particularly on very high-speed paper machines. The speed of each section motor, is referred to a master control speed through a simple mechanical differential.

THURSDAY EVENING

7:00 P. M. Regional Dinner, Hotel Cleveland.
Address by Honorable Newton D. Baker.

FRIDAY MORNING

9:45 A. M. Technical Session: Chester L. Dows, Chairman.

Some Scientific Phases of Refrigeration, Charles F. Kettering, President, General Motors Research Corporation.

(1) A comparison of the problems of the household and small commercial refrigeration with those of the large commercial type; (2) a description of the various types of refrigerating mechanisms; (3) the analyzing of many possible refrigerants; (4) an explanation of the reason for the development of special electric motors for this small refrigeration work; (5) the unusual requirements of producing, selling and servicing large quantities of these smaller refrigerators.

FRIDAY NOON

12:30 P. M. Luncheon Meeting of Branch Counselors.

FRIDAY AFTERNOON

2:00 P. M.—Technical Session, Chester L. Dows, Chairman.

Domestic Refrigeration from the Central-Station Point of View, George E. Miller, Cleveland Electric Illuminating Co.

Possibilities of this device as a load builder and its effect on the earnings of central-station companies. The return per kilowatt of demand, load factor, power factor. Illustrated.

Engineering and Humanity, Farley Osgood, Consulting Engineer, Past-President, A. I. E. E.

FRIDAY EVENING

Meeting at Nela Park

8:00 P. M.—Lighting Session, at Nela Park.

Nela Park, Its Organization and Objectives, R. W. Shenton, National Lamp Works, General Electric Company.

Recent Developments in Lighting, Ward Harrison, National Lamp Works, General Electric Company; Past-President, Illuminating Engineering Society.

Inspection Trips: Through Lighting-Research Laboratories; Historical Rooms; War-Trophy Exhibit; Industrial; Automobile and other Demonstrations.

SATURDAY MORNING

Inspection Trips: Inspection trips will be arranged to places of interest at the wishes of those attending the meeting.

Regional Meeting at Madison May 6-7

A two-day Regional Meeting will be held by the Great Lakes District of the Institute in Madison, Wisc., on May 6 and 7. Some very timely topics are on the program for discussion including rural electrification, transmission and distribution, cooperation in research between colleges and industries and radio interference. A number of foremost authorities will give papers or addresses on these subjects.

The committee in charge of the meeting consists of: Chairman, Edward Bennett, Vice-President of Great Lakes District; J. B. Bailey, A. G. Dewars, H. R. Huntley, L. E. A. Kelso, Carl Lee and R. G. Walter.

PAPERS AND ADDRESSES FOR MADISON REGIONAL MEETING

Rural Electrification, by Grover C. Neff, Wisconsin River Power Co.

Important Features of a Successful Plan for Rural Electrification, by George G. Post, Milwaukee Electric Railway and Light Co.

The Quality Rating of High-Tension Cable, by D. W. Roper, Commonwealth Edison Co.

Tests on High-Tension Cable, by F. M. Farmer, Electrical Testing Laboratories.

The Effect of Internal Vacua on Cable Operation, by W. A. Del Mar, Habirshaw Electric Cable Co.

Some Interconnected-System Operating Problems, by Frank G. Boyce, Consumers Power Co.

Cooperation Between the Colleges and the Industries in Research, Papers or addresses by:

Wm. E. Wickenden, Society for the Promotion of Engineering Education.

Dean A. A. Potter, Purdue University.

Benjamin F. Bailey, University of Michigan.

Edward Bennett, University of Wisconsin.

Behavior of Radio Receiving Systems to Signals and to Interference, by L. J. Peters, University of Wisconsin.

Regional Meeting at Niagara May 26-29

A three-day Regional Meeting will be held in Niagara Falls, N. Y., on May 26-28, by the Northeastern District of the Institute. Many interesting papers are scheduled for the meeting and the recreational activities are being carefully arranged.

The technical subjects to be discussed include dielectric power-factor measurement, insulation, transmission, power-plant tests, machinery, rectifiers, speed measurements, and others.

The entertainment features have been planned as follows: On Thursday afternoon, May 26, there will be a trip down the Niagara Gorge with stops at various points of interest and inspections of the power plants on both sides of the river. On Thursday evening will be the convention dinner and a number of Institute officers will make short addresses after which will follow a lecture of general interest to ladies and men. Late in the evening if it can be arranged the Falls will be specially illuminated. On Friday evening there will be a lecture or entertainment or possibly a motion picture.

Details of the program will be published in later issues of the JOURNAL.

Future Section Meetings

Baltimore

Mechanical Power and Trend of Civilization, by C. E. Skinner, Westinghouse Electric & Mfg. Co., Engineers' Club. March 19, 8:15 P. M.

Talk by a Member of the Local Section, Engineers' Club. April 16, 8:15 P. M.

Connecticut

Power Production. Hartford. March 9.
Illumination. Norwich. March 19.
Bay of Fundy. New Haven. April 9.

Lehigh Valley

Automatic Control of Centrifugal Pumps, by Otto Haentjens, Barrett Haentjens & Co., and

Wallenpaupack Hydro-Electric Development, by N. G. Reinecker, Pennsylvania Power & Light Co. Wilkes-Barre. March 26.

Oil Switches, by George A. Burnham, Condit Electric Mfg. Co., and

Horsepower, by John J. Johnson, Westinghouse Electric & Mfg. Co. Hazelton. April 23.

Pittsfield

Round-Table Discussion. March 9.

St. Louis

Development of Electric Power Generation and Distribution, by Col. Peter Junkersfeld, President, McClellan & Junkersfeld. March 17.

Automatic Stations, by C. A. Butcher, Westinghouse Electric & Mfg. Co. April 21.

Coming Plenary Meeting of International Electrotechnical Commission

Preparations are now well advanced for the meeting of the International Electrotechnical Commission to be held in New York in April. This Commission, which is an international standardizing body in the electrical industry, was organized in 1906 following suggestions made at the Electrical Congress held in St. Louis in 1904. Despite its many years of activity it has never held a meeting in this country, the reason for this being the intervention of the war. The meeting in New York will be the first one which has been held with full representation of all the countries which were active in the Commission prior to the war.

Plans for the meeting, in so far as they have been formulated, are as follows:

European delegates will arrive on *S. S. Andania*, due in New York on April 11th. Hotel arrangements are being made through the U. S. National Committee; the hotel headquarters will be the Hotel Astor. The meetings will be held in the Engineering Societies Building, 29 West 39th Street, New York, N. Y. The greater part of the activities of the Commission will center about the meetings of the various Advisory Committees of the Commission, which Advisory Committees are organized to formulate the work in particular fields and to report their results to the Plenary Meeting of the Commission. The preliminary schedule of the meetings is given in the following table:

Particular attention should be directed to the general meeting which is to be held in the Engineering Auditorium on the evening of April 13th. It is proposed that this meeting shall be conducted under the auspices of the engineering and technical societies which support the work of the U. S. National Committee and that the membership of these Societies shall be invited to attend this meeting. The meeting will be addressed by notable engineers from foreign lands and the work and purpose of the International Electrotechnical Commission will be set forth by them. The preliminary list of delegates indicates that amongst those present will be Sir Richard Glazebrook, K. B. E., Chairman, British National Committee, Sir Archibald Denny, Bart., Chairman, British Engineering Standards Association, Prof. C. Feldmann, President, Dutch Electrotechnical Committee, Professor P. Strecker, President, German Electrotechnical Committee, Mr. E. Huber-Stockar, President, Swiss Electrotechnical Committee, together with Signor Guido Semenza, President of the International Electrotechnical Commission. The preliminary list gives the names of 55 delegates from Europe; Norwegian, Russian, Polish, Spanish, French, Belgium, German, British, and Swiss, the German, British and Swiss delegations being particularly strong numerically. It is expected that later accessions will bring the list up to about 100.

In connection with the meetings in New York, there will be a number of entertainment features offered to the visiting delegates and at the close of this meeting, a tour will be offered which will include Philadelphia, Washington, Pittsburgh, Chicago, Detroit, Niagara Falls, Ottawa, Montreal, Boston, Schenectady and New York. The Canadian National Committee, which is cooperating in this enterprise will welcome the delegates at Niagara Falls and will conduct them to Montreal, where it is expected that a public meeting will be held in their honor.

The delegates will be received in various cities by local committees who will attend to making their stay at these places both profitable and enjoyable.

It may be noted that the first President of the I. E. C. was Lord Kelvin, and that Professor Elihu Thomson was President in 1911 at the time of the meeting in Turin. Dr. C. O. Mailloux is Junior Past-President and the Honorary President of the Commission. The President of the U. S. National Committee is Dr. C. H. Sharp and the Secretary is Mr. F. V. Magalhaes. The Chairman of the Reception Committee for the foreign visit is Mr. John W. Lieb, who is associating with himself a number of those most distinguished in the electrical industry.

Arrangements for the entertainment in New York are in the hands of Mr. F. W. Smith, of the United Electric Light & Power Company, and arrangements for the tour are being perfected by Mr. C. E. Skinner of the Westinghouse Electric & Manufacturing Company.

PRELIMINARY PROGRAM
PLENARY MEETING AND ADVISORY COMMITTEES OF I. E. C.

Time	Tuesday, 13th.	Wednesday, 14th.	Thursday, 15th.	Friday, 16th.	Saturday, 17th.	Sunday, 18th.	Monday, 19th.	Tuesday, 20th.	Wednesday 21st.	Thursday, 22nd.

A. I. E. E. Director's Meeting

The regular meeting of the Board of Directors of the American Institute of Electrical Engineers was held at Institute headquarters, New York, on Tuesday, February 9, 1926.

There were present: President M. I. Pupin, New York; Past President Farley Osgood, New York; Vice-Presidents Harold B. Smith, Worcester, Mass.; Edward Bennett, Madison, Wis.; L. F. Morehouse, New York; A. G. Pierce, Cleveland, O.; and W. P. Dobson, Toronto, Ont.; Managers H. P. Charlesworth, New York; H. M. Hobart, Schenectady, N. Y.; Earnest Lunn, Chicago, Ill.; G. L. Knight, Brooklyn, N. Y.; W. K. Vanderpoel, New York; John B. Whitehead, Baltimore, Md.; J. M. Bryant, Austin, Tex.; E. B. Merriam, Schenectady, N. Y.; M. M. Fowler, Chicago, Ill.; and H. A. Kidder, New York; National Treasurer George A. Hamilton, Elizabeth, N. J.: National Secretary F. L. Hutchinson, New York.

The minutes of the Directors' meeting held December 11, 1925, were approved as previously circulated.

Reports were presented of meetings of the Board of Examiners held January 11 and 25 and February 5, 1926, and the actions taken at those meetings were approved. Upon the recommendation of the Board of Examiners, the following actions were taken: 268 Students were ordered enrolled; 392 applicants were elected to the grade of Associate; 15 applicants were elected to the grade of Member; 1 applicant was elected to the grade of Fellow; 14 applicants were transferred to the grade of Member; 5 applicants were transferred to the grade of Fellow.

In accordance with a request from Vice-President Morehouse, the Board authorized the holding of a Regional Meeting of Geographical District No. 3, in New York City, in November 1926.

Complying with a request of the Lehigh Valley Section, the Board granted authority for the extension of territory of that Section to include the following additional counties in Pennsylvania: Berks, Wyoming, Wayne, Columbia, Northumberland, and Montour.

A request from the Portland, Seattle, and Spokane Sections for certain readjustments in their boundaries to take in additional territory was referred to the chairmen of the Sections and Finance Committees with power.

Upon the recommendation of the Committee on Student Branches, authority was granted for the organization of a Student Branch of the Institute at Ohio University, Athens, Ohio.

Consideration was given to the report of the Special Committee on Institute Prizes which had been appointed in August 1925 to consider and recommend to the Board of Directors policies and procedure regarding Institute prizes. The recommendations of the committee relating to the establishment and award of National and Regional Prizes were adopted as applicable to all papers presented commencing January 1, 1926. Reference to the policy and procedure regarding Institute prizes thus adopted may be found elsewhere in this issue.

A report was presented from the General Convention Committee of the 41st Annual Convention of the Institute, held at Saratoga Springs, N. Y., June 22-26, 1925, which included a summary of receipts and expenditures in connection with the convention. The report was received with an expression of appreciation and ordered filed for future reference.

With reference to the various actions that have been taken by the Board of Directors defining the Institute's policy regarding standardization matters, and in order to summarize and confirm the general policy of the Institute in such matters, the following resolution was adopted:

Whereas this Board has by various actions taken in recent years adopted a definite policy regarding the relation of the Institute to standardization activities, and

Whereas it appears desirable to restate this policy from time to time, therefore be it

Resolved that the following brief statement of this policy be and hereby is adopted for publication and for transmission to the members of the Standards Committee and to representatives of the Institute upon any other committees, or upon joint bodies, dealing with the formulation of standards:

POLICY OF A. I. E. E. REGARDING THE FORMULATION OF STANDARDS

1. To continue to develop, publish and maintain in the name of the Institute electrical standards as it has done for the past 25 years.
2. That in doing this work the Institute will continue as it has in the past to avail itself to the fullest degree of the assistance of others—both individuals and organizations—with a view to serving the interests of all who may be properly concerned in this work.
3. That standards after having been developed by the Institute in accordance with 1 and 2 and adopted by the Board of Directors as Institute Standards will be, when in the opinion of the Institute such a step is proper, presented to the American Engineering Standards Committee for approval by them as American Standards.
4. That such presentation to the American Engineering Standards Committee for their consideration for approval as American Standard will be done in full conformity with the Constitution, By-Laws and Rules of Procedure of the American Engineering Standards Committee which Committee the Institute was instrumental in initiating and has continued to and does now endorse and support.
5. That when and if standards of the A. I. E. E. have been further advanced to the stage of being designated as "Approved as American Standard by the American Engineering Standards Committee," they shall continue to be printed as standards of the A. I. E. E. with a statement of approval by the American Engineering Standards Committee added to the title page of each particular standard.

The 1925 report of the President of the United States National Committee of the International Commission on Illumination, was presented and received, and copies ordered sent to each member of the Board.

In compliance with a request from the United Engineering Society, the President was authorized to nominate three members of the Institute to serve on a committee of twelve to be appointed by the Trustees of the United Engineering Society to make continuing endeavors to increase the funds of Engineering Foundation and Engineering Societies Library.

An invitation to be represented at the Pan American Congress to be held in Panama, June 18-25, 1926, was referred to the President with power to appoint a delegate.

The President was also authorized to appoint a representative to attend the National Conference on Street and Highway Safety to be held in Washington, March 23-25, in accordance with an invitation from Secretary Hoover of the Department of Commerce.

Other matters of importance were discussed, reference to which may be found in this and future issues of the Journal.

Institute Prizes

At the meeting of the Board of Directors of the Institute held February 9, a report was presented by a special committee appointed several months ago to consider Institute prizes and to make recommendations regarding prizes which should be awarded in the future; also, to formulate the necessary regulations for the award of these prizes. The committee which prepared this report consisted of Messrs. L. W. W. Morrow, Chairman; H. P. Charlesworth; H. A. Kidder; C. E. Magnusson; M. E. Skinner; and A. C. Stevens. The Board adopted the committee's recommendations with an expression of appreciation for the valuable services rendered. The substance of the report is embodied in the following statement relating to the prizes to be awarded for papers presented at National, Regional, Section and Branch meetings during the calendar year 1926 (prizes for 1925 papers will be awarded under the previous rules).

NATIONAL PRIZES

The following National Prizes may be awarded each year.

1. Best Paper Prize.
2. First Paper Prize.
3. Best Regional Paper Prize.
4. Best Branch Paper Prize.

a. The *Best Paper Prize* shall be awarded the author or authors of the best original paper presented at any meeting of the Institute.

b. The *First Paper Prize* shall be awarded the author or authors of the most worthy paper presented at any Institute meeting, provided the author or authors have never previously presented a paper before the Institute.

c. The *Best Regional Paper Prize* shall be awarded the author or authors of the best paper presented at any Regional or Section Meeting of the Institute.

d. The *Best Branch Paper Prize* shall be awarded the enrolled student author or authors of the best paper presented at a Branch meeting.

e. All prizes shall be presented at the Annual Convention of the Institute in June.

f. Prizes will be awarded for papers presented during the calendar year preceding the year during which the Annual Convention is held.

g. A cash prize of $100 and a suitable certificate of award shall be given the author or authors of each paper receiving a prize. At the discretion of the Committee on Award of Institute Prizes, any prize award may be omitted in any year in which at least three papers are not submitted in competition for each prize. Also, at the discretion of this committee, a single paper may be awarded more than one of the prizes available, and honorable mention may be made of papers which did not receive prize awards.

h. All National prizes shall be awarded by the Committee on Award of Institute Prizes. This committee consists of the chairmen of the Meetings and Papers, Publication, and Transmission Committees, and such others as the Board of Directors may designate.

i. To be considered in the competition, all "first" papers and all papers not presented at national conventions, must be presented with a written communication to the National Secretary of the Institute on or before February 15th of the year following the calendar year in which they were presented. Papers presented at any national convention are all eligible for consideration, but "first" papers and those presented at other than national meetings, must be submitted formally. This may be done by the author or authors, by an officer of the Institute, or by the executive committees of the Institute in the Geographical District. As a normal procedure, papers presented for prize awards which were presented at Regional, Section or Branch meetings, shall be presented through the executive committees of the Geographical Districts.

j. Papers, other than those presented at national conventions, must be submitted in triplicate, to the National Secretary of the Institute.

k. Papers awarded prizes shall be published in full or in abstract, in the JOURNAL, in the TRANSACTIONS, or in pamphlet form.

l. All papers submitted for prizes (excepting for the Branch Paper Prize) must be written by members of the Institute, and when papers are written jointly at least one of the authors must be a member of the Institute, and the cash value of the prize shall be divided.

m. The fundamental consideration in the award of the National prizes, is the quality of the contribution made for the advancement of electrical engineering.

REGIONAL PRIZES

The following Regional Prizes may be awarded each year. in each Geographical District of the Institute.

1. Best Paper Prize.
2. First Paper Prize.
3. Best Branch Paper Prize.

a. The *Best Paper Prize* shall be awarded the author or authors of the best paper presented at Regional, Section or Branch Institute meeting in the District.

b. The *First Paper Prize* shall be awarded the author or authors of the best paper presented at an Institute meeting in the District, provided the author or authors have never before presented a paper before the Institute at any National, Regional or Section meeting.

c. The *Best Branch Paper Prize* shall be awarded the author or authors of the best paper presented at a Branch or Regional meeting of the Institute in the District. The authors must be enrolled Students of the Institute.

d. *Regional Prize Awards* shall be made by the District executive committees or by another committee appointed by the District executive committee.

e. Each prize shall consist of $25 from the national treasury, and a suitable certificate of award issued by the officers of the Geographical District concerned.

f. Papers must be submitted in duplicate to the District Committee on Awards, on or before January 10th of the year following the calendar year in which the papers have been presented.

g. All Regional papers submitted in competition for National prizes, which have been presented at other than national meetings, should be submitted to the National Secretary of the Institute through the District executive committee or by the authorized District Committee on Prize Awards. If in any District this procedure is inadvisable, papers may be submitted directly to the National Secretary by an officer of the Institute in the District.

Scientific Congress

BRUSSELS, BELGIUM—JUNE 1926

During June next, the Association of Engineers of Brussels will celebrate the fiftieth anniversary of its foundation.

A scientific congress will be held upon this occasion, comprising two sections, one on civil engineering and the other on mechanics, electricity, chemistry and various industries.

The Institute has been invited to be represented at this congress, and American members who contemplate being in Belgium in June are requested to advise the National Secretary promptly, at Institute Headquarters, New York, so that any additional information which may be received, including the exact dates of the congress may be sent to them.

John Fritz Medal Award

The date for the presentation of the John Fritz Medal to Edward Dean Adams has been fixed for the evening of Tuesday, March 30th, at 8:15 p. m. in the Engineering Auditorium. The Board of Award, representing the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers, the American Society of Mechanical Engineers and the American Institute of Electrical Engineers, extends a cordial invitation to all interested friends. The award will be made by Fred J. Miller, Chairman of the Board, and the speakers of the evening will be the Honorable James Montgomery Beck, formerly Solicitor-General of the United States and Arthur Edwin Kennelly, D. Sc., Professor of Electrical Engineering, Harvard University and Massachusetts Institute of Teohnology.

Electrical Heating Conference at Purdue

Electric heat treating of metals in industry, including the use of electric furnaces and similar equipment, will be the subject for a state-wide conference of manufacturers and electric power producers to be held at Purdue University, Lafayette, Ind.,

March 16, 17 and 18. The conference which will be largely in the nature of a school with demonstrations of every description, relating to the use of electric heat treating equipment, was decided on at a recent meeting of Prof. C. F. Harding of the School of Electrical Engineering, and Prof. W. A. Knapp, in charge of the engineering extension department, with state utility men.

Among the features already arranged included a visit to the Ross Gear and Tool Works at Lafayette which has in operation two electric furnaces and plans to install more during the coming months.

Nomination of Officers of New York Section for Year 1926-27

On February 15, 1926 The Executive Committee of the New York Section of the A. I. E. E. appointed a Nominating Committee as follows: L. F. Morehouse, Chairman; H. H. Barnes, C. E. Stephens, J. C. Parker, E. E. Dorting. The committee is particularly desirous of receiving suggestions from members of the Section for officers for 1926-27. A Chairman, secretary-treasurer, and two members of the Executive Committee are to be nominated. Petitions signed by not less than ten members of the Section may be made and should be received prior to March 8, 1926. Send your suggestions or petitions to L. F. Morehouse, Chairman Nominating Committee New York Section, 33 West 39th St., New York, N. Y.

Columbia University Offers Scholarship in Electrical Engineering

The governing bodies of Columbia University have placed at the disposal of the American Institute of Electrical Engineers each year a scholarship in Electrical Engineering in the Schools of Mines, Engineering and Chemistry of Columbia University. The scholarship pays $350 toward the annual tuition fees which vary from $340 to $360, according to the details of the course selected. Reappointment of the student to the scholarship for the completion of his course is conditioned upon the maintenance of a good standing in his work.

To be eligible for the scholarship, the candidate recommended will have to meet the regular admission requirements, in regard to which full information will be sent without charge upon application to the Secretary of the University or to the National Secretary of the Institute.

In a letter addressed to the National Secretary of the Institute, an applicant for this scholarship should set forth his qualifications (age, place of birth, education, reference to any other activities, such as athletics or working way through college, references and photograph). A committee composed of Messrs. W. I. Slichter, Francis Blossom and H. C. Carpenter will consider the applications and will notify the authorities of Columbia University of their selection of a candidate The last day for filing of applications for the year 1926-27 will be June 1, 1926.

The course at the Columbia School of Mines, Engineering and Chemistry, is three years in length and is on a graduate basis. A candidate for admission must have had something of a general education, including considerable work in mathematics, physics and chemistry. Three years of preparatory work in a good college or scientific school should be sufficient, if special attention has been given to the three preparatory subjects mentioned. A college graduate, with a Bachelor of Science degree in engineering can generally qualify to advantage. The candidate is admitted on the basis of his previous collegiate record, and without undergoing special examinations.

The purpose of this advanced course is to produce a high type of engineer, trained in the humanities as well as in the fundamentals of his profession. It is hoped that enrolled students and others qualified will show a keen interest in this scholarship.

Electrical Exhibition Held By Yale Branch

On December 11-12, 1925, an electrical exhibition at which many interesting displays were made, was held by the Yale University Branch of the Institute in the Dunham Laboratory, and attended by two thousand people.

Among the exhibits were a miniature power plant, a miniature electric train and railway substation, motors and control, high-voltage equipment, household refrigerators and other appliances, an automatic telephone exchange, radio and telegraph demonstrations, and numerous interesting trick displays.

University of Illinois Offers Research Assistantships

To assist in the conduct of engineering research and to extend and strengthen the field of its graduate work in engineering, the University of Illinois maintains fourteen Research Graduate Assistantships in the Engineering Experiment Station. Two other such assistantships have been established under the patronage of the Illinois Gas Association. These assistantships, for each of which there is an annual stipend of $600 and freedom from all fees except the matriculation and diploma fees, are open to graduates of approved American and foreign universities and technical schools who are prepared to undertake graduate study in engineering, physics, or applied chemistry.

An appointment to the position of Research Graduate Assistant is made and must be accepted for two consecutive collegiate years of ten months each, at the expiration of which period, if all requirements have been met, the degree of Master of Science will be conferred. Half of the time of a Research Graduate Assistant (approximately 900 clock hours for each ten-month period) is required in connection with the work of the department to which he is assigned, the remainder being available for graduate study.

Nominations to these positions, accompanied by assignments to special departments of the Engineering Experiment Station, are made from applications received by the Director of the Station each year not later than the first day of April. The nominations are made by the Executive Staff of the Station, subject to the approval of the President of the University. Nominations are based upon the character, scholastic attainments, and promise of success in the principal line of study or research to which the candidate proposes to devote himself. Preference is given those applicants who have had some practical engineering experience following the completion of their undergraduate work. Appointments are made in the spring, and they become effective the first day of the following September. Vacancies may be filled by similar nominations and appointments at other times.

Research work and graduate study may be undertaken in architecture, architectural engineering, ceramic engineering, chemistry, civil engineering, electrical engineering, mechanical engineering, mining engineering, municipal and sanitary engineering, physics, railway engineering, and theoretical and applied mechanics.

Additional information may be obtained by addressing The Director, Engineering Experiment Station, University of Illinois, Urbana, Illinois.

Research Fellowships in Lehigh University

On or before June 1, 1926, the Institute of Research of Lehigh University will appoint three research fellows, as follows:

1. One New Jersey Zinc Company Research Fellow in Science and Technology, with endowment provided by the New Jersey Zinc Company. Appointment to this Fellowship will be for the period of two academic years beginning September 1, 1926, annual stipend $600, payable in ten monthly installments, and freedom from University fees, except the matriculation fee of $5.00 and the graduation fee of $10.00. Half of the time of the holder must be devoted to research work in the field

of science or technology to which he is assigned; the other half to graduate study leading to the degree of Master of Science at the end of the two year appointment, providing all University requirements for this degree have been satisfied.

2. TWO HENRY MARISON BYLLESBY MEMORIAL RESEARCH FELLOWS IN ENGINEERING, with endowment provided by widow of Col. Henry M. Byllesby, (M. E., Lehigh, 1875), President of the Byllesby Engineering and Management Corporation. Appointment to either of these Fellowships will be for the period of two academic years, beginning September 1, 1926, with an annual stipend of $750, payable in ten monthly installments, and freedom from University fees, except the matriculation fee of $5.00 and the graduation fee of $10.00. Half of the time of the holders must be devoted to research work on some problem in electrical, mechanical or hydraulic engineering proposed by the President of the Byllesby Engineering and Management Corporation and approved by the Institute of Research; the other half to graduate study leading to the degree of Master of Science at the end of the two year appointment, providing that all University requirements for this degree have been satisfied.

Applications for appointment may be submitted by graduates in engineering or science of colleges, universities or technical schools whose requirements for graduation are substantially the equivalent of those at Lehigh University. Applications must be submitted before May 1, 1926, and they must be accompanied by a catalog of the institution from which the applicant graduated, a certificate of his college work, a list of three or more references, a recent photograph of himself, together with a statement concerning his practical experience and any other evidence of his qualifications for the position which he may choose to submit. The applicant must also indicate the line of graduate study he desires to undertake and his special qualifications for such work.

As previously indicated, appointment to these Fellowships is for the period of two years of ten months each. The holder of each of these Fellowships is required to devote approximately ninety hours per month to research work, under the direction of the Head of the department to which he is attached, without allowances for holidays or vacations during the academic year. Each appointee must pledge himself to remain through the full term of his appointment and to refrain from accepting any kind of employment during either ten month period included therein.

Applications or requests for additional information should be addressed to: CHARLES RUSS RICHARDS, President, Lehigh University, Bethlehem, Pa.

National Museum of Engineering and Industry

In accordance with an invitation extended by the National Museum of Engineering and Industry to several Societies many of whose members had joined it individually to nominate representatives to its Board of Trustees, the National Societies of Civil, Mining, Mechanical and Electrical Engineers, the American Association for the Advancement of Science, the American Chemical Society and the Society for the Promotion of Engineering Education have responded favorably and are now represented on its Board constituted as follows:

SAMUEL INSULL
CHAIRMAN

L. P. ALFORD[3]	FREDERICK A. HALSEY
B. C. BATCHELLER	DUGALD C. JACKSON[7]
NICHOLAS F. BRADY	LUIS JACKSON
F. H. COLVIN	F. B. JEWETT[4]
NORMAN DODGE	JOHN W. LIEB
GANO DUNN[4]	FRED R. LOW[3]
A. S. DWIGHT[2]	W. W. MACON
THOMAS EWING	L. C. MARBURG
JOHN R. FREEMAN[1]	H. P. MERRIAM
MICHAEL FRIEDSAM	M. I. PUPIN[5]
H. A. GILLIS	W. L. SAUNDERS[2]
HENRY GOLDMARK	J. WALDO SMITH[1]

ELMER A. SPERRY[6]

1 Nominated by American Society of Civil Engineers.
2 " American Institute of Mining and Metallurgical Engineers
3 " American Society of Mechanical Engineers.
4 " American Institute of Electrical Engineers.
5 " American Association for the Advancement of Science.
6 " American Chemical Society.
7 " Society for the Promotion of Engineering Education.

Many of its members have donated original historical documents, old patent records, books, drawings, prints, models, photographs and descriptions of important work, etc., to the National Museum and correspondence regarding these things is solicited.

The Secretary would like to hear by letter from any one recounting items of historical value or interest or, if they should happen to be in the neighborhood, he would welcome a call during which experiences may be dictated to his amanuensis. all of these accounts will be carefully catalogued and placed in the research file for the reference of any one who can make proper use of them. They will eventually go for permanent preservation to the National Museum which is to be part of the Smithsonian Institution at Washington.

The Secretary may be addressed as follows: H. F. J. Porter, Secretary, National Museum of Engineering and Industry, 29 West 39th Street, New York City.

Ocean Magnetic and Electric Observation Carnegie Institution

A fifth volume of "Researches of the Department of Terrestrial Magnetism" has appeared from the press of the Carnegie Institution, Washington, D. C. This volume contains articles on Magnetic Results by J. P. Ault, Atmospheric-Electric Results by Messrs. J. P. Ault and S. J. Mauchly, and also further data on Ocean magnetic and electric observation and studies in atmospheric electricity based on observations made aboard the *Carnegie* during its cruises during the years 1915-21.

Midwest Power Conference Held in Chicago

To consider how the available power resources of the country, especially of the middlewest section, might best be developed for the benefit of the people and the industries, a meeting known as the Midwest Power Conference was held in Chicago in the Furniture Club of America, January 26 to 29. This conference was sponsored by the local divisions of the A. I. E. E., A. S. M. E., A. I. M. E., N. E. L. A., Western Society of Engineers and the National Safety Council.

The conference opened with an address by Samuel Insull on "Power Developments in the Mississippi Valley," followed by the presentation of seventeen papers dealing with the advantages of full development, distribution and use of power resources, fuel, boilers, turbines, diesel engines, power generation, industrial power, superpower, rural service and safety first aid. G. E. Pfisterer, 37 W. Van Buren St., Chicago, was Secretary of the General Arrangement Committee.

Library Service

As few members of the American Institute of Electrical Engineers appreciate the very convenient and practicable service offered by the Engineering Societies Library and as I have personally found it most useful, I should like to point out to readers of the JOURNAL some of the opportunities it offers through its expert staff.

The library will furnish, at short notice, photoprint copies of pages of any available book or periodical, including illustrations, at 25 cents a page. This will permit, for example, obtaining a permanent copy of any article or extract, for which only a reference is available.

In case of long articles which would be expensive to photoprint, complete, the library will sometimes make the prints and

loan them at a reasonable per diem charge with the option of subsequent purchase.

The library will translate any available article in a foreign language at about $6.00 a thousand words, so that references to foreign articles can be very readily investigated.

The library will make searches of the periodicals or technical books and list all articles bearing on any particular subject matter that may be prescribed. Where such a search is to be for general information, or to find what has been written about some particular matter or what has been done to solve a special problem, the time required is short and the charge small. In the case of patent searches or exhaustive studies, the time and charges will be such as may be appropriate.

This is an extremely convenient and valuable service when one gets in the habit of using it, especially for an engineer who has new designs to make or new problems arising from time to time.

The library will lend books where duplicates are available for a 5 cents per diem charge, delivering them by mail, and such books are available on many subjects. They may usually be subsequently purchased.

The library has a sort of clipping bureau to the extent that it will follow the technical periodical press and regularly send notices or articles or books appearing on any particular subject, an appropriate charge being made.

In general the library is ready in any practicable manner to use the books and periodicals and the services of the staff to help members of the founder societies or any other persons who may wish to take advantage of the facilities, to get any information that may be wanted, quickly, and conveniently, and without visiting the library, if desired. Engineers should make use of this service as often as possible, first because as they come to realize the convenience of it they will obtain great benefit and second because it strengthens the library and enables better service to be given.

PERCY H. THOMAS

ENGINEERING FOUNDATION

ELECTION OF OFFICERS

At the annual meeting of Engineering Foundation February 11, the following officers were elected for the ensuing year: Chairman, Lewis B. Stillwell (member, American Institute of Electrical Engineers, American Society of Civil Engineers); Vice-Chairman, Elmer A. Sperry (member, American Institute of Electrical Engineers, American Society of Mechanical Engineers). George A. Orrok (member, American Society of Mechanical Engineers, Am. Inst. of Mining and Metallurgical Engineers, American Society of Civil Engineers). Additional members of Executive Committee, J. Vipond Davies, (member Am. Inst. of Mining & Metallurgical Engineers, Am. Society of Civil Engineers). Arthur M. Greene, Jr., (member, American Society of Mechanical Engineers). Director and Secretary, Alfred D. Flinn; Treasurer, Jacob S. Langthorn; Assistant Treasurer, Henry A. Lardner.

United Engineering Society

EXTRACTS FROM PRESIDENT'S REPORT FOR YEAR 1925

Throughout 1925, as in the preceding year, the energies of the Trustees were devoted largely to improving the investment of trust funds. Especial attention was given to the Engineering Foundation endowment. A new active bank account was authorized to be established January 1, 1926 at the Fifth Avenue branch of The Farmers' Loan and Trust Company.

In June, the $50,000 legacy establishing the Henry R. Towne Engineering Fund was received in cash. It has been invested.

Assessment of Engineering Societies Building for taxation in 1925 was reduced by the Department of Taxes and Assessments, after a hearing, from $1,450,000 to $195,000, applying only to space occupied by taxable organizations.

A medallion of General Pershing was placed in the Entrance Hall as a companion to the medallion of Marshal Foch received in 1921. In December, the flags of the 24th Regiment of Engineers (Mechanical) were received and placed in the cabinet with the flags of the 27th Engineers received in 1924.

President Ralph Budd, of the Great Northern Railway, presented to United Engineering Society a bronze replica of the statue of John F. Stevens, Hon. M. Am. Soc. C. E., set up last July in Marias Pass through the Rocky Mountains, which he discovered. The statuette was placed in the Library.

A name for the Auditorium in Engineering Societies Building was adopted in December. It is "Engineering Auditorium."

By direction of the Board of Trustees, the Secretary has prepared a History of United Engineering Society and the Fifth Revision of the Charter and By-Laws.

Engineering Societies Building is in excellent condition and fully occupied, with a waiting list. Erection of new buildings and remodeling of old ones in the vicinity have improved the external fire hazard. In November, a contract was made with the New York Steam Corporation for heating service from its new main in 39th Street and at the end of the year the necessary piping was being installed.

Memberships of the Founder Societies at the end of 1925 totaled 55,695 and of the Associate Societies 52,204, an aggregate of 107,899 engineers having headquarters in our building.

All departments of United Engineering Society closed the year without deficits. The assets for which the Society is responsible (real estate at cost, trust funds at book value, and Library as appraised) total $3,145,395.44.

BALANCE SHEET

ASSETS

Real Estate:		
Land	$ 540,000.00	
Building	1,369,398.28

MEETING OF THE BOARD OF TRUSTEES

At the annual meeting of the Board of Trustees of United Engineering Society held January 28, the following officers were elected for the ensuing year: President, W. L. Saunders; 1st Vice-President, Bancroft Gherardi; 2nd Vice-President, Lewis D. Rights; Secretary, Alfred D. Flinn; Treasurer, Jacob S. Langthorn and Assistant Treasurer Henry A. Lardner.

PERSONAL MENTION

H. W. YOUNG, President of the Delta-Star Electric Co., Chicago, sailed March 6th on the Berengaria for a six weeks business trip to England, France and Italy. He is accompanied by Mrs. Young.

B. LAZICH has resigned his position in the Equipment Engineering Department of the Bell Telephone Company at Pittsburgh, to accept a position in the engineering department of the Union Switch and Signal Co. at Swissvale. Pa.

HAZAEL COLATINE PRADO, of Santander, Cauca. Columbia, S. A., an Associate of the Institute. has been laying out a new town of over 62 plazas, at the hacienda of La Libertad, Municiple de San Joaquin, Caldas. These blocks consist of sixteen lots 15 x 30 meters, given away by the owner.

WALTER P. HOLCOMBE, member of the Institute and JOHN C. PARKER, Fellow, were appointed vice-presidents of the Brooklyn Edison Company at a meeting of the board of directors yesterday. Mr. Holcombe has been purchasing agent for the company for several years, and Mr. Parker has been chief electrical engineer for the Company.

A. W. BERRESFORD, Fellow of the Institute and its President during the year 1920-21, has just been appointed executive vice-president of the Nizer Corporation, Detroit, manufacturers of the Nizer Electric Ice Cream cabinets and automatic refrigerating units. Mr. Berresford, for some twenty years, has been vice-president and general manager of the Cutler-Hammer Manufacturing Company. He was also recently elected vice-president of the American Engineering Council.

MISS EDITH CLARKE, Associate of the Institute and for the past six years, engineer of the General Electric Company at Schenectady, N. Y., is the first woman member to present a paper before the American Institute of Electrical Engineers, when her paper, *Steady-State Stability in Transmission Lines*, was delivered at the Midwinter Convention of last month. Miss Clarke is a Vassar graduate, she took her engineering degree at Massachusetts Institute of Technology and upon April 13, 1923, became one of five women members of the A. I. E. E.

FARLEY OSGOOD, Past-President of the Institute, has opened offices in the National Bank of Commerce Building, New York, for consulting engineering in the design, construction, operation and interconnection of public utilities.

After receiving his education at Massachusetts Institute of Technology, Dr. Osgood went in 1894 with the American Bell Telephone Company, Boston. In 1897-98, he affiliated himself with the New England Telephone and Telegraph Company, and finally became Division Manager of the New York and New Jersey Telephone Company. In 1904 he was appointed Chief Engineer and General Manager of the New Milford Power Company, and in 1908 he was made General Superintendent of the Public Service Electric Company of New Jersey, advancing later to the position of Vice-President and General Manager of that Company.

He has always been an active worker in the A. I. E. E., the N. E. L. A. and other representative organizations. In 1911-14, he was a Director of the Institute, Vice-President in 1914-15-16 and President in 1924-25. From 1921 to 1922 he was Chairman of the Institute's New York Section, and he has served the Institute also on the following committees: Executive, Finance, Edison Medal, Standards, Safety Codes and others.

L. C. BROOKS, who has been identified with marine electrical applications since the inception of the art on the *U. S. S. Kearsarge* and *Kentucky*, twenty-five years ago, and for the last eight years electrical engineer of the Bethlehem Shipbuilding Corporation, has resigned. Mr. Brooks has been chairman of the A. I. E. E. Committee on Applications to Marine Work for two years. He expects to take a much needed vacation, after which his plans may lead him into an entirely new field of activity.

Obituary

Edmund Hugh Pryce died at his home, 568 West 149th Street, New York City, on February 12th. Born at Llanidloes, Wales, in 1872, Mr. Pryce's early education was through the English Grammar School at the Oswestry Grammar School, South Kensington course at Oswestry. For five years he was apprenticed in technical shops and offices of the Cambrian Railway Company. This was followed by two years' training in mechanical and electrical engineering with the Central Marine Engine Company. He was also with the British India Steam Navigation Company for seven years in varying capacities and held the Chief Engineers Certificate granted by the Board of Examiners, Trinity House, London. Coming to the United States, Mr. Pryce was first engaged with the National Automatic Fire Alarm Company as constructing Electrical Engineer, but left them very shortly to enter the Wool Exchange. Mr. Pryce joined the Institute in 1904 but continued as an Associate until the time of his death.

Charles C. Clancy Grandy, Radiologist of the Lutheran Hospital, Fort Wayne, Indiana, an Associate of the Institute since 1920, and past-chairman of the Fort Wayne Section of the A. I. E. E., (1923-1924) died the morning of February 12th, 1926. Doctor Grandy was born at Wall Lake, Iowa. After finishing High School at Warsaw, Indiana, he entered the Indiana University from which he obtained his A. B. in 1908 and A. M. in 1909. He next attended the Rush Medical College, Chicago, Illinois, from which he graduated with his M. D. degree in 1911. Since then he has been doing the X-ray work at the Fort Wayne Lutheran Hospital, having charge of the laboratory there. Doctor Grandy will be much missed by his medical colleagues as well as by the members of the Institute's Fort Wayne Section. Due to his death, the meeting scheduled for February 12th was cancelled.

Robert Alexander Paine, Jr., after an illness of a month's period, died at the Methodist Episcopal Hospital, Brooklyn, February 7th. His death is keenly felt by his business associates in the Brooklyn Edison Company, for whom he has been plant engineer for some time past. He was born in Richmond, Va., August 30, 1887 and his early schooling was obtained in the Ashland Grammar School, Ashland, Va. September 1904 he entered the Randolph-Macon College, at Ashland, obtaining his A. B. degree there in 1905. He next attended the Virginia Polytechnic Institute, Blacksburg, Va., whence he graduated June 1908 with a B. S. degree in Electrical Engineering and in June 1909 with a degree in Mechanical Engineering. June 1910 he entered the Testing Department of the General Electric Company, Schenectady, but left the following year to become assistant to the Chief Engineer of the Coney Island and Brooklyn Railroad Company, Brooklyn, N. Y. Here he was promptly appointed acting electrical engineer in charge of electric operation, remaining with them until in 1914 he became general foreman, Development Research Bureau of the Edison Electric Illuminating Company of Brooklyn. Mr. Paine was elected to the grade of Associate in the Institute in 1913.

Addresses Wanted

A list of names of members whose mail has been returned by the Postal Authorities is given below, together with the addresses as they now appear on the Institute records. Any member knowing the present address of any of these members is requested to communicate with the Secretary at 33 West 39th St., New York, N. Y.

All members are urged to notify the Institute Headquarters promptly of any change in mailing or business address, thus

relieving the member of needless annoyance and also assuring the prompt delivery of Institute mail, the accuracy of our mailing records, and the elimination of unnecessary expense for postage and clerical work.

1.—William E. Ames, Detroit Edison Co., Research Div., Detroit, Mich.
2.—H. R. Bailey, Room 923, Electric Bldg., Portland, Ore.
3.—J. E. Contesti, 350 W. 58th St., New York, N. Y.
4.—Ralph Elsman, 120 Broadway, New York, N. Y.
5.—L. W. Ferguson, Box 331, Barbourville, Ky.
6.—Chas. A. Foust, 10505 93rd St., Woodhaven, N. Y.
7.—George Frasher, 1209 So. 4th Ave., Louisville Ky.
8.—S. Alden Griffin, 19 Elliott St., Springfield, Mass.
9.—Harold G. Haines, 7416 Sylvester, Detroit, Mich.
10.—Wm. J. Hay, 320 Second St., Aspinwall, Pa.
11.—Wendell E. Haywood, 823 Boatmens Bank, St. Louis, Mo.
12.—Elmer D. Johnson, 1481 Harvard St., Washington, D. C.
13.—Harry W. Kohler, 200 14th St., Milwaukee, Wis.
14.—Charles L. Leaf, 175 Dodd St., East Orange, N. J.
15.—John E. Lewis, 376 Meyran Ave., Oakland Station, Pittsburgh, Pa.
16.—Chas. W. Magee, c/o Pelser, 210 West 102nd St., New York, N. Y.
17.—J. A. McDermott, Y. M. C. A. Lima, Ohio.
18.—Raymond W. Noddins, 230 East Ohio St., Chicago, Ill.
19.—Lieut. A. G. Scott, 68 West 107th St., Apt. 2D, New York, N. Y.
20.—A. B. Smedley, c/o Cooper Hewitt Elec. Co., 1406 First Nat'l Bank, Cincinnati, Ohio.
21.—C. D. Smith, 857 St. Charles St., New Orleans, La.
22.—Will M. Strickler, 301 Detroit Life Bldg., Detroit, Mich.
23.—A. R. Williamson, 561 Delaware Ave., Norwood, Pa.

Book Review

ANNUAL PROCEEDINGS OF THE A. S. T. M. Prices: $6.00 in paper, $6.50 in cloth and $8.00 in half-leather binding.

Part I (962 pp.) contains the annual reports of 35 of the standing committees of the Society, with the discussion thereon at the annual meeting. These include reports of Committees on Ferrous Metals, Non-Ferrous Metals, Cement, Ceramics, Concrete Gypsum, Lime, Preservative Coatings, Petroleum Products, Road Materials, Coal and Coke, Water-proofing Materials, Electrical Insulating Materials, Rubber Products, Textile Materials, Thermometers, Metallography, including a report on Metal Radiography and X-ray Crystallography. Methods of Testing and Nomenclature and Definitions: 83 tentative standards which have either been revised or are published for the first time; annual address of the President and the annual Report of the Executive Committee.

Part II (454 pp.) contains 26 technical papers with discussion, giving valuable information regarding results of investigations by experts in the field of engineering materials including the fatigue of metals, the effect of temperature on the properties of metals and investigations on the corrosion of metals. Mention should also be made of the many papers on cement and concrete and on the stability of bituminous mixtures as well as on such subjects as bituminous materials, paint, gypsum, brick, textiles, etc.

Engineering Societies Library

The library is a cooperative activity of the American Institute of Electrical Engineers, the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers and the American Society of Mechanical Engineers. It is administered for these Founder Societies by the United Engineering Society, as a public reference library of engineering and the allied sciences. It contains 150,000 volumes and pamphlets and receives currently most of the important periodicals in its field. It is housed in the Engineering Societies Building, 29 West Thirty-ninth St., New York.

In order to place the resources of the Library at the disposal of those unable to visit it in person, the Library is prepared to furnish lists of references to engineering subjects, copies or translations of articles, and similar assistance. Charges sufficient to cover the cost of this work are made.

The Library maintains a collection of modern technical books which may be rented by members residing in North America. A rental of five cents a day, plus transportation, is charged.

The Director of the Library will gladly give information concerning charges for the various kinds of service to those interested. In asking for information, letters should be made as definite as possible, so that the investigator may understand clearly what is desired.

The library is open from 9 a. m. to 10 p. m. on all week days except holidays throughout the year except during July and August when the hours are 9 a. m. to 5 p. m.

BOOK NOTICES (JAN. 1-31 1926)

Unless otherwise specified, books in this list have been presented by the publishers. The Society does not assume responsibility for any statement made; these are taken from the preface or the text of the book.

All books listed may be consulted in the Engineering Societies Library.

ADMINISTRATION OF INDUSTRIAL ENTERPRISES.

By Edward D. Jones. New edition. N. Y., Longmans, Green & Co., 1925. 618 pp., illus., tables, 9 x 6 in., cloth. $4.75.

The purpose of this book is to present in compact outline a survey of the art of business management as it exists in the United States at this time. The treatment aims to present practise with reasonable fullness of detail but, wherever possible, to deduce and formulate the general principles, or the philosophy, controlling action.

The chief outstanding characteristic is the inclusion, for the first time in such a treatise, of a full discussion of the underlying general principles of administration which govern all efficient joint enterprises, whether of a business nature or otherwise.

This edition has been thoroughly revised, the new material exceeding the subject matter of the first edition. The numerous bibliographies have been brought up to date.

AERONAUTICAL METEOROLOGY.

By Willis Ray Gregg. N. Y., Ronald Press Co., 1925. (Ronald Aeronautic Library). 144 pp., illus., diagrs., tables, 9 x 6 in., cloth. $2.50.

Intended to give concisely the essential facts concerning the upper air and to point out their relation to the development and safety of aeronautics. The book is intended for pilots, aeronautical engineers and others requiring an intimate knowledge of the characteristics of the atmosphere.

ARCHITECTURAL IRON DESIGN AND DETAILING, as Required by the Laws of New York.

By Daniel M. Driscoll. N. Y., D. Van Nostrand Co., 1926. 349 pp., illus., plates, tables, 8 x 11 in., cloth. $4.00.

The subjects covered are the designing and detailing of stairs, elevator drip pans, door bucks, door saddles, doors, gratings, sidewalk gratings and other miscellaneous metal work, and fire-escapes; and the fabricating and setting of light structural steel. Appendices give useful tables, cuts of stock ornamental moulding and shapes, the Building Code of New York City, the Tenement House Law and Labor Law of New York State, the Code of Ordinances and the Rules of the Board of Standards and Appeals of New York City, and a glossary. The book is intended for draftsmen, not beginners. It should be particularly useful be-

cause of its careful attention to the laws governing the design of these articles.

BUREAU OF STANDARDS.

By Gustavus A. Weber. Balt., Johns Hopkins Press, 1925. (Institute for Government Research. Service monographs, no. 35). 299 pp., illus., 9 x 6 in., cloth. $2.00.

The history, activities and organization of the Bureau of Standards are presented in detail in this volume, which gives a complete account of its purpose, its achievements and their cost. The laws governing it, the character of its plant, its functions and its personnel are described, and a full bibliography of the sources of information bearing on it is given.

CONDENSED COLLECTION OF THERMODYNAMIC FORMULAS.

By P. W. Bridgman. Cambridge, Harvard University Press, 1925. 34 pp., 9 x 6 in., cloth. Price not quoted.

This collection of formulas is intended both for students of thermodynamics and for use in practice. The formulas given apply to systems for which temperature and pressure are a possible set of independent variables; and to systems for which pressure is a function of temperature, and temperature and volume are a possible set of independent variables. The latter table applies to two-phase systems such as water and steam in contact.

Illustrative examples show how the tables are used. The author also shows how to extend the tables, in a number of cases, to systems subjected to other external forces than a hydrostatic pressure.

THE DYNAMO....v. 3, Alternators.

By C. C. Hawkins. 6th edition. N. Y., Isaac Pitman & Sons, 1925. 572 pp., illus., diagrs., 9 x 6 in., cloth. $8.50.

The first two volumes of this edition appeared a few years ago. They are now supplemented by a third volume devoted to alternators. It discusses armature winding, the loop e.m. f. of the heteropolar and the toothed armature, armature reactions, the construction of armatures and field magnets, the design of the salient-pole alternator, the turbo-alternator with cylindrical rotor and the parallel working of alternators. The treatment is brief enough for the student, but is intended to provide a basis for further consideration of the various phenomena discussd, with reference to sources of more detailed information.

ELECTRICAL POWER AND NATIONAL PROGRESS.

By Hugh Quigley. Lond., George Allen & Unwin, 1925. 160 pp., graphs, 9 x 6 in., cloth. 8-6.

The volume, which is based on articles that have appeared in various British newspapers, examines the probable effects of a reorganization of power generation and distribution on the industrial life of Great Britain, and the economic consequences of the national development of electrical power.

HISTORY OF ENGINEERING.

By A. P. M. Fleming & H. J. Brocklehurst. Lond., A. & C. Black; [N. Y., Macmillan Co.], 1925. 312 pp., illus., 9x6 in., cloth. 12/6.

The title is misleading, for with the exception of a chapter on ancient engineering, the account is limited to the development of engineering in Great Britain. For that country, the authors give a concise, readable account of progress in the refinement of measurement; the construction of docks, harbors, canals, roads and bridges; the invention of the steam engine; the development of railroad, gas, oil and electric engineering; and of the influence of progress in iron making on engineering.

HUTTE, DES INGENIEURS TASCHENBUCH, v. 1.

By Akademischen Verein Hütte. Berlin, Wilhelm Ernst & Sohn, 1925. 1080 pp., diagrs., table. 8 x 5 in., cloth. 12,20 mk.

When twenty-five editions of a book have been called for in sixty-eight years, its popularity is evident. In spite of its frequent revision, the new edition shows still further important changes and novelties. An attempt has been made to collect the theoretical principles of all engineering in volume one, and this has necessitated some rearrangement. A new section, "Technical physics," has been added, and new chapters provided on nomography and the kinetics of gearing. All sections have been carefully revised and new standards have been adopted.

INDUCTION MOTOR IN THEORY, DESIGN AND PRACTICE.

By Herbert Vickers. N. Y., Isaac Pitman & Sons, 1925. 322 pp., diagrs., plates, tables, 9 x 6 in., cloth. $6.00.

Primarily intended to introduce the student electrical engineer to the theory and design of these motors, this is a well-balanced text-book, in which an endeavor is made to place design on a firm scientific basis. The latest developments in speed control and power-factor control are dealt with.

THE INDUSTRIAL MUSEUM.

By Charles R. Richards. N. Y., Macmillan C., 1925. 117 pp., illus., 10 x 6 in., cloth. $3.00.

During the year 1923-24, the author made a survey of foreign museums of industrial art for the American Association of Museums. The present book forms part of the report submitted and deals with industrial museums.

The museums described include the Conservatoire des Arts et Métiers, the Science Museum, the Deutsches Museum, and the Technisches Museum für Industrie und Gewerbe in Wien. There are also a chapter on industrial museums in this country and appendices on various foreign museums devoted to particular subjects, such as traffic, the marine and agriculture. The illustrations include photographs of many of the more interesting exhibits.

LOCKWOOD'S DIRECTORY OF THE PAPER AND ALLIED TRADES. 1926.

N. Y., Lockwood Trade Journal Co., 1925. 942 pp., 9 x 6 in., cloth. $7.50.

This directory lists the paper mills of North and South America, showing their locations, officers, equipment and capacity. It also contains a directory of mill officials and classified lists of the mills making different papers, of makers of paper specialties, of paper merchants, of dealers in raw materials, of paper box manufacturers, of stationers of brands and of trade associations. The book covers every brand of the industry and has long been the authority in its field.

MERCURY-ARC RECTIFIERS AND MERCURY-VAPOUR LAMPS.

By J. A. Fleming. Lond. & N. Y., Isaac Pitman & Sons, 1925. 100 pp., illus., diagrs., 7 x 5 in., cloth. $1.75.

Now that this rectifier has become available for electrical work on a large scale and has reached a durability and efficiency comparable with that of dynamos, its working and use are of interest to all electrical engineers. The mercury-vapor lamp has also important commercial and therapeutic uses. The present little book has been written to supply a small treatise on the mode of operation and the uses of these devices.

STATEMENT AND ENGINEERING REPORT SUBMITTED TO THE INTERNATIONAL JOINT COMMISSION RESPECTING THE PROPOSAL TO DEVELOP THE ST. LAWRENCE RIVER. 1921.

By Hydro-Electric Power Commission of Ontario. Toronto, 1925. 119 pp., plans, maps, tables, 10 x 7 in., cloth. $7.50.

When the International Joint Commission was empowered, in 1920, by the governments of Canada and the United States to make a special investigation respecting the improvement of the St. Lawrence River, the Hydro-Electric Power Commission of Ontario arranged that the information which it already possessed should be supplemented with the information obtained by additional research and the whole reduced to a report intended to help the International Joint Commission in its investigation.

This was done, but as the report has never appeared in print, the Hydro-Electric Power Commission has now published it. The report is directed to plans for power development, but the improvements are planned, it is stated, to safeguard navigation.

TALKS ABOUT RADIO....

By Sir Oliver Lodge. N. Y., George H. Doran Co., 1925. 267 pp., 8 x 6 in., cloth. $2.50.

Sir Oliver Lodge writes informally and interestingly of various topics connected with radio, addressing his book to the large army of amateurs. Among the subjects touched upon are broadcasting, the work of the pioneers, the discovery of the waves and the development of radiotelegraphy. The vast range of ether vibrations, the transmission of wireless waves, their peculiarities and the general theory of ether waves are discussed. The second part is concerned with some details that make for efficiency, and the third part gives advice and simple rules for various calculations that the amateur constructor needs.

TELEPHONE COMMUNICATION SYSTEMS.

By Royce Gerald Kloeffler. N. Y., Macmillan Co., 1925. (Engineering science series). 284 pp., illus., diagrs., 9 x 6 in., cloth. $4.50.

This book is intended to give the general information needed for a short college course in telephony and also to supply to the worker in telephony a knowledge of matters outside his own particular work. The text is confined to typical present day apparatus and systems.

TRANSFORMERS FOR SINGLE AND MULTIPHASE CURRENTS.

By Gisbert Kapp. 3rd edition revised by Reginald O. Kapp. N. Y., Isaac Pitman & Sons, 1925. 391 pp., illus., diagrs., plates, 9 x 6 in., cloth. $4.50.

In the last edition of this book, issued in 1908, the late Gisbert Kapp spoke of a 3500 kv-a. transformer as "one of the largest made." Today, 60,000 kv-a. transformers are in service. During the interval there has also been great development in construction, insulation and accessories, and many special types for special purposes have been introduced.

In order to keep the book of reasonable size, the reviser has had to confine himself to selected aspects of the subject. In his selection he has kept in mind the needs of students of electrical engineering and of electrical engineers in general rather than those of specialists in transformer design and those interested in the mathematics of the transformer.

The new edition omits some material on the general theory of electricity and on matters no longer of chief importance. More space has been devoted to construction, installation and maintenance. The chapters on design have been revised and new chapters on structural details and on potential and current transformers have been added.

PRINCIPLES OF SOUND SIGNALLING.

By Morris D. Hart and W. Whately Smith. Lond., Constable & Co., 1925. 139 pp., 9 x 6 in., cloth. 12/6. New York, D. Van Nostrand Company.

This book is mainly concerned with the examination of the conditions under which any required acoustical effect may be produced with the minimum expenditure of power. The treatment is theoretical, the object being to identify the factors that affect the efficiency of an acoustical system and to determine the sense in which each operates, so that it will be possible to formulate conditions for an efficient system. The authors discuss in detail the processes of sound production, transmission and reception, and the selection of the most satisfactory combination of these elements.

Past Section and Branch Meetings

SECTION MEETINGS

Akron

Philo Generating Station of the Ohio Power Company, by J. A. Bergin, Superintendent of Operation. Illustrated with slides. January 16. Attendance 90.

Boston

Latest Design and Practise in Power Plants, by V. E. Alden, Consolidated Gas, Elec. Lt. & Power Co. Joint meeting with A. S. M. E. January 14. Attendance 180.

Cincinnati

Progress in Design of Steam Turbines, by D. S. Brown, Union Gas and Electric Co., and

The New York-Chicago Telephone Cable, by J. J. Pilloid, American Telephone and Telegraph Co. Illustrated with slides and motion pictures. A demonstration showed effects which occur in the cable. January 14. Attendance 234.

Cleveland

The Engineer in Business, by S. M. Vauclain, Baldwin Locomotive Works. Joint meeting with Association of Iron and Steel Electrical Engineers, A. S. C. E., A. S. M. E., A. I. M. E. and Society of Industrial Engineers. January 21. Attendance 450.

Connecticut

Maintenance of Industrial Equipment, by F. D. Hallock, Westinghouse Elec. & Mfg. Co. January 19. Attendance 85.

The Quest of the Unknown, by Professor H. B. Smith. Illustrated with slides. January 29. Attendance 60.

Denver

Superpower, by T. R. Cuykendall;

The Photo-Electric Cell as a Photometer, by Stuart Ellis, and

Low-Intensity Photometry, by Dr. Reuben Nyswander, University of Denver. January 15. Attendance 36.

Erie

Mechanical Power and the Trend of Civilization, by C. E. Skinner, Westinghouse Elec. & Mfg. Co. January 19. Attendance 65.

Indianapolis-Lafayette

The Design, Manufacture and Test of Extra High Voltage Bushings, by Prof. C. Francis Harding, Purdue University. December 11. Attendance 33.

Recent Interesting Features in the Industrial Heating Field, by W. S. Scott, Westinghouse Elec. & Mfg. Co. February 5. Attendance 39.

Kansas City

The Application of Electricity to the Medical and Surgical Profession, by E. A. Monroe, Rosenthal X-Ray Co., and

The Indictment Against the Electrical Engineer, by B. J. George, Kansas City Power & Light Co. December 7. Attendance 19.

Application of Switching Equipment from Economical Standpoint, by J. H. Starr, Condit Electrical Mfg. Co. Illustrated with slides. January 18. Attendance 34.

Lehigh Valley

Research of Today, the Engineering of Tomorrow, by E. B. Craft, Bell Telephone Laboratories, Inc. January 20. Attendance 118.

Los Angeles

The Local Telephone Problem, by N. R. Powley, Southern California Telephone Co., and

Development and Research by Bell Telephone Laboratories, by M. B. Long, Bell Telephone Laboratories, Inc. Illustrated with stereoptican. A dinner preceded the meeting. February 2. Attendance 133.

Lynn

Inspection trip to the *Boston Globe*. December 12. Attendance 110.

Inspection trip to the South Boston Dry Dock. January 16. Attendance 250.

The Latest Design and Practises in Power Plants, by V. E. Alden, Consolidated Gas, Elec. Lt. & Power Co. Illustrated with slides. January 13. Attendance 68.

Bullets, by Dr. P. P. Quayle, U. S. Bureau of Standards. Illustrated with slides. January 26. Attendance 68.

Madison

Water Power Development with Special Reference to Automatic Generating Stations, by C. V. Seastone, Consulting Engineer. Joint with University of Wisconsin Branch. January 13. Attendance 50.

Mexico

Railroad Electrification, by E. Cox, General Electric Co. January 7. Attendance 31.

Meters, by Scott Lynn, Sangamo Meter Co., and G. Solis Payan. February 4. Attendance 25.

Minnesota

Dinner Dance. Joint with Engineers Society of St. Paul, Engineers Club of Minneapolis and the A. S. M. E. November 21. Attendance 300.

New High Bridge Station, St. Paul, by J. A. Colvin, Northern States Power Co. After the meeting an inspection trip was made through the plant. February 1. Attendance 100.

Philadelphia

Automatic Control Equipment, by Engineers of the Cutler Hammer Mfg. Co., General Electric Co. and Westinghouse Electric & Mfg. Co. Illustrated. January 11. Attendance 165.

Pittsburgh

The Invisible Service of Science, by Dr. M. I. Pupin, National President, A. I. E. E., and

Giant Power, by Dr. Farley Osgood, Past President, A. I. E. E. A dinner preceded the meeting. January 8. Attendance 368.

Pittsfield

The Electron Theory, by Dr. Saul Dushman. January 12. Attendance 80.

Analogies in Mechanics and Electricity, by Professor W. S. Franklin, Mass. Inst. of Tech. In the afternoon preceding this meeting Professor Franklin spoke to 600 ladies who were guests of the Pittsfield Section. January 19. Attendance 300.

Electric Welding, by R. E. Wagner, General Electric Co. The lecture was illustrated by actual welding, samples of various welding processes and by slides. January 26. Attendance 250.

The Pallotrope, Pallophotophone and the Panatrope, by C. A. Hoxie, General Electric Co. February 2. Attendance 520.

Portland

The Transmission of Photographs over Telephone Wires, by M. B. Long, Bell Telephone Laboratories. January 20. Attendance 150.

Rochester

Superpower, by R. M. Searle, Rochester Gas and Electric Corp. January 8. Attendance 100.

San Francisco

Mechanical Appliances in Line Erection, by J. A. Koontz, Great Western Power Co. Illustrated with moving pictures. A dinner preceded the meeting. January 15. Attendance 155.

Electrical Relays and Their Application, by E. H. Bancker, General Electric Co. Illustrated. January 29. Attendance 155.

Schenectady

Harnessing the Tides in the State of Maine, by Dexter Cooper. December 11. Attendance 400.

Mercury-Arc Rectifiers, by D. C. Prince. Illustrated with slides. January 8. Attendance 260.

Seattle

The Plant of the Seattle Cedar Lumber Company, by G. T. Thirsk. Illustrated with slides and moving pictures. November 18. Attendance 135.

The Preliminary Report of the Skagit Engineering Commission, by Major Joseph Jacobs, Chairman, S. B. Hill and W. C. Morse. Discussion followed. Joint meeting with A. S. C. E., A. S. M. E. and A. I. M. E. A dinner preceded the meeting. December 14. Attendance 250.

The Problems Confronting the Port of Portland, by J. H. Polhemus and Robert Kalim. January 20. Attendance 53.

Sharon

Long-Distance Radio, by S. M. Kintner, Westinghouse Electric & Mfg. Co. February 2. Attendance 175.

Southern Virginia

Power Development in Virginia, by J. R. Horsley, Water Power & Development Commission;

Rural Electrification, by Dr. C. E. Seitz;

Flood Control, by Dr. W. A. Nelson, and

The State Port of Hampton Roads, by members of State Port Commission. January 15. Attendance 71.

Spokane

Electrical Transmission of Pictures, by M. B. Long Bell Telephone Laboratories, Inc. January 13. Attendance 60.

Cushman Hydro-Electric Plant, by J. L. Stannard. Illustrated with slides. January 22. Attendance 56.

Syracuse

The Problem of Radio Broadcasting, by C. W. Horn, Westinghouse Electric & Mfg. Co. January 11. Attendance 135.

Better Engineers—Do We Need Them and Can We Get Them?, by W. E. Wickenden, Society for the Promotion of Engineering Education. January 18. Attendance 75.

Toledo

Telephone Projects in Toledo, by V. A. Diggs, Ohio Bell Telephone Co. Illustrated with slides. January 27. Attendance 48.

Toronto

High Voltage Switching and Phase Isolation, by W. R. Huttinger, Electric Power and Equipment Corp. Illustrated with slides. January 15. Attendance 90.

Voltage Regulation of Distribution Systems, by F. F. Ambuhl, Toronto Hydroelectric System. February 5. Attendance 65.

Urbana

Voltage Surges in Transmission Systems, by J. F. Peters, Westinghouse Electric & Mfg. Co. Illustrated. January 20. Attendance 82.

Vancouver

Operation of British Columbia Electric Power System, by J. Teasdale, British Columbia Railway Co. Illustrated with charts, maps, forms, photos, etc. February 2. Attendance 46.

Washington

The Effects of Gases as Used in the Chemical Warfare Service, by Major-General A. A. Fries. Noon-day luncheon meeting. November 24. Attendance 48.

The French Debt Problem, by Dr. H. G. Moulton, Institute of Economics. Joint with A. S. M. E. A dinner preceded the meeting. January 13. Attendance 90.

Ladies Night. February 9. Attendance 102.

Worcester

Application of Electric Heat to the Metal-Working Industry, by W. S. Scott, Westinghouse Electric & Mfg. Co. A dinner preceded the meeting. January 28. Attendance 75.

BRANCH MEETINGS

Alabama Polytechnic Institute

Talk by R. L. Shepherd, *Electrical World*. The following officers were elected: Chairman, C. W. McMullan; Vice-Chairman, J. M. Edwards; Secretary-Treasurer, J. B. Davis; Reporter, W. H. H. Putnam. January 20. Attendance 31.

University of Arizona

Motion picture, entitled "Electric Travelogue," was shown. January 9. Attendance 15.

The Arc Transmitter, by T. L. Carnes. Motion picture, entitled "Something about the Telephone," was shown. January 16. Attendance 18.

Brooklyn Polytechnic Institute

Characteristics of Electromagnetic Clutches, by M. M. Landesberg, student. Illustrated with slides; and

The Organization of the Brooklyn Edison Company, by R. V. Richard. Illustrated with slides. January 14. Attendance 45.

California Institute of Technology

Design and Performance of Auto Start Motors, by E. S. Mendenhall, U. S. Motors Corp. Illustrated with charts. January 8. Attendance 34.

Motion pictures, entitled "An Electric Travelogue," "The Story of an Electric Locomotive," and "Rolling Steel by Electricity," were shown. January 29. Attendance 195.

University of California

Talks by Robert Sibley and Jos. Le Conte. Joint meeting with A. S. M. E. January 20. Attendance 29.

Case School of Applied Science

Lightning Arresters, by K. B. McEachron, General Electric Co. January 12. Attendance 62.

Catholic University of America

Power-Plant Conditions in Florida, by M. J. Idail, Frank Weller Construction Co. January 14. Attendance 30.

University of Cincinnati

Inductive Interference, by Boris Volgovskoy, student. December 17. Attendance 35.

Measurement of Transients for Lightning-Arrester Design, by K. B. McEachron, General Electric Co. January 14. Attendance 65.

Colorado State Agricultural College

Business Meeting. February 8. Attendance 12.

University of Colorado

The Student Training Course of the General Electric Company, by A. S. Anderson. January 6. Attendance 80.

The Work of the Telephone and Associated Companies, by R. B. Bonney, Mountain States Telephone and Telegraph Co. January 23. Attendance 40.

Cooper Union

The Quest of the Unknown, by Professor H. B. Smith, Worcester Polytechnic Institute. February 6. Attendance 120.

Clarkson College of Technology

Talk by Professor Van Housen of the Potsdam Normal School. February 2. Attendance 22.

University of Denver

The Photo-Electric Cell as a Photometer, by Stuart Ellis and Earl Reed, and

Low-Intensity Photometry, by Dr. Reuben Nyswander. Illustrated with slides. January 15. Attendance 48.

Drexel Institute

Correct Amplification for Radio and Public-Address Systems, by G. B. Egge, Bell Telephone Co. Illustrated and demonstrated. January 15. Attendance 64.

University of Florida

Testing the Heat Insulation of "Insulath," by R. D. Ross. January 11. Attendance 8.

Motion picture, entitled "Coal is King," was shown. February 1. Attendance 17.

University of Idaho

Public-Service Commissions, by Marshall Blair; and

Electrical Applications Aboard Ship, by Donald Coons. January 5. Attendance 12.

State University of Iowa

Bakelite, by Frank Wiggins, and

Use of Engineering Library, by Percy Williams. January 13. Attendance 41.

Heaviside

Up-and-Down Movement of the Layer, by S. J. Lambert;

Student Course at General Electric Company, by J. M. Nelson, and

The Instant Heavisidion, by C. E. Woolridge. January 20. Attendance 49.

Business Meeting. The following officers were elected: President, Leon Dimond; Vice-President, L. A. Ware; Secretary-Treasurer, A. C. Boeke. February 3. Attendance 49.

Opportunities for Engineers at Westinghouse, by Fred Homer, and

The Long Span Across the Narrows at Tacoma, by H. G. Cox. February 10. Attendance 43.

University of Kansas

The Radio Conference in Washington, by Professor H. W. Anderson. The following officers were elected: Chairman, K. R. Krehbiel; Vice-Chairman, W. R. Becker; Secretary, K. B. Clark; Treasurer, E. Kietzman. January 7. Attendance 51.

A Trip through the General Electric Company, by C. C. Adams and Ross Parker, General Electric Co. February 4. Attendance 100.

Lafayette College

Oil Circuit Breakers, by R. M. Spurck, General Electric Co. January 14. Attendance 20.

Research and Engineering, by E. B. Craft, Bell Systems Laboratories, Inc. Joint meeting with Engineers Club of the Lehigh Valley and Lehigh Valley Section, A. I. E. E. January 20. Attendance 225.

Massachusetts Institute of Technology

Richmond Station of the Philadelphia Electric Company, by Constantine Bary, student. Illustrated with slides. January 20. Attendance 15.

Michigan State College

Characteristics of Electric Motors, by E. L. Bailey, Cleveland Electric Motor Co. Motion picture, entitled "Mans Conquest of Time," was shown. January 12. Attendance 53.

University of Michigan

Lightning Arresters, by K. B. McEachron, General Electric Co. January 18. Attendance 60.

Engineering School of Milwaukee

A motion picture, entitled "Queen of the Waves," was shown. January 22. Attendance 82.

Missouri School of Mines and Metallurgy

Switchboard Equipment of a Power Station. A motion picture entitled "The Story of the Storage Battery," was also shown. January 14. Attendance 17.

Montana State College

The General Electric Post-Graduate Course in Electrical Engineering, by M. M. Boring, General Electric Co. January 18. Attendance 170.

Opportunities Offered by the Western Electric Company, by C. W. Brotherton, Western Electric Co.; and

Opportunities in the American Telephone and Telegraph Company, by R. B. Bonney, Mountain States Telephone and Telegraph Co. January 25. Attendance 159.

University of Nevada

The Bell Telephone Laboratories, Inc., by M. B. Long. January 26. Attendance 50.

University of North Carolina

Laying a High-Tension Cable, by J. L. Cantwell, Tidewater Power Co. January 18.

The Moncure Steam Plant, by R. F. Stainback. January 28. Attendance 18.

University of Notre Dame

Theory of Rates and System of Metering, by R. H. Anders, Indiana-Michigan Co. January 18. Attendance 30.

Ohio Northern University

Fundamentals, by Professor Berger. January 14. Attendance 17.

Business Meeting. February 4. Attendance 26.

Ohio State University

Various Phases of Engineering, by Professor F. C. Caldwell. January 15. Attendance 110.

University of Oklahoma

Problems Confronting an Engineering Graduate, by W. A. Kitchen, Oklahoma Gas and Electric Co. January 21. Attendance 27.

Oregon Agricultural College

Business Meeting. January 18. Attendance 41.

Business Meeting. February 2. Attendance 35.

Pennsylvania State College

Super-Power, by D. E. Trucksess, J. H. Garbrick, M. S. Longenecker, A. P. Jackel and H. M. Patrick. January 13. Attendance 50.

The Processes of Insulating Copper Wire, by Professor D. L. Markle. A motion picture, entitled "Voice Highways in the Making," was shown. January 27. Attendance 70.

Spectacular Illumination for the Sesquicentennial, by Professor E. B. Staveley. Illustrated with slides; and

Rate Making, by E. Axman. February 10. Attendance 35.

University of Pennsylvania

Fall Dance. November 13. Attendance 100.

Business Meeting. December 18. Attendance 44.

Business Meeting. January 29. Attendance 40.

Business Meeting. February 9. Attendance 45.

University of Pittsburgh

Boiler Tests at Colfax, by R. R. Thorne, student. January 8. Attendance 26

Recent Developments in Boiler Design, by J. H. Crane. January 15. Attendance 30.

The Opportunities Afforded by the Westinghouse Electric & Mfg. Company, by D. S. Templeton. January 22. Attendance 35.

Purdue University

The Lighting Business, by F. H. Talbott, student, and

History of the Incandescent Lamp, by Professor A. N. Topping. Illustrated. February 9. Attendance 70.

Rose Polytechnic Institute

Lightning Arresters and *The Study of High-Speed Transients,* by K. B. McEachron, General Electric Co. January 13. Attendance 47.

Motion picture on Arc Welding was shown. February 11. Attendance 35.

South Dakota State School of Mines

The Development of Electrical Engineering Course, by E. E. Clark;

Valuable Statistics for the Electrical Engineer, by H. M. Johnson; and

Feild for the Electrical Engineers of the Future, by Professor J. O. Kammerman. January 19. Attendance 51.

Stanford University

The Different Grades of Brass and Bronze, by G. T. Piersol, American Brass Co. A motion picture, entitled "Brass—From Mine to Consumer," was shown. January 14. Attendance 60.

Smoker. Joint meeting with A. S. M. E. Mr. C. V. Moroney, West Coast Sugar Refining Co., gave a talk on Organization and Management. Short talks on Engineering were also given by Professor H. J. Ryan and Professor G. H. Marx. February 3. Attendance 100.

Swarthmore College

Steam Generation and Superheat, by W. H. Berry. February 11. Attendance 35.

Syracuse University

The Inverter, by F. A. Lewis. January 6. Attendance 17.

University of Utah

Accepting Engineering Responsibilities, by Lafayette Hanchet, Utah Light and Power Co. Joint meeting with Engineering Society of the University of Utah, A. S. M. E. and A. S. C. E. February 2. Attendance 523.

Virginia Military Institute

Electricity and Its Relation to Communication, by L. S. Griffith, and

Progress in the Aeronautical Industry, by L. H. von Shilling. February 3. Attendance 47.

Virginia Polytechnic Institute

Insulations, by J. S. Lapp, Lapp Insulator Co. January 15. Attendance 66.

Motion pictures, entitled respectively "The Life of Thomas Edison" and "The Revelations of the X-Ray," were shown. January 25. Attendance 300.

Advantages of the Electric over the Steam Road, by F. S. Oliver, student; *The Value of Individual Thought*, by L. B. Proctor, student; *The Duofold Oscillograph*, by H. J. Harris, student, and *Short Wave Transmission*, by E. D. Gray, student. January 27. Attendance 45.

University of Virginia

A motion picture, entitled "A Romance of Rails and Power," was shown. February 1. Attendance 20.

University of Wisconsin

Water-Power Development and Automatic Stations, by Mr. Seastone, Consulting Engineer. Illustrated with slides. January 13. Attendance 45.

Worcester Polytechnic Institute

Hydroelectric Plants of the New England Power System, by W. R. Bell, New England Power Co. Illustrated with slides. January 20. Attendance 42.

University of Wyoming

Evolution of the Telephone, by I. W. Bond, Mountain States Telephone and Telegraph Exchange. January 28. Attendance 16.

Engineering Societies Employment Service

Under joint management of the national societies of Civil, Mining, Mechanical and Electrical Engineers cooperating with the Western Society of Engineers. The service is available only to their membership, and is maintained as a cooperative bureau by contributions from the societies and their individual members who are directly benefited.

Offices:—33 West 39th St., New York, N. Y.,—W. V. Brown, Manager.
53 West Jackson Blv'de., Room 1736, Chicago, Ill., A. K. Krauser, Manager.

MEN AVAILABLE.—Brief announcements will be published without charge but will not be repeated except upon requests received after an interval of one month. Names and records will remain in the active files of the bureau for a period of three months and are renewable upon request. Notices for this Department should be addressed to ***EMPLOYMENT SERVICE, 33 West 39th Street, New York City,*** *and should be received prior to the 15th of the month.*

OPPORTUNITIES.—A Bulletin of engineering positions available is published weekly and is available to members of the Societies concerned at a subscription rate of $3 per quarter, or $10 per annum, payable in advance. Positions not filled promptly as a result of publication in the Bulletin may be announced herein, as formerly.

VOLUNTARY CONTRIBUTIONS.—Members obtaining positions through the medium of this service are invited to cooperate with the Societies in the financing of the work by nominal contributions made within thirty days after placement, on the basis of $10 for all positions paying a salary of $2000 or less per annum; $10 plus one per cent of all amounts in excess of $2000 per annum; temporary positions (of one month or less) three per cent of total salary received. The income contributed by the members, together with the finances appropriated by the four societies named above, will it is hoped, be sufficient not only to maintain, but to increase and extend the service.

REPLIES TO ANNOUNCEMENTS.—Replies to announcements published herein or in the Bulletin, should be addressed to the key number indicated in each case, with a two cent stamp attached for reforwarding, and forwarded to the Employment Service as above. Replies received by the bureau after the positions to which they refer have been filled will not be forwarded.

POSITIONS OPEN

ELECTRICAL ENGINEER, particularly interested and experienced in relay and breaker applications and protection problems on larger power systems. Location, Pennsylvania. R-8506.

ENGINEER, with experience in design and installation of power station switching equipment. Must be able to supervise and make schematic diagrams of station layout drawings. Not a drafting job, but requires design ability. Permanent. Opportunity. Apply by letter. Location, Pennsylvania. R-8530-C.

ENGINEER, technically trained for investigation of raw materials. Young man who possesses native interest in work of this nature preferred. Ability to thoroughly analyze problems pertaining to raw materials is essential. Apply by letter, stating qualifications, age, education and salary expected. Location, Illinois. R-8535-C.

ENGINEER, technically trained, with some knowledge of accounting, must write good English and be qualified for analytical work in cost and rate department. Apply by letter and enclose photograph. Location, New York. R 8722.

ENGINEER, over 35, the executive and financial experience, for general management in electrical contracting firm. Must be capable financier. May take financial interest. Salary nominal but with participation in profits. Location, New York. R-7874.

MEN AVAILABLE

GRADUATE M. E. and E. E., age 36, wide range of engineering experience, and especially well qualified in public utility electrical engineering, power plants, substations and lines. Highly trained technically, but prefers a position requiring a combination of technical and executive ability. Now employed. B-5842.

ELECTRICAL ENGINEER, Canadian, married, age 46. Graduate McGill University. Long experience electrical and mechanical sales, also operation and construction. Desires position management or sales but consider operation or construction. Absolutely reliable, active, capable handling men. Best references. C-837.

ELECTRICAL ENGINEERING TEACHER desires research position in New York City. Salary required $4000 per annum. Graduate 1917, master's degree 1923. Four years' teaching of electrical engineering subjects, two years with public utility. Lieutenant Signal Corps U. S. B-82.

ENGINEERING EXECUTIVE, age 35, married, graduate electrical engineer. At present assistant to chief executive well known electric utility, desires executive position, department head or local manager with holding company. Present duties consist of handling budget, construction orders, scheduling, expediting and following major construction, as well as miscellaneous management, personnel problems. Capable design engineer with consulting experience. B-754.

ELECTRICAL TECHNICAL GRADUATE, age 36, married, eighteen years' experience electrical design, construction, operation ofc entral stations, substations and transmission lines. Responsible experience specifications and purchase negotiations. Capable of handling the electrical phase of central stations from inception to commercial operation. Design, construction or operation acceptable. Location immaterial but minimum travel desirable. B-2511.

YOUNG MAN, age 27, E E. and A. M. with several years' teaching and some radio laboratory experience, would like teaching or laboratory position. Work in physics or electricity desired. Available on short notice. B-3411.

ELECTRICAL ENGINEER, age 39, sixteen years' supervision design, installation, maintenance, operation various kinds electrical work large

railroad; lighting, motors, distribution, transmission (including submarine cables), substations, power plant electrical apparatus, meter surveys, etc. Desires connection with industrial in charge electrical activities, utility, or electrical sales work. Central or South location. Salary $4200 up, depending on conditions and location. B-9772.

ELECTRICAL ENGINEER, age 38, married, eight years' experience in design and drafting, checking of electrical stations and substations, two years of squad leader assistant, four years installation and operation of storage batteries, rotary converters, transformers, generators, etc. Speaks' Spanish and French. Available on two weeks' notice. C-403.

ELECTRICAL ENGINEER, age 37, desires position as power or plant engineer with large industrial concern. Fifteen years' experience industrial plant layout, installation, maintenance. Thorough knowledge all plant problems including power application, industrial lighting, heating, ventilation and air conditioning. Available immediately. Preferable location, New England States, but will consider other locations. B-5326.

CHIEF-SUPERVISING OR CONSULTING ENGINEER, thirty-five years mechanical and electrical engineering, electric railways, public utilities, engineering and industrial companies, planning and execution several steam railroad electrifications, rehabilitation steam plants, chemical process development, public utility valuations and economic reports, electrolysis research, power transmission. Railway or industrial engineering preferred. Available soon. Employed. B-3246.

ELECTRICAL GRADUATE, of Purdue University, age 28, single, one year General Electric Company test and one year industrial control engineering with General Electric Company. Two years' control experience with large light and power company. Finished Alexander Hamilton Institute Modern Business Course. Desires position in control engineering or sales. Salary $225 a month. C-890.

ELECTRICAL CONSTRUCTION ENGINEER, age 38, wide experience electrical construction, operation. Ten years construction, eight years general superintendent of railways, power plants, substations, general utility work. At present on contract for electrical construction, foreign service. Prefers connection large electrical concern as representative in Latin countries. Technical training. Speaks Spanish, English. Available after six months. C-886.

ELECTRICAL ENGINEER, graduate of Purdue University, age 31, three years General Electric test and engineering departments, three years in substation design with large public utility company. Desires position with consulting engineer, public utility or manufacturing company. Salary $2500. Available on reasonable notice. C-920.

ELECTRICAL ENGINEERING GRADUATE, five years out of college, having had experience in testing, switchboard engineering, indoor and outdoor substation layouts, transmission and distribution. Desires position in engineering work. B-8622.

ELECTRICAL ENGINEER, age 28, technical graduate, desires position with public utility, preferably in the Middlewest. One and one-half years G. E. test, four years' distribution engineering experience with public utility in East. Available on two weeks' notice. B-9040.

INDUSTRIAL ELECTRICAL ENGINEER, wide experience design, installation maintenance of electrification as applied to industrial plants, including power houses, substations, high and low voltage distribution and general motor and control applications. Desires position with large industrial concern as electrical engineer, or power superintendent. University graduate, 36, married. Available on reasonable notice to present employer. B-9113.

WANTED. Position as general superintendent, or district manager of public utility by graduate electrical engineer with ten years' varied experience; construction, maintenance, operation; power plants, substations, transmission and distribution systems, commercial and rate work. B-9480.

ENGINEERING EXECUTIVE, age 39, varied experience, technical graduate. Was machinist, inspector, foreman, engineer, superintendent in charge of 700 men. With present concern sixteen years. Had charge production, shop equipment. Designed, installed numerous labor saving devices, machine tools. Expert on application electric motors, other electric devices for special machinery. Desires sales engineering or executive position. B-8153.

ELECTRICAL ENGINEER, age 28, single, wishes position as executive or assistant electrical engineer. Good character, pleasing personality. German, English, French. Familiar theory and practice electrical and scientific measurements, electrical instruments, meters, relays. Transmission, distribution, protection, dielectric circuits. Three years research laboratory, two years designing. Location, preferably New York. Minimum salary $3500. Available on month s notice. C-930.

GRADUATE ELECTRICAL ENGINEER, 30, single, experience operation, maintenance power plants, substation design, construction work. Calculation of generators motors, transformers for special purposes. Chief of testing department. Specialties: rectifiers, mercury vapour (Brown Boveri Company) for high power, thermionic rectifiers for high voltages. Desires permanent connection public utility, or electrical consulting organization. Available on month s notice. C-924.

EXECUTIVE OR MANAGER, age 43, married, eighteen years' electrical experience: successful in organizing and directing international engineering service. Qualified for and desires position requiring greater responsibility. Salary $10,000. Any location, although slight preference South or Middlewest. B-122.

GRADUATE ELECTRICAL AND MECHANICAL ENGINEER with ten years' experience in electrical testing, drafting and designing, also two years' shop experience as department head. Desires permanent position along above lines or similar at reasonable starting salary with good future. Age 37, married. Location preferred, Ohio. C-374.

EDITOR, age 31, married, university journalistic education, and twelve years' practical experience as associate editor, co-publisher-editor, and managing editor of radio and technical publications, including trade paper. Editor and author of numerous technical papers, magazine articles and books. Available within three weeks. Location, New York. C-829.

ENGINEER, age 37, married, over fifteen years' experience industrial and power plant organization, design and operation, transmission, group substations, layout, equipment, valuation, costs. Has some financial backing to interest in a conservative utility Full time salary $7500. Location in or about New York, and the East. B-8863.

ASSISTANT ENGINEER, age 24, single, B. X. degree in electrical engineering, two years as assistant engineer with valuation department of California State Railroad Commission. Desires work with consulting engineer, or manufacturer in power, or industrial electrical field. Location, Pacific Coast. Available immediately. C869 1-A-42.

VALUATION ENGINEER specializing in reports, inventories and appraisals of public utilities and industrial plants. Formerly with New York State Public Service Commission. Good working knowledge of Spanish. Available on two weeks' notice. Salary $300 per month and expenses. B-9636.

MEMBERSHIP — Applications, Elections, Transfers, Etc.

ASSOCIATES ELECETD FEBRUARY 9, 1926

ABE, TOKUSABURO, Manager, Elec. Dept., Japanese Government Railways, Metropolitan Bldg., 1 Madison Ave., New York, N. Y.

ADAM, ARMAND OTTO, Jr., Telephone Engineer, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.; res., Newark, N. J.

*ADKINS, ALONZO HOWARD, Railway Salesman, Electric Storage Battery Co., 1823 L St., N. W., Washington, D. C.

*AHRLING, GEORGE ALBERT, Appraisal Engineer, Murrie & Co., Inc., 45 E. 17th St., New York, N. Y.; res., Palisade, N. J.

*AIKINS, NELSON BROWN, Transmission Tester, New England Tel. & Tel. Co., Portland; res., South Windham, Maine

ALEXANDER, GEORGE HUGH WEBB, Plant Engineer, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.

ALEXANDER, ROBERT, Jr., Inspector, Murrie & Co., 45 E. 17th St., New York, N. Y.

*ALLEN, JOHN PAYTON, Transmission Engineer, New York Telephone Co., 309 Washington St., Newark; res., Peapack, N. J.

ALLISON, DONALD CAMERON, Asst. Manager, General Electric, S. A., Mexico, D. F., Mex.

*ANDEM, KENNETH SHERWOOD, Engineering Assistant, Public Service Production Co., 86 Park Place, Newark, N. J.

*ANDERSON, ALBERT SIGFRID, Distribution Engineer, New Orleans Public Service Inc., 823 Union St., New Orleans, La.

*ANDERSON, ELMER WEBSTER NATHANALL, Asst. Engineer, Virginia Northern Power Co., Warrenton, Va.

*ARNOLD, OTTO BERNARD, Proposal Engineer, Switchboard Dept., General Electric Co., Schenectady, N. Y.

ASCHMAN, GEOFFREY DONALD, Elec. Engg. Cadet, Public Works Dept., Shannon, N. Z.

ASPLUND, CLIFFORD D., Electrician, Construction Dept., Consumers Power Co., Battle Creek; for mail, Ironwood, Mich.

AUER, GEORGE, Telephone Engineer, Automatic Electric, Inc., 1033 W. Van Buren St., Chicago, Ill.

*BAER, HERBERT JACOB, Distribution Engineer, Metropolitan Edison Co., 141 S. 7th St., Reading, Pa.

BAILY, FRANCIS ARTHUR ALBERT, Test Engineer, Canadian Marconi Co., 173 William St., Montreal, P. Q., Can.

*BARBER, HIRAM W., Jr., Student Engineer, General Electric Co., Lynn; res., West Lynn, Mass.

BARLEY, THOMAS TRUSSELL, Meter Dept., Public Service Electric & Gas Co., 375 Lakeside Ave., Orange; res., East Orange, N. J.

BARRINGER, FRANKLIN D., Pratt Institute, Brooklyn, N. Y.

BARTHELD, LESLIE PETER, Telephone Engineer, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.

BARTHOLOMEW, HERMAN GERARD, New York Telephone Co., 366 E. 150th St., New York, N. Y.

*BATT, LEWIS THEODORE, Cadet Engineer, Public Service Electric & Gas Co., 80 Park Place, Newark; res., South Orange, N. J.

*BAUMGARTEN, ADOLPHE JOHN, Graduate Student, Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.; res., Washington, D. C.

*BAXANDALL, FRANK MATTHEW, Engineer, Commonwealth Power Corp. of Michigan, 244 Michigan Ave., W., Jackson, Mich.

*BAXTER, LAWRENCE HENRY, Meter Engineer, Hydro Electric Power Commission of Ontario, 190 University Ave., Toronto, Ont., Can.

*BAYERS, CHARLES, Station Tester, Brooklyn Edison Co., Inc., 14 Rockwell Place, Brooklyn; res., Winfield, N. Y.

BEDI, HARKISHAM, SINGH, Substation Operator, Public Service Co. of No. Illinois, 72 W. Adams St., Chicago, Ill.

*BELLER, C. J., Operator, Cleveland Electric Illuminating Co., 313 Illuminating Bldg., Cleveland, Ohio.

BERGEN, PHILIP VOLZ, Electrical Inspector, Bronx Gas Electric Co., 43 Westchester Sq., Bronx, New York, N. Y.

BITTERLI, JOHN ALFRED, Draftsman, Inside Plant Engg. Dept., Commonwealth Edison Co., Chicago, Ill.

BIXBY, OSCAR MERRILL, Asst. Engineer, New York Central Railroad, 466 Lexington Ave., New York, N. Y.

BLOCKLIN, H. G., Telephone Engineer, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.

BLUMSTEIN, GUSTAVE, Electrician, Pullman Car Co., Sunnyside Yard, Long Island City; res., New York, N. Y.

BOLSTAD, ARCHIE LEONARD, Sub-Foreman, Installation Dept., Western Electric Co., 523 White Bldg., Seattle, Wash.

BORGE, WILLIAM PETTERSEN, Illinois Power & Light Corp., 231 S. La Salle St., Chicago, Ill.

SIMMONS, ORIE J., Electrical Engineer, Fairbanks-Morse Elec. Mfg. Co., 21 & Northwestern, Indianapolis, Ind.

SIMON, HENRY O., Equipment Engineering Checker, Western Electric Co., Hawthorne Sta., Chicago, Ill.

SIMPSON, PHILIP H., Sales Manager, Eastern Dist., Gould Coupler Co., 250 Park Ave., New York, N. Y.

SKRODER, CARL E., Instructor, Elec. Engg. Dept., University of Illinois, Urbana, Ill.

*SLATER, FRANCIS ROBERT, Student, Elec. Engg. Dept., Oregon Agricultural College, Corvallis; res., Portland, Ore.

SODERBERG, E. W., Draftsman, Pacific Gas & Electric Co., 447 Sutter St., San Francisco; res., Berkeley, Calif.

SOGGE, RICHARD CHARLES, Administrative Div., Central Station Dept., General Electric Co., 1 River Road, Schenectady, N. Y.

*SOVITZKY, WALTER V., Efficiency & Time Study Engineer, Pawling & Harnischgeger Co., 38 E. National Ave., Milwaukee, Wis.

*SPAULDING, JOHN NORMAN, Hydrographer, Great Western Power Co., 530 Bush St., San Francisco; res., Oakland, Calif.

SPICER, FLOYD O., Radio Engineer, Radio Corp. of America, 233 Broadway, New York, N. Y.

*SPRING, ERNEST WALKER, Operating Dept., The Detroit Edison Co., 2000 2nd Ave., Detroit, Mich.

STANDISH, GERALD, Engineer of Surveys, Bronx Gas & Electric Co., 43 Westchester Sq., New York, N. Y.

*STASTNY, JOHN FRANCIS, Electrical Designer, International Harvester Co., Blue Island & Oakley Aves., Chicago, Ill.

STEWARD, HAROLD RAYMOND, Asst. Test Engineer, East Penn. Electric Co., Fishbach Substation, Pottsville; for mail, Summit Hill, Pa.

STEWART, ASA WILLIAM JOHN, Dist. Manager, Toronto Hydro-Electric System, 225 Yonge St., Toronto, Ont., Can.

*STEWART, HERBERT R., General Engineer, Westinghouse Elec. & Mfg. Co., East Pittsburgh; res., East Liberty, Pa.

STONE, EDWARD G., Foreman, Hat Creek Power Houses, Mt. Shasta Power Corp., Cassel, Calif.

SYLER, R. E., Supervisor of Long Lines, Mountain States Tel. & Tel. Co., Denver, Colo.

*TANG, KWAN YAU, Instructor, Elec. Engg. Dept., Ohio State University, Columbus, Ohio.

TATE, WILLIAM, Supt. of Electrification, Mexicana Railroad, Maltrata, Vera Cruz, Mex.

*TECKLENBURG, HERBERT C., Junior Electrical Engineer, New York & Queens Electric Light & Power Co., Lawrence & Grove Sts., Flushing; res., Bay Shore, N. Y.

TERRY, DONALD M., Telephone Engineer, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.

*THIELMAN, JOSEPH A., Inspector, Station Elec. Constr. Dept., Philadelphia Electric Co., 1000 Chestnut St., Philadelphia, Pa.

*THOMAS, JAMES WILLIAM, Student, Johns Hopkins University, 1730 Calvert St., Baltimore, Md.

THOMAS, OSCAR J., Supervisor of Radio, Pennsylvania Power & Light Co., 117 E. Broad St., Hazleton, Pa.

THOMPSON, ALBIN JAMES, Engineer, The Pacific Tel. & Tel. Co., 140 New Montgomery St., San Francisco, Calif.

THOMPSON, ARTHUR WILLIAM, Mechanical Engineer, Engg. Dept., Drafting Div., Westinghouse Elec. & Mfg. Co., Sharon, Pa.

THORUD, ERLING, Electrical Designer, Adirondack Power & Light Corp., 248 Clinton St., Schenectady, N. Y.

*TOMLINSON, FENIS R., Transformer Dept., General Electric Co., 1133 E. 152nd St., Cleveland, Ohio.

TOUSEY, CLARENCE HINCKLEY, Substation Inspector, The Detroit Edison Co., 2000 2nd Ave., Detroit, Mich.

*TOWERS, RICHARD ANTHONY, Metro-Goldwyn-Mayer Corp., Culver City; for mail, Oakland, Calif.

*TRACY, HAROLD HUDSON, Instrument Man, Oregon Short Line Railroad Co., Pocatello, Idaho; res., Salt Lake City, Utah.

*TROY, JOHN REDMOND, Inspector, Murrie & Co., 45 E. 17th St., New York; res., Brooklyn, N. Y.

TRUE, JOHN GEORGE, Draftsman, Tampa Electric Co., Tampa, Fla.

TUCKER, REXFORD S., Electrical Engineer, American Tel. & Tel. Co., 195 Broadway, New York, N. Y.

*TUDOR, RICHARD DeBOSE, Installer, Western Electric Co., 800 14th St., Denver, Colo.

TUTTLE, CHARLES MALLARD, General Storekeeper, General Electric Co., Bridgeport, Conn.

UNDERHILL, WILLIAM LESLIE L., Engineer in Charge, Langley Substation, British Columbia Electric Railway Co., Coghlan, B. C., Can.

UTTER, RAYMOND EDWARD, Asst. Elec. Engineer, Union Gas & Electric Co., 1107 Plum St., Cincinnati, Ohio.

*VACLAVIK, FRANK JOSEPH, Engineer, Commonwealth Power Corp.; Consumers Power Co., 244 W. Michigan Ave., Jackson, Mich.

VALENTINE, CLIFFORD W., Sales Assistant, Westinghouse Elec. & Mfg. Co., 150 Broadway, New York; res., Brooklyn, N. Y.

*VAN WYK, H., Meter Tester, Puget Sound Power & Light Co., 7th & Olive, Seattle, Wash.

VELASCO, LUIS RAIMUNDO, Operator, Maltrata Substation, Mexican Railroad Co., Vera Cruz., Mex.

*VOGELSANG, LEWIS OSCAR, Engineer, San Antonio Public Service Co., 201 N. St. Marys St., San Antonio, Texas.

VOSS, HOWARD MADEIRA, Field Man, So. California Telephone Co., 433 S. Olive St., Los Angeles; res., Gardena, Calif.

WADSLEY, CHARLES RAYNOR, Telephone Engineer, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.

*WAITE, ROGER THORNTON, Engineer, Research Dept., Aetna Life Insurance Co., Hartford, Conn.

*WALIGOSKI, ADAM ARNOLD, Equipment Engineer, Western Electric Co., Hawthorne Sta., 48th & 22nd Ave., Chicago, Ill.

WALKER, JOHN JOSEPH R., Asst. Dept., Supervisor, Western Electric Co., 268 W. 36th St., New York, N. Y.

*WALKER, SAMUEL WEYLIE, Inspector, Canadian National Railways, New Union Station, Toronto, Ont., Can.

WEBB, WALTER RAY, Electrical Engineer, Worthington Pump & Machinery Corp., Laidlaw Works, Elmwood Place, Hamilton Co., Ohio.

WEBER, CARL W., Electrical Contractor Engineer, Western Electric, 410 W. 43rd St., Kansas, Mo.

WEINER, WILLIAM, Electrical Inspector, Pennsylvania Railroad Co., Sunnyside Engine House, Long Island City, N. Y.

WESTIN, CARL HAROLD, Diagram Engineer, Westinghouse Elec. & Mfg. Co., East Pittsburgh; res., Pittsburgh, Pa.

WILLIAMS, FRANCIS A., Dept. Head, Western Electric Co., Inc., 395 Hudson St., New York, N. Y.

*WILLIAMS, STUART ROBERT, Special Representative, Westinghouse Elec. & Mfg. Co., South Bend, Ind.; for mail, Chester, Pa.

WILLS, ARTHUR LLOYD, Engineer, General Electric Co., 1301 Pierce Bldg., St. Louis, Mo.

WITHROW, CHARLES HUNTER, Telephone Engineer, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.

WURTH, CHARLES G., Supervising Methods Engineer, Western Electric Co., Inc., 268 W. 36th St., New York, N. Y.

*YARMACK, JOHN EREMEI, Asst. Instructor Elec. Engg. Dept., Yale University, 10 Hillhouse Ave., New Haven, Conn.

ZUCCO, JOHN JOSEPH, New York EdisonCo., 327 Rider Ave., New York, N. Y.

Total 382

*Formerly enrolled students.

ASSOCIATES REELECTED FEBRUARY 9, 1926

CARR, CHARLES CLEMENT, Telephone Engineer, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.

CHANDLER, MAX, Engineering Dept., Commonwealth Power Co., Jackson, Mich.

MARCHANT, LEWIS, Traffic Manager, D. P. Robinson & Co., 125 E. 46th St., New York, N. Y.; res., Wilton, Conn.

MARSTELLER, GEORGE F., Electrical Designer, Calculator, C. H. Tenney & Co., 200 Devonshire St., Boston, Mass.

PENMAN, ROY FRANKLIN, Instructor, Elec. Engg. Dept., Cornell University, Franklin Hall, Ithaca, N. Y.

SCHAEFER, JOSEPH HARVEY, Equipment Engineer, New York Telephone Co., 158 State St., Albany, N. Y.

SMITH, E. DARWIN, Jr., Secretary & Electrical Engineer, Rochester Electric Products Corp., 640 Driving Park Ave., Rochester, N. Y.

STEINMETZ, RICHARD BIRD, Sales Correspondent, Westinghouse Elec. & Mfg. Co., 150 Broadway, New York; res., Brooklyn, N. Y.

TINKEY, OTTO G., Foreman of Construction, Ideal Electric Co., Champaign; res., Urbana, Ill.

MEMBERS ELECTED FEBRUARY 9, 1926

BURRIER, EARL ROSCOE, Colliery Electrical Engineer, Hudson Coal Co., Scranton, Pa.

BUSHMAN, ANDREW KIDD, Engineer, General Electric Co., 230 S. Clark St., Chicago, Ill.

CORAM, ROY EVERETT, Engineer, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.

GOLDSMITH, LESTER M., Consulting Engineer, Atlantic Refining Co., 260 S. Broad St., Philadelphia, Pa.

GRANICH, ALFRED MATHEWS, Telephone Engineer, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.

KECKLER, CHARLES WILLIAM, Telephone Engineer, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.

MARTING, HEBER EDWIN, Member, Technical Staff, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.; res., Rutherford, N. J.

PAINE, LOUIS ARTHUR, Experimental Engineer, Lincoln Meter Co., 72 Stafford St., Toronto, Ont., Can.

PAINTON, EDGAR THEODORE, Chief, Electrical Sales Dept., The British Aluminum Co., Ltd., 109 Queen Victoria St., London, Eng.

PARKER, LEVI WRIGHT, Telephone Engineer, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.; res., East Orange, N. J.

PETERSON, EUGENE, Electrical Engineer, Engg. Dept., Western Electric Co., 463 West St., New York, N. Y.

PLOTNER, LOYD D., Telephone Engineer, Bell Telephone Laboratories, Inc., 463 West St., New York; res., Brooklyn, N. Y.

REICHARD, WADE HAMPTON, Consulting Electrical Engineer, General Railway Signal Co., Rochester, N. Y.

SHILEY, SAM WELLES, Supervisor, Toll System Development, Bell Telephone Laboratories, Inc., 463 West St., New York; res., Port Washington, N. Y.

ZIMMERMAN, JOHN ALEXANDER, Chief Elec. Draftsman, charge of High Tension Trans. Design, Chas. H. Tenney & Co., 200 Devonshire St., Boston, Mass.

FELLOW ELECTED FEBRUARY 9, 1926

HELPBRINGER, J. NELSON, Gen. Supt., Staten Island Edison Co., Staten Island, N. Y.

TRANSFERRED TO GRADE OF FELLOW FEBRUARY 9, 1926

BETTIS, ALEXANDER E., Vice-President, Kansas City Power & Light Co., Kansas City, Mo.

CURTIS, HARVEY L., Senior Physicist, Bureau of Standards, Department of Commerce, Washington, D. C.

DANN, WALTER M., Electrical Engineer, Westinghouse Electric & Mfg. Co., Sharon, Pa.

HOBART, K. E., Superintendent Overhead Lines, Commonwealth Edison Co., Chicago, Ill.

PRINCE, DAVID C., Research Engineer, General Electric Co., Schenectady, N. Y.

TRANSFERRED TO GRADE OF MEMBER FEBRUARY 9, 1926

EWENS, W. SYDNEY, District Manager, Alfred Collyer & Co., Toronto, Ont., Can.

HAZELTINE, HAROLD L., Engineer of Insulation, Sterling Varnish Co., Pittsburgh, Pa.

JOHNSON, EDWARD J., Member of Technical Staff, Bell Telephone Laboratories, New York., N. Y.

MEYER, A. A., Assistant General Superintendent, Detroit Edison Co., Detroit, Mich.

NOSS, MARSENA A., Chief Engineer, International Telepost Co., New York.

ROBINSON, BLIGHT S., Engineer, R. W. Cramer & Co., Inc., New York.

SHEPARD, ROBERT B., Electrical Engineer, Underwriters' Laboratories, New York.

SILSBEE, FRANCIS B., Physicist, Bureau of Standards, Department of Commerce, Washington, D. C.

SINGLETON, L. D., Senior Field Electrical Engineer, Braden Copper Co., Rancagua, Chile.

SMITH, EVERETT H., Supervising Equipment Design Engineer, Bell Telephone Laboratories, New York.

SNIDER, GEORGE E., Chief Electrical Engineer, Ohio Public Service Co., Cleveland, O.

STEVENS, ALEXANDER C., Electrical Engineer, General Electric Co., Schenectady, N. Y.

WEIGHT, JOHN W., Head, Industrial Truck and Locomotive Dept., Electric Storage Battery Co., New York.

WILKINS, ROY, Assistant Engineer, Dept. of Hydro-Elec. & Transmission Engg., Pacific Gas & Electric Co., San Francisco, Calif.

RECOMMENDED FOR TRANSFER

The Board of Examiners, at its meeting held February 5, 1926, recommended the following members for transfer to the grade of membership indicated. Any objection to these transfers should be filed at once with the National Secretary.

To Grade of Fellow

FLEAGER, CLARENCE E., Chief Engineer, Pacific Telephone & Telegraph Co., San Francisco, Calif.

To Grade of Member

CLARK, JOHN A., Research Engineer, Weston Electrical Instrument Corp., Newark, N. J.

CUNNINGHAM, R. E., Operating Electrical Engineer, Southern California Edison Co., Los Angeles, Calif.

DAVIES, HAROLD C., Station Section, Elec. Engineering Dept., Hydro-Electric Power Commission, Toronto, Ontario.

FIELDS, ERNEST S., Asst. Electrical Engineer, Union Gas & Electric Co., Cincinnati, O.

GRAHAM, FRANK B., Telephone Engineer, Bell Telephone Laboratories, New York, N. Y.

HALE, WILLIAM K., State Electrical Engineer, Mountain States Tel. & Tel. Co., Denver, Colo

HARRIS, IRVING C., Consulting Engineer, Cone and Harris, Los Angeles, Calif.

HEALY, EDWIN S., Transmission Engineer, Electric Bond & Share Co., New York, N. Y.

HINSON, N. B., System Planning Engineer, Southern California Edison Co., Los Angeles, Calif.

HORN, A. F. E., Manager, General Electric Co., Washington, D. C.

JOHNSON, JAMES A., Works Manager, Canadian Crocker Wheeler Co., Ltd., St. Catherines, Ont.

JONES, ARTHUR L., District Engineer, General Electric Co., Denver, Colo.

PUBLOW, CEDRIC F., Asst. Station Engineer, Hydro-Electric Power Commission, Toronto, Ont.

SIMPSON, WILLIAM L., Division Engineer, Postal Telegraph-Cable Co., Chicago, Ill.

SOULE, WILLIAM H., Electrical Superintendent, Mond Nickel Co., Coniston, Ont.

STARR, JAMES H., District Engineer, Condit Electrical Manufacturing Co., St. Louis, Mo.

APPLICATIONS FOR ELECTION

Applications have been received by the Secretary from the following candidates for election to membership in the Institute. Unless otherwise indicated, the applicant has applied for admission as an Associate. If the applicant has applied for direct admission to a higher grade than Associate, the grade follows immediately after the name. Any member objecting to the election of any of these candidates should so inform the Secretary before March 31, 1926.

Abbott, H. H., American Tel. & Tel. Co., New York, N. Y.

Amson, R. I., United Electric Light & Power Co., New York, N. Y.

Axon, W. R., Westinghouse Elec. & Mfg. Co., Philadelphia, Pa.

Axtell, H. B., American Tel. & Tel. Co., St. Louis, Mo.
Baker, A. W., American Electric Railway Association, New York, N. Y.
Baker, H. D., Sales Engineer, 602 Ford Bldg., Detroit, Mich.
Baker, H. W., Bell Telephone Laboratories, Inc., New York, N. Y.
Barden, W. S., Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.
Barnard, G. H., (Member), Electro-Dynamic Co., Bayonne, N. J.
Barton, H. P. S., Jr., Postal Telegraph-Cable Co., New York, N. Y.
Beach, W. C., Bell Telephone Laboratories, Inc., New York, N. Y.
Beck, A. D., Westinghouse Elec. & Mfg. Co., Cleveland, Ohio
Bellis, A. P. S., John A. Roebling's Sons Co., Trenton, N. J.
Bingel, G. H., C. H. Stevens Co., New York, N. Y.
Bird, T. O., Line Material Co., South Milwaukee, Wis.
Black, H. M., Allis-Chalmers Mfg. Co., Milwaukee, Wis.
Blakey, L. M., Hartford Accident & Indemnity Co., Hartford, Conn.
Blois, R. K., (Member), Cons. Mining & Smelting Co. of Can., Ltd., Trail, B. C.
Bloser, W. C., Thomas E. Murray & Co., New York, N. Y.
Bonn, N. E., Leeds & Northrup Co., Philadelphia, Pa.
Bonner, W. F., Public Service Electric & Gas Co., Irvington, N. J.
Boolos, S. G., Brooklyn Edison Co., Brooklyn, N. Y.
Brake, W. J., Light & Power Dept., City of Regina, Regina, Sask., Can.
Braue, C. A., Brooklyn Edison Co., Brooklyn, N. Y.
Bressner, J., Pratt Institute, Brooklyn, N. Y.
Brice, W. A., Illinois Bell Telephone Co., Chicago, Ill.
Brown, E. C., Hartford Electric Light Co., Hartford, Conn.
Brown, E. C., E. C. Brown Co., Boston, Mass. (Applicant for re-election.)
Browne, W. H., 3rd, McCollom Geological Explorations Corp., Chevy Chase, D. C.
Burbidge, L., R. A. Lister & Co., Inc., New York, N. Y.
Burchill, G. H., Canadian General Electric Co., Peterborough, Ont., Can.
Burri, J. J., (Member), Staten Island Edison Co., Staten Island, N. Y.
Buswell, J. F., Westinghouse Elec. & Mfg. Co., Boston, Mass.
Caldwell, E., American Rolling Mill Co., Ashland, Ky.
Camilli, G., General Electric Co., Pittsfield, Mass.
Carey, F. K., Llewellyn Iron Works, Los Angeles, Calif.
Cartland, F. W., Western State Normal School, Kalamazoo, Mich.
Case, J. W., General Electric Co., Schenectady, N. Y.
Caster, J. H., (Member), Hydro-Elec. Pr. Comm. of Ontario, Toronto, Ont., Can.
Castro, L., Jr., General Electric Co., Schenectady, N. Y.
Centeno, J. G., Brooklyn Edison Co., Brooklyn, N. Y.
Charles, D. M., Reliance Elec. & Engineering Co., Cleveland, Ohio
Cheney, M. C., Rockbestos Products Corp., New Haven, Conn.
Chun, H. H., Premier Electric Co., Chicago, Ill.
Clarke, S. O., United Electric Light & Power Co., New York, N. Y.
Coffin, L., Allis-Chalmers Mfg. Co., Milwaukee, Wis.
Cox, B. C., Carter Electric Co., Atlanta, Ga.
Craig, P. H., University of Cincinnati, Cincinnati, Ohio
Cresson, G. V., Public Service Corp. of N. J., Newark, N. J.
Crist, J. A., New York Telephone Co., New York, N. Y.
Crotty, H. F., General Electric Co., West Lynn, Mass.
Cummings, A. E., New York Telephone Co., New York, N. Y.
Daniel, T. A., Western Electric Co., Chicago, Ill.
Davies, W. B., Saskatchewan Telephone System, Saskatchewan, Can.
Dawson, L. L., Erie Railroad Co., Jersey City, N. J.
de Kay, R. D., Bell Telephone Laboratories, Inc., New York, N. Y.
de la Garrigue, J. L., School of Engg. of Milwaukee, Milwaukee, Wis.
Demerec, Mary Z., New York Telephone Co., New York, N. Y.
de Polac, L. C., Westinghouse Elec. & Mfg. Co., New York, N. Y.
De Tar, D. R., General Electric Co., Schenectady, N. Y.
Dettwiller, C. J., Western Electric Co., Inc., Hawthorne Sta., Chicago, Ill.
Dickinson, R. B., Duke Price Power Co., Ltd., Isle Maligne, Lake St. John, P. Q.
Dolton, E. G., (Member), Div. of Architecture & Construction, State of New Jersey, Trenton, N. J.
Donnelly, J. F., Pennsylvania State Sanatorium, S. Mountain, Mont Alto, Pa.
Dua, M. S., Pacific Gas & Electric Co., San Francisco, Calif.
Duvander, B. F. H., Pacific Gas & Electric Co., San Francisco, Calif.
Egli, J., American Brown Boveri Electric Corp., Camden, N. J.
Ellsworth, F. P., Western Electric Co., Inc., New York, N. Y.
Fauerbach, W. F., Westinghouse Elec. & Mfg. Co., New York, N. Y.
Feldman, J. J., Westinghouse Elec. & Mfg. Co., Brooklyn, N. Y.
Forbes, A. H., Pennsylvania State College, State College, Pa.
Franz, A. S., Postal Telegraph-Cable Co., New York, N. Y.
Furbish, C. T., Warren Foundry & Pipe Co., Phillipsburg, N. J.
Garrison, J. D., W. A. Beile & Co., Chicago, Ill.
Gedge, W. J., New York Telephone Co., New York, N. Y.
Goard, L. C., (Member), The Ohio Public Service Co., Ashland, Ohio
Godfrey, J. H., Westinghouse Elec. & Mfg. Co., Springfield, Mass.
Golikoff, A., "Ural-Platinum Trust," New York, N. Y.
Goss, R. C., Ohio Brass Co., Philadelphia, Pa.
Graybrook, H. W., Westinghouse Elec. & Mfg. Co., Springfield, Mass.
Griffin, T. J., Westinghouse Elec. & Mfg. Co., Philadelphia, Pa.
Gunnarson, G. A., Electric Bond & Share Co., New York, N. Y.
Hackbush, R. A., Canadian Westinghouse Co., Ltd., Toronto, Ont., Can. (Applicant for re-election.)
Haga, J., Brooklyn Edison Co., Brooklyn, N. Y.
Hahn, W. C., General Electric Co., Chicago, Ill.
Hanstein, H. B., Brooklyn Edison Co., Brooklyn, N. Y.
Hare, J. G., East York Hydro-Electric Commission, Toronto, Ont., Can.
Harte, J. A., Dept. of Plant & Structures, New York, N. Y.
Henritze, R. J., Westinghouse Elec. & Mfg. Co., New York, N. Y. (Applicant for re-election.)
Hewlett, R. C., Pratt Institute, Brooklyn, N. Y.
Hickcox, T. W., Pratt Institute, Brooklyn, N. Y.
Hill, G. J., Western Electric Co., Inc., Washington, D. C.
Holleman, E. M., Radio Salesman, Germains, Los Angeles, Calif.
Houck, F. J., Erie Railroad Co., Jersey City, N. J.
Howlett, P. W., Sangamo Elec. Co. of Canada, Ltd., Toronto, Ont., Can.
Hughes, A. A., Radio Corp. of America, Rocky Point, L. I., N. Y.
Hunter, R. J., Brooklyn Edison Co., Brooklyn, N. Y.
Inglis, J. G., Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.
Jaczko, J., Westinghouse Elec. & Mfg. Co., Sharon, Pa.
Jones, H. P., Philadelphia Electric Co., Philadelphia, Pa.
Jones, R. W., Consumers Power Co., Flint, Mich.
Judge, F. G., (Member), Pierce Electric Co., Tampa, Fla.
Kaneb, B. M., American Steel & Wire Co., Worcester, Mass.
Keller, E. J., Roxborough High School, Philadelphia, Pa.
Kelly, C. R., K & K Electr Co., Perth Amboy, N. J.
Kenah, R. M., Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.
Kinckiner, R. A., Philadelphia Electric Co., Philadelphia, Pa.
Kinsella, R. H. F., Brooklyn Edison Co., Brooklyn, N. Y.
Krauss, R. A., Counties Gas & Electric Co., Norristown, Pa.
Kray, J. F., Bell Telephone Co. of Pa., Philadelphia, Pa.
Krueger, R. A., Wisconsin Valley Electric Co., Wausau, Wis.
Lambert, A. W., Pacific Tel. & Tel. Co., San Francisco, Calif.
Lederhause, H. W., Bell Telephone Laboratories, Inc., New York, N. Y.
Leeson, G. E., Saskatchewan Gov't. Telephones, Yorkton, Sask., Can.
Leonard, E. M., Pittsburgh Transformer Co., Pittsburgh, Pa.
Levy, M. L., Stromberg-Carlson Tel. Co., Rochester, N. Y.
Lewis, H. G., (Member), Westinghouse Elec. & Mfg. Co., Springfield, Mass.
Lewis, J. G., Potomac Edison Co., Cumberland, Md.
Leyden, A. F., Bell Telephone Laboratories, Inc., New York, N. Y.
Lippincott, C. D., Adirondack Power & Light Corp., Schenectady, N. Y.
Lyster, M. S., The Pacific Tel. & Tel. Co., San Francisco, Calif.

See the January issue for the latest published list. The Institute now has 51 Sections and 86 Branches.

DIGEST OF CURRENT INDUSTRIAL NEWS

NEW CATALOGUES AND OTHER PUBLICATIONS

Mailed to interested readers by issuing companies

Electricity on Battle Ships.—Bulletin GEA-306, 12 pp., entitled "The Electric Fleet." Describes the electrified first line battle ships and airplane carriers in the United States Navy. The General Electric Company, Schenectady, N. Y.

Machine Vibration Isolation.—Bulletin, 12 pp., entitled "How to Isolate Machine Vibrations." Describes Korfund treated cork plates used in foundations to absorb vibration of machinery. The Korfund Co., Inc., 11 Waverly Place, New York.

Motors.—Bulletin 100, 4 pp. Describes squirrel cage induction motors for general purpose applications, ½ to 50 h. p. Bulletin 101, 4 pp. describes fire pump motors, a-c. open and enclosed types, for the operation of direct connected centrifugal fire pumps. Northwestern Manufacturing Company. Milwaukee, Wis.

Insulator Flashover Values.—The Delta-Star Monthly Message (Vol. 2, No. 7) contains an article on standardization giving comparative flashover values on insulators, by M. M. Samuels, which should be of particular interest to designing engineers. The Delta-Star Electric Company, 2400 Block Fulton Street, Chicago, Ill.

Switching Equipment for Alternating-Current Power Stations.—Publication 1541-C, 112 pp. This special publication deals with the general fundamentals that should be borne in mind in laying out a switchboard, and describes in detail the various types of switching equipment. It is profusely illustrated with diagrams and halftone illustrations. Westinghouse Electric & Mfg. Company, East Pittsburgh, Pa.

NOTES OF THE INDUSTRY

The American Steel & Wire Company, Chicago, announces the appointment of H. S. Durant as manager of the Cold Rolled Strip and Spring Sales Department, Chicago, vice Lewis Johnson, deceased.

New Oscillating Fan.—The Wagner Electric Corporation, of St. Louis, has developed and is placing on the market a new three-speed, ten inch, oscillating fan to retail at a popular price.

New Plant for Ajax Furnaces.—The Ajax Electrothermic Corporation, Trenton, N. J., has purchased 25 acres of land on the Reading Railroad where the erection of a new factory has been begun. The company manufactures high-frequency induction furnaces developed by Dr. E. F. Northrup.

The Belden Manufacturing Company, Chicago, announces the appointment of Edward A. Sipp as aviation research engineer for the development of special cables for airplane and similar work. The increased demand for special wiring harnesses or cables for airplane applications has made it necessary for the company to organize a separate department to design and manufacture such products.

Pressed Steel Plate Field Rheostats.—The Ward Leonard Electric Company, Mount Vernon, N. Y. is now building its vitrohm circular-plate generator and motor field rheostats with pressed-steel instead of cast-iron plates. The new design permits lighter and much stronger plate to be supplied for the same duty. Accessories furnish provision for all desirable combinations of plates with direct, concentric or sprocket drive, floor, wall or ceiling mounting, and for front or rear-of-switchboard mounting.

New French Allis-Chalmers Organization.—Allis-Chalmers business in continental Europe will be handled through an organization recently incorporated as Allis-Chalmers (France) with headquarters at 3 rue Taitbout, Paris. H. I. Keen, who has been manager of European sales through the company's district office in P[illegible] the managing director of the new organization. [illegible]s maintained for many years an office in [illegible] House, London Wall, E. C. 2.

Large Street Lighting Contract to Westinghouse.—The Westinghouse Electric & Manufacturing Company has secured an order for 1500 ornamental lighting units to be installed in the Davis Islands, Tampa-in-the-Bay, Florida, a new real estate development. Westinghouse Hollowspun concrete standards will be used. More than 300,000 feet of cable will be required, which will be laid at a depth of twelve inches along the curbway and put down at the same time as the pavement to facilitate construction.

Supplementary Compensation to G. E. Employees.—The sum of $1,367,426 07 was paid in February by the General Electric Company to employees who have been with the company for five years or more. These payments, termed supplementary compensation, represent 5 per cent of each individual's earnings for the six months ending December 31,1925. Payments were made in General Electric Employes' Securities Bonds or cash, as desired. About one-third of the total amount was distributed in the Schenectady works.

Promotions in Hazard Mfg. Company.—The Hazard Manufacturing Company, Wilkes-Barre, Pa., manufacturers of wire rope and electrical cables, announces the appointment of Laurence W. Bevan as general manager. Mr. Bevan entered the employ of the company thirteen years ago as metallurgical engineer. William S. Hart has been appointed special representative in charge of Hazard sales in the oils field of the United States with headquarters in Wilkes Barre. He has been in the employ of the company since 1888. Thomas A. Keefe was appointed district manager of the Chicago branch. Mr. Keefe came to the company in 1913 as a salesman.

Ohio Brass Company Develops New Iron.—The Ohio Brass Company, Mansfield, Ohio, has developed a new metal which it calls "Flecto" iron. This is a type of malleable iron which by virtue of a heat treating process, is freed from all tendency toward embrittlement when hot-dip galvanized. While retaining all of the desirable characteristics of malleable iron, the Flecto process so improves the metal with added valuable properties that it is considered to be practically a new metal. The announcement is made only now, but it is understood that all malleable iron castings produced by this manufacturer during the past two years have been treated by this process, the company having withheld announcement until the metallurgy of this new metal had been thoroughly proved by its use in the field.

The process for making Flecto iron is patented, but is available to other manufacturers under a liberal license arrangement.

Century Electric Expands. The Century Electric Company, St. Louis, Mo., has purchased an eight acre factory site located on a branch of the Wabash R. R. at Spring Avenue, on which it will erect buildings for manufacturing and warehousing. The present factories will be retained. The growth of the Century Electric Company, one of the pioneers in single-phase motor development, has been remarkable. Starting in 1903 in a small building at 1011 Locust Street, the company's factories, of modern construction, now occupy more than eleven acres of floor space, giving employment to over 3,000. The founders of the company are still actively directing all phases of the business. The officers include: E. S. Pillsbury, Prest.; S. M. Jones, and E. W. Collins, Vice-Prests.; R. J. Russell, Vice-Prest. and Secy.; B. M. Whittemore, Treas. and J. L. Woodress, Sales Manager.

The Company has arranged to distribute as a bonus from 1925 earnings, $190,000.00 in the common stock of the company at $120 per share to those of its 3,000 employees who have been connected with the company during the entire year of 1925, and who are still with the company on March 15, 1926. This means that each of those who are entitled to participate will receive at least 7 per cent of his salary or earnings.

The Ideals of the American University*

What, then, is the mission of the American University? Comparing the American college with the American university one is reminded of Janus, the old Roman deity, the guardian of the entrance to the Roman home. In the early dawn of Roman history this deity had one face only, but as the Roman home grew bigger a second face appeared. The American college and the American university are the two faces of the same guardian angel; one face contemplating reverently the familiar past and the other anxiously exploring the unknown future of this nation. The college perpetuates the national idealism of the past, the university prepares its future expansion. This idealism is the bond between the two, and without this bond they lose their spiritual meaning.

Lincoln closed his Gettysburg speech with the following warning:

> "It is rather for us to be dedicated to the task remaining before us . . . . that this nation, under God, shall have a new birth of freedom,—and that government of the people, by the people, for the people, shall not perish from the earth."

A dedication to so exalted a task demanded an expansion of our inherited national idealism. It is not surprising that the generation which heard this warning saw also the birth of the first real American university. The most comforting response to Lincoln's warning was a series of events which should be recorded with red letters in American history. The earliest among these events is the foundation, under a Congressional Charter, of the National Academy of Sciences in the same year in which Lincoln delivered his immortal speech. Lincoln, our greatest idealist in political philosophy, and Joseph Henry, his personal friend, our greatest idealist in science in those days, were the sponsors of this national organization whose members were always devoted to the cultivation of idealism in American learning. Some of the most distinguished members of this organization like Joseph Henry, John William Draper, Frederick Barnard, and Andrew White started that great movement for higher endeavor which found its first visible expression in the foundation of Johns Hopkins University in 1876, the first real university in the United States. Every student of the history of American idealism should know the life of Daniel Coit Gilman, at one time president of the University of California, who became the first president of Johns Hopkins University and presided over a faculty of idealists of the highest order of magnitude.

The aim of these idealists was the cultivation of idealism in every department of American learning, in order to prepare this nation for the expansion of the early American idealism which Lincoln glorified in the first lines of his Gettysburg ode. How did the nation respond? In less than a decade a score of American universities sprang into existence and followed the example of the idealists of Baltimore. This sudden outburst in the higher intellectual activities of our young universities encourages the belief that the period inaugurated by the termination of the Civil War witnessed an Intellectual Renaissance in the United States. The catalogue of its achievements during the last fifty years is as long as Homer's catalogue of the ships which carried the Greek heroes to the plains of Troy. Neither time nor purpose permit its recital here. There is one achievement, however, which I must mention.

Nothing resists a change as obstinately as the mental attitude of man. The history of science from Archimedes to Newton offers many illustrations of this wellknown fact. The change in the mental attitude of our age is one of the greatest achievements of our Intellectual Renaissance. Less than two generations ago educational training was expected by many to operate like a penny in the slot machine, that is, learn your lesson and convert your learning into cash without much delay. The so-called practical man who managed our American industries was at that time an ardent advocate of this utilitarian theory. He worshipped the art of making a living. Franklin and Lincoln, my patron saints, had no sympathy with this theory. The art of making a living was not the determining factor in their schooling, but the art of making life worth living was everything to them. They would find no fault with the American college, because its diploma does not testify that college graduates are loaded with a knowledge of the art of making a living, provided, however, that they carry with them some definite ideas about the art of making life worth living, not only their own individual life but also the life of our nation. The expansion of these ideas is the gospel of the American university. The Philistines, the so-called practical men of two generations ago, could not resist the power of this gospel; they have been converted, and this conversion is a great triumph of the apostles of our American universities.

The idealism of the Christian gospel which St. Paul and St. Peter preached was not clearly understood until the world had seen it in operation in the lives of those who had embraced it. The idealism of the American university was not clearly understood by the so-called practical man until he had seen it in operation in his dearly beloved industries. Motive, mental attitude, and method of work form the tripod upon which this idealism rests. But a motive which means unselfish search of the truth; a mental attitude which demands open minded communion with nature and freedom from prejudice; a method of work which in the hands of men like Archimedes, Galileo, Newton, Faraday and their disciples conferred innumerable blessings upon mankind; all these things were too abstract for the socalled practical man. But presently industrial problems arose the solution of which demanded the subtle touch of the university idealist; the stubby hand of the practical man had tried to handle them and it failed. The idealist showed the way, and from that time on the American industries began to worship at their altar of idealism of the American universities. Today that idealism is their patron saint who guides them in their progress; it will soon perform a similar service in all the activities of our nation, including our national politics, and lead us to that ideal democracy which was the dream of Lincoln.

Your distinguished fellow citizen of California, Secretary Hoover, is a practical man, but he has nothing in common with our practical men of two generations ago. In his recent appeal to this nation he preached a gospel which may be summed up as follows; Cultivate the fundamentals in the research laboratories as well as in the lecture rooms. This will lead us to the truth which will give this nation a new birth of freedom, and will raise our democracy to the lofty level of Lincoln's ideal.

M. I. PUPIN

*Abstract from a Charter Day address delivered at the University of California, March 23, 1926.

Some Leaders of the A. I. E. E.

Ralph Davenport Mershon, the twenty-fifth President of the A. I. E. E. was born in Zanesville, Ohio, July 14th, 1868. He was educated in the public schools of his native place, and began his engineering career at the age of 17 as a member of an engineering corps engaged in railway location and construction. In 1886 he entered the Ohio State University, from which institution he graduated in 1890 with the degree of M. E. During the last year of his University course, he was Student-Assistant in Physics and Electrical Engineering, and for one year after graduation, (1890-91), he was Assistant instructor of Electrical Engineering.

During 1891-1900, he was employed by the Westinghouse Electrical and Manufacturing Company of Pittsburgh. While with this company, Mr. Mershon became experienced in all branches of electrical work;—research work, both theoretical and practical,—experimental work, designing, factory engineering, field engineering and installation, patent expert work and patent experimental work, commercial work and selling. The transformers for which the Westinghouse Company received an award at the World's Columbian Exposition at Chicago in 1893 were of his design.

In 1893-95, he had charge of certain work being done by the Westinghouse Company in connection with the extension of the transmission plant of the Telluride Power Transmission Company of Telluride, Colorado. This was a single-phase, alternating-current transmission, employing single-phase, synchronous motors.

In 1896-97 for the Telluride Power Transmission Company and the Westinghouse Electric and Manufacturing Company he carried on at Telluride an investigation of the phenomena which occur between conductors at high voltages. This investigation was made on a transmission line about two and one-half miles long, and was the first investigation in which quantitative measurements of the ionization and other atmospheric losses occurring between conductors at high voltages were obtained. Original methods of investigation were devised by Mr. Mershon for this work, and special apparatus designed and built by him, by means of which quantitative measurements were made up to 72,000 volts. At the completion of the quantitative work, the voltage was carried up to 133,000 volts, at that time by far the highest voltage that had ever been impressed on an outdoor line.

In 1897-98, securing leave of absence from the Westinghouse Company, he acted as chief engineer of the Colorado Electric Power Company, during the designing and installation of their transmission plant which generates current by steam at Canon City, Colorado, and transmits power at 25,000 volts to Cripple Creek, Colorado, (a distance of 25 miles), where it is used for mining.

From 1898 to 1900, Mr. Mershon was engineer of the New York office of the Westinghouse Electric and Manufacturing Company, but during the latter year he resigned to enter upon private practise as a Consulting Electrical and Mechanical Engineer in New York City.

Some of the more important pieces of engineering work accomplished by him since entering practise as a Consulting Engineer are:

The reconstruction and enlargement of the water wheel, generating, transforming and transmitting equipment of the Montreal and St. Lawrence Light and Power Company (now a part of the Montreal Light, Heat and Power Company), transmitting to Montreal, a distance of 17 miles, 20,000 horse power at 25,000 volts;

The design and supervision of the first transmission plant of the Shawinigan Water and Power Company, transmitting power at 50,000 volts a distance of 85 miles to the City of Montreal.

The design and installation of the substation equipments of the Montreal Street Railway Company, having an aggregate capacity of about 12,000 horse power, for utilizing power transmitted to Montreal from various hydraulic plants;

The design and supervision of the transmission plant of the Niagara, Lockport and Ontario Power Company for transmitting power at 60,000 volts from Niagara Falls to various points in New York State. This plant is the largest transmission plant ever undertaken anywhere in point of capacity, and is one of the most important in point of distance of transmission. Its initial capacity was 60,000 horse power, and it is laid out for an increase to 180,000 horse power. At present its longest feeder is 160 miles.

The electrical design of the generating station, transmission line and receiving stations of the Inawashiro Hydroelectric Power Company, transmitting power at 115,000 volts from Lake Inawashiro to Tokyo, Japan, for use in the latter place,—a distance of 140 miles. The initial installation was for 45,000 kw.

In 1905, and for several years thereafter, he was retained on the work of the Victoria Falls Power Company, in connection with the installation of their steam stations near Johannesburg for supplying power to the gold mines of the Witwatersrand, and in connection with the proposed transmission of power from Victoria Falls on the Zambesi River, Rhodesia, South Africa, to the Rand, for operation in connection with these steam stations; being then the only American engineer so retained.

Mr. Mershon is the author of a number of technical papers, among which are "The Output of Polyphase Generators and Rotary Transformers," 1895. This paper contained the first published analysis of the effect upon the output of closed coil windings, when the number of phases is varied.

"Drop in Alternating Current Lines," 1897; treating of the calculation of drop and giving a table and chart by means of which such calculations can be quickly and accurately made.

"The Maximum Distance to which Power can be Economically Transmitted, 1904. This paper was presented at the International Electrical Congress at St. Louis in 1904, and was read before the American Institute of Electrical Engineers the same year. In presenting this paper at the International Electrical Congress, Mr. Mershon represented the American Institute of Electrical Engineers, acting as its delegate to the Congress.

"High Voltage Measurements at Niagara," his paper read before the American Institute of Electrical Engineers, June 30th, 1908, gives the result of some three years of investigation of the ionization and other atmospheric losses occurring between line conductors at high voltages. This was a continuation of the work previously done by Mr. Mershon at Telluride.

Previous to the entry of the United States into the World War, Mr. Mershon actively cooperated with those who formulated, and procured the passage of, the legislation creating the Reserve Officers Training Corps. Subsequently, when a Joint Committee of the National Engineering Societies was formed to work for the establishment of an Officers Reserve Corps he was a member of that Committee and active in the work which led to the passage of legislation creating the Corps. He was among the first of the Majors—then the highest rank in the Corps—commissioned in the Engineer Officers Reserve Corps.

When the United States entered the War, he was called to service and detailed to the Naval Consulting Board for the especial purpose of directing the work of the Special Problems Committee of the Board, which had principally to do with the problem of submarine detection. At the time of his retirement from military service he had the rank of Lieut. Colonel of Engineers.

He is a member and past president of the Inventors Guild and also a member of many American and foreign technical Societies.

The Development of the Sectional Paper-Machine Drive

BY H. W. ROGERS[1]
Associate, A. I. E. E.

Synopsis.—*To an increasing degree, large machines designed for quantity production are being subdivided into their elements, each section being driven by a separate motor as contrasted with former practise of driving these machines, as a whole, from a single unit. With the paper machine, this is called the sectional-electric drive.*

In this paper, the author has confined himself largely to the history and development of the several types of the sectional drive and the relative merits of each particular type.

An attempt has been made to set forth clearly the advantages of the sectional drive and to show that its field of application should increase with a fuller understanding of its advantages as to increased production, improved product and lower operating cost.

* * * * *

THE sectional drive, as it is commonly called, consists of a number of individual motors driving the various sections of a single machine with provision for maintaining a definite speed relationship between the sections, and while it is not limited in its application to paper machines, the use of it in this industry has been so extensive that it is impossible to mention sectional drives without immediately thinking of the paper industry.

The sectional drive is an extremely interesting engineering problem and is very important commercially, especially to the pulp and paper industry. Of approximately 1600 paper machines in use at the present time, probably 80 per cent are still being driven by means of the old type mechanical drive and steam engine, which would indicate that, in spite of the progress already made, the field of application for the electric drive has barely been entered.

The advantages of the electric motor are recognized, as practically all new mills are 100 per cent electrically equipped and most old mills use motors to a limited extent on pumps, beaters, jordans, screens, etc. However, the paper machine, the most important machine in the mill and the heart of a billion dollar industry, has been neglected. A vast amount of time and thought, research and development work, has been devoted to this problem by the engineers of some of the larger electrical manufacturers and, like all other new applications, developments, changes and refinements have taken place.

In a sense, these changes have come as the result of a broader knowledge of the problem and an honest endeavor to meet all of the requirements, but it is equally true that the paper manufacturers have gradually become more exacting in their requirements. In any event, change and development go hand in hand with progress; it is a natural process and should not be held out as a criticism.

To appreciate fully the problem which confronted the electrical manufacturer in 1919, it is necessary to consider the details of the paper machine and its requirements.

There are certain parts of every paper machine which run at a constant speed, regardless of the speed at which paper is being produced, and these parts, consisting of screens, pumps, suction and agitators constitute what is commonly called the constant-speed end of the paper machine. The driving of this end of the machine presents no difficulty whatever in its application and requires very little attention.

The variable-speed end of the machine consists of a number of separate sections, which have been in the past and are very largely at the present time being driven from a single line shaft through a system of cone pulleys and bevel gears with friction clutches for starting and stopping each individual section separately if occasion requires.

The stock enters the machine at the wet end on the wire and consists of 99½ per cent water and ½ per cent stock. Here the sheet is formed and, in three seconds, 99 per cent of the water is removed after which the sheet passes through one or more press rolls and over the dryers to the calenders, reel and rewinder as finished paper with about 8 per cent moisture, the whole operation requiring probably 40 seconds.

A continuous sheet must, therefore, be maintained throughout the machine and owing to its condition, there is a slight difference in speed between each section which must be maintained absolutely. This difference in speed is called "draw" and varies from time to time with the condition of the stock and the grade of paper and must, therefore, be capable of adjustment.

The drive must not only permit of a very close speed regulation, but must also permit of adjusting the "draw" between sections and at the same time absolutely maintain the relative speeds of the various sections.

The quality of the product depends very much upon the type of drive selected and the proper application of it with respect to the machine. Speed regulation, flexibility of control and uninterrupted service are all important factors and must be given careful considera-

1. Industrial Engineering Department, General Electric Company, Schenectady, N. Y.

Presented at the Regional Meeting of District No. 2 of the A. I. E. E., held at Cleveland, Ohio, March 18-19, 1926.

tion. For this reason it is desirable to have the paper machine and its drive a complete unit in itself, independent of the rest of the mill, so that trouble in the rest of the mill will not result in any interruption in the actual production of paper.

The line drawing, Fig. 1, illustrates the more common form of paper machine, consisting of the following sections:

1. Couch (either suction or standard)
2. First press (either suction or standard)
3. Second press
4. Third press
5. First dryer
6. Second dryer
7. Calender
8. Reel.

A fourth, and even a fifth press is sometimes encountered, and it is not uncommon to find a smoothing press with one or two breaker stacks and two or three calendar stacks, making a total of twelve or thirteen sections on one single machine. These sections, however, are practically independent of each other so that they are readily controlled, but on machines which involve felts common to two or more sections, the problem becomes complicated and both the paper manufacturer and the electrical manufacturer begin to court trouble.

The "draws" or slight variations in speed between consecutive sections are not fixed but are subject to modification due to the condition of the stock, kind of paper and suction; consequently, provision must be made to vary the speed of each individual section within certain limits (approximately 20 per cent) and still maintain a definite speed relationship between all of the sections. The approximate draws are indicated in Fig. 1.

The driving of a single machine with a multiplicity of motors, or a sectional drive as it has come to be known, is not a new idea, although the demand for it is relatively recent, beginning in 1919.

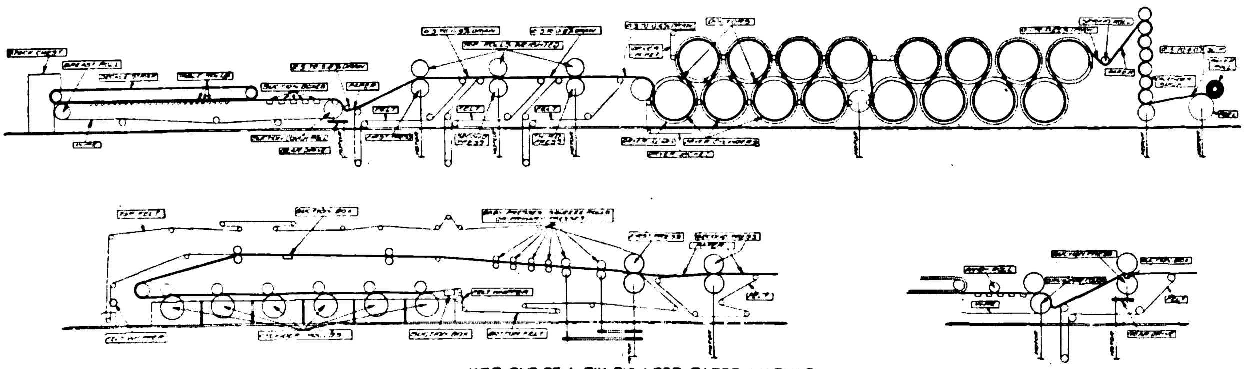
In 1909 the first real sectional drive was installed at the Chisholm Falls plant of the International Paper Company, consisting of d-c. motors with quarter-phase collector rings and mechanical speed changers for "draw" adjustment and, although it operated successfully for months, it was evidently in advance of the times and was eventually taken out.

In 1919 the enormous demand for paper, which had been aggravated by the curtailment of paper machine production during the war, started a controversy regarding the relative merits of wide, slow-speed machines and narrow, high-speed machines. Needless to say, the high-speed machine won out, although there is now a mild tendency to reverse that decision, and the demand for sectional drives was born at a time when most of the electrical manufacturers were not fully prepared to receive it.

It was frankly admitted among machine builders and operators that while the mechanical drive was a possibility on high speed machines, it was not at all practical on account of the high maintenance and this condition magnified the necessity for a solution to the problem.

There was no reliable power data available, since it was practically impossible to obtain any with mechanical drives; nor was there any accurate data on "draws" for the same reason. However, the need was urgent and the first so-called synchronous tie-in type of paper-machine drive, in spite of adverse criticisms and prophesies to the contrary at the Crown-Willamette Paper Company's Mill was built and put into successful operation. This drive was really the forerunner of the ever increasing demand that has spread over the entire country, including Canada, and its success has had a marked bearing upon the development of the industry and the attitude of the trade toward sectional drives in general. A failure at that time would have been a reflection upon the electrical industry as a whole and undoubtedly would have been a serious set-back to the sectional drive as such.

In theory this type of drive was all that could be desired; in practise it fulfilled all expectations and its success was duplicated in eleven other orders during the same year. These drives made it possible to secure a vast amount of valuable data heretofore unavailable, the careful analysis of which has had a great deal to do with the developments that have followed since their creation.



WET END OF A SIX CYLINDER PAPER MACHINE

FIG. 1—FOURDRINIER PAPER MACHINE

During this period drives of an entirely different character were being exploited, although not in such large numbers.

Strictly speaking, there are but two types of sectional drive on the market today:

I. The synchronous tie-in type of drive, wherein there is an actual interchange of energy between the various machine sections and where the relative speeds are held constant by synchronous motors. This, truly, is preventative rather than corrective.

II. The regulator type of drive, wherein the speed of the various sections is maintained by shunt field adjustment on the motors. It will operate on an angular displacement similar to Type I, if the regulator element is of the synchronous type, but there is no actual restraining power to hold the motor in place and the success or failure of this type is determined by the amount of angular displacement which causes the regulator to function and by the time element of the motor field.

The real difference between these two types of drive can readily be appreciated when the peculiar characteristics of the d-c. motor, operating at reduced voltages and speeds, are considered. The speed regulation at full voltage and full speed may be three or four per cent or even less, but, owing to the armature drop, it becomes extremely poor when operating at low speeds on low armature voltage. To maintain a constant speed under these conditions with a varying load requires a very wide change in the field strength which detracts from the motor torque at low speeds. In other words, a d-c. motor will not deliver as much torque under reduced armature voltages and this demands the use of over-capacity motors where the regulator type of control is used.

With the synchronous tie-in type of drive, the motor capacity need not be increased because the synchronous motors absorb the change in load and the d-c. motors may be operated at a fixed field. This type of drive, therefore, while higher in cost and space requirements has the advantage of smaller capacity motors and will hold the motor speed within extremely close limits even where instantaneous load changes are encountered, whereas the regulator type of drive requires a certain time element between the change in load and the correction. However, the regulator type of drive, which will be fully treated later in this paper, has been improved to a point where it meets the most exacting requirements of commercial operation and, despite the larger capacity driving motors which it requires for wide range machines, offers advantages as to first cost and space requirements.

Coincident with the development of the regulator type of drive, the synchronous tie-in drive, while remaining fundamentally the same, has passed through several stages of improvement.

I. The original type consisted of slow-speed d-c. motors with high-speed synchronous tie-in motors connected to the d-c. motor through a pair of cone pulleys and a gear reduction.

II. In the second development the cone pulleys and belts were eliminated and a high-speed synchronous motor with revolving stator frame was used, the stator frame being driven by a small adjustable-speed d-c. motor. This change reduced the space requirements and overcame the objection to belts.

III. The final development of this type of drive utilizes a slow-speed synchronous motor mounted on the d-c. motor shaft, thus eliminating the gear reduction.

On all three of these drives the synchronous motors were 20 per cent of the capacity of the main driving unit with 200 per cent pull-out torque either as a motor or as a generator; consequently, they could take care of a maximum load change of 40 per cent without exceeding their normal rating and still hold the speed within very close limits. The development of this type of drive is shown in Fig. 2.

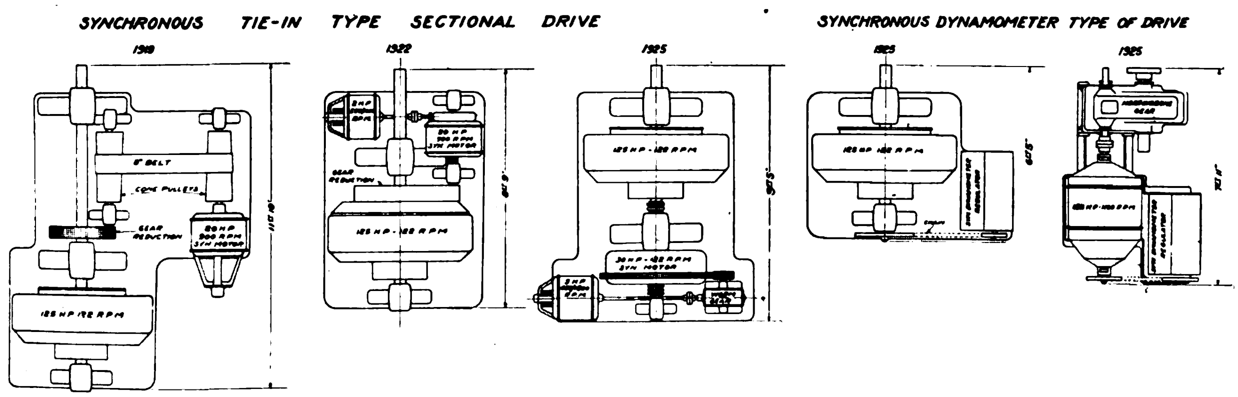


Fig. 2

It is a well-known fact that the synchronous motor operates at a fixed speed which is dependent upon, the frequency of the system to which it is connected and the speed cannot be changed so long as it operates within its capacity. The use of a multiplicity of synchronous motors connected to the same source of supply or interconnected between each other is analogous to a mechan-

ical line shaft and gears connecting the various sections of a machine together.

It is true that the loading of a synchronous motor is accomplished by an angular displacement between the rotor and stator, but it is equally true that a mechanical shaft with gears is subject to angular displacement under load.

The angular displacement in a synchronous motor is perhaps 10 or 12 electrical deg. under full-load conditions which corresponds to an angular displacement on the main driving motor of less than one-half of a mechanical degree. This displacement affects the sheet of paper that is passing over the roll at the time the load change occurs, and is present in all types of drive whether mechanical or electrical. It, however, is a negligible quantity and has no bearing upon the operation.

The original type of drive which has been so successful from the beginning has been installed on twelve paper machines, although one of them has since been

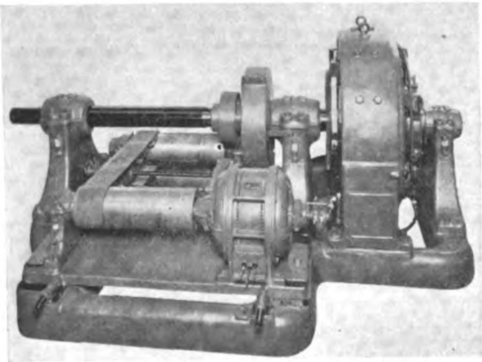

Fig. 3—First Development of Synchronous Tie-in Type of Drive Showing Moderate-Speed Synchronous Motor Connected to Main Motor Through Gear Reduction and Cone Pulleys

modified to the regulator type for the sake of uniformity in equipment. The use of cone pulleys and belts between the main driving d-c. motors and the synchronous tie-in motors has been questioned in a few instances on the basis that belts in ordinary commercial service operate with a slip of two or three per cent. However, the belts used on these drives are very much over capacity and under actual test show a maximum slip of $\frac{30}{100}$ of one per cent. The load on a paper machine is very constant and under normal operating conditions will not vary more than 10 per cent. Consequently, the speed is maintained with $\frac{15}{100}$ of one per cent or less, whereas the same load change on a mechanical drive would be twice this amount or even more depending upon the condition of the belts. Each synchronous motor is free to act as a motor or a generator with an actual transfer of energy between it and the balance of the synchronous motors. A load change on one section, therefore, may affect the speed of that section $\frac{15}{100}$ of one per cent, but the effect on the remaining sections, which must of necessity supply or absorb the energy, is only $\frac{2}{100}$ of one per cent on an eight section machine.

The second development of synchronous tie-in drive

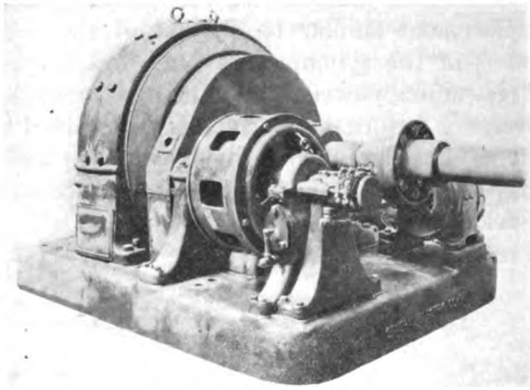

Fig. 4—Second Development of Synchronous Tie-In Type of Drive Showing Moderate-Speed-Geared, Synchronous Motor with Revolving Stator Frame

utilized a slow-speed d-c. motor to which a moderate-speed synchronous motor was connected through a gear reduction. The "draw" adjustments or speed changes,

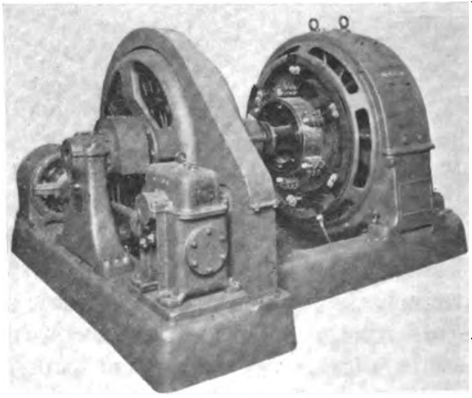

Fig. 5—Third Development of Synchronous Tie-in Type of Drive Showing Slow-Speed, Direct-Connected Synchronous Motor with Revolving Stator Frame

were obtained by rotating the stator frame of the synchronous motor by means of a small adjustable speed d-c. motor. This change eliminated the cone pulleys and belts and had the advantages of smaller space requirements and "draw" adjustment through the medium of a field rheostat rather than the shifting of a belt.

This type has been in successful operation since 1922 and has also been furnished on two other machines.

The third and final development of the synchronous tie-in drive utilizes a slow-speed d-c. motor and a slow-speed synchronous motor mounted on the same shaft. The "draw" adjustment is obtained by rotating the stator frame of the synchronous motor by means of a small adjustable speed d-c. motor. In this drive the cone pulleys, belt and the gear reduction are eliminated. This drive has been furnished for four paper machines which are motored for 1440 ft. per min., a speed far in excess of anything that has ever been attempted in the past on any machine.

In both of these developments where revolving-frame synchronous motors are used, the stator frame revolves at an extremely low speed compared with the rotor and consequently a speed change on the adjustable speed motors, which drive the stator frame, has little effect upon the speed of the section. In reality the regulation of the small d-c. motor only affects the speed of the stator which is but a small percentage of the synchronous speed. Consequently, the synchronous speed or the speed of the main driving motor will be maintained within $\frac{15}{100}$ of one per cent or less for the load changes ordinarily encountered on a paper machine.

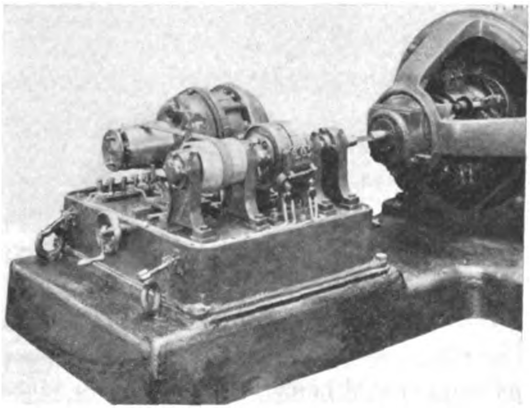

Fig. 6—Disk-Type Speed Regulator
As installed on sectional paper-machine drives

Fifteen of these drives are now in successful operation and most of them have been operating for five years with practically no maintenance.

The Synchronous Dynamometer (Regulator) Type

The possibilities of a speed regulator which operates on the shunt field of a d-c. motor have been fully appreciated and as early as 1920 a synchronous dynamometer type of speed regulator was built by the company with which the writer is connected.

This regulator consisted of a small synchronous motor, the rotor of which was driven from the motor on which the speed was to be held constant through a pair of small cone pulleys and a small belt. The stator was excited from a master generator in such a way that it remained stationary unless there was a tendency for the controlled motor to change in speed, thereby causing the stator to rotate and alter its field to maintain the speed constant. It operated on an angular displacement and handled the field current direct through a commutator type of rheostat, the brush mechanism of which was connected direct to the synchronous motor stator.

In 1921-1922, the disk-type regulator with synchronous motor actuating element followed closely on this development operating on the principle of a voltage regulator, except that the contacts were revolving instead of stationary. In its developmental stage the disks were modified to give a total angular displacement of 180 degrees and were so constructed as to cut the motor field resistance in and out of the field circuit twice every revolution or twenty times a second, the effective field resistance being determined by the angular displacement between the disks, one of which was driven by the motor to be controlled and the other by the synchronous motor. Subsequently, the brush mechanism was altered to cut the resistance in and out in three steps rather than one.

During 1922-23 this final form was furnished with ten paper machine drives, making newsprint, book, kraft, tissue, crepe and glassine; on high-speed machines and low-speed machines, for narrow-range and wide-range speeds. The regulator was subject to limitations in its operating range, under some conditions necessitating adjustments in an auxiliary field rheostat. This feature, however, only applied to wide-range machines and the endeavor to overcome it and make the adjustment of the auxiliary rheostat automatic resulted in one more development in which a mechanical differential was added to the disks to automatically adjust the external field rheostat. It was built and tested under actual operating conditions but has never been furnished on any drive.

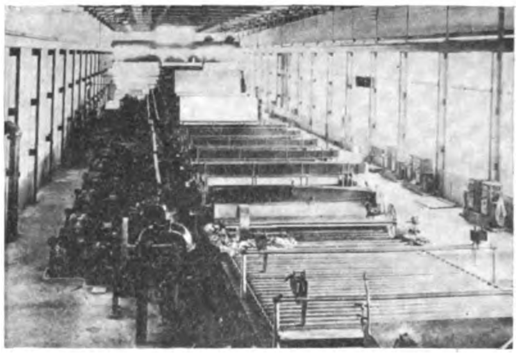

Fig. 7—Synchronous Tie-in Type of Drive with Cone Pulleys and Belts
As installed on a 164-in., 1200-ft.-per-min. paper machine

As a result of past experience with all kinds of paper machines making all grades of paper, it is believed that the speed regulator which will best satisfy the exacting conditions of operation and appearance is the development and refinement of the synchronous dynamometer regulator built and tested in 1920 and known as a synchronous dynamometer. It consists of a small synchronous motor, the rotor of which is driven from

the motor to be controlled through a pair of cone pulleys and a belt which gives 20 per cent "draw" adjustment. The stator frame, mounted on ball bearings is excited from a master generator and is free to rotate. It actuates the brush mechanism of a commutator type rheostat which has a total movement of 180 deg. The rheostat has both coarse and fine steps and gives the equivalent of 450 operating points.

This regulator combines a number of features not found in any other type of regulator:

1. Is of the synchronous type
2. It operates on an angular displacement corresponding to approximately 0.05 per cent change in speed of the controlled motor
3. Has 450 operating points
4. Has anti-hunting features
5. Has an absolute minimum of moving parts as the rotor of the synchronous motor, which is mounted on ball bearings, is the only moving part
6. The rheostat mechanism is stationary except when load changes demand action. It is not of the make and break contact type
7. Remains stationary, maintaining its operating position when the master generator is shut down or when the synchronous motor is disconnected from its power supply, thus overcoming any possibility of a "wild" machine
8. Has a wide operating range
9. Low maintenance
10. Minimum space requirements
11. Is totally enclosed
12. Is mounted direct on the motor base
13. Presents a neat compact appearance
14. Is readily accessible
15. Is rugged in design
16. Has motor-operated "draw" adjustment.

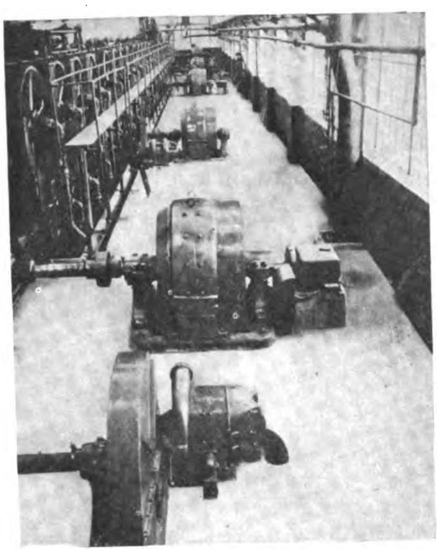

FIG. 8—REGULATOR TYPE OF SECTIONAL DRIVE
As installed on a 170-in., 700-ft-per-min. machine

It would seem that there has been an unusual number of modifications in the sectional drive but a careful analysis of the situation will reveal that there have been from the very beginning but two distinct types. The changes that have taken place are a natural process of development and do not affect the fundamental principle of operation.

Thus far only the development of the two types of drive and their characteristics as separate units have been given consideration, without any particular reference to the machine as a whole.

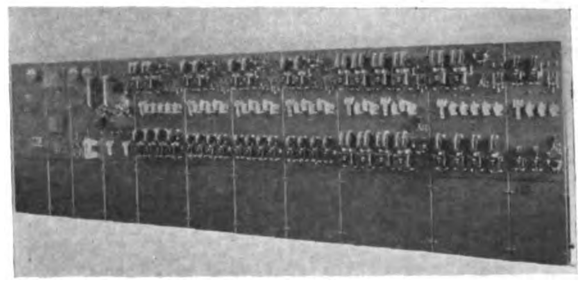

FIG. 9—CONTROL SWITCHBOARD FOR SECTIONAL PAPER MACHINE DRIVE

The sectional drive usually consists of the various parts as enumerated below.

I. A Turbo Generator Set.

(a) This has a separately excited shunt-wound d-c. variable voltage generator and a non-condensing steam turbine with a direct-connected exciter of sufficient capacity to excite the generator and all of the sectional motor units.

Exhaust steam is utilized to dry the paper and the turbine is designed to operate at back pressures to meet the required conditions. In some instance an a-c. generator is also furnished as a part of the turbine unit to furnish power to the constant speed end of the paper machine or to float on the mill system and thereby insure a perfect steam balance under all conditions of operation.

Synchronous motor-generator sets are sometimes used as prime movers and in such cases either live steam or exhaust steam from some other source is used to dry the paper.

(b) A generator-control panel

(c) A voltage-regulator panel with

1. A voltage regulator for the main generator
2. A voltage regulator for the exciter

(d) An auxiliary control panel for controlling the generator voltage and the speed of the machine as a unit.

II. Motor Equipment.

(a) An adjustable speed, d-c. motor for each section of the paper machine. This may be of the slow speed direct-connected type or of the moderate speed geared type. Both the open type motor and the enclosed, externally ventilated type motors have been furnished,

but this is entirely a matter of preference with the paper manufacturer.

(b) A regulator.

III. Mechanical Parts.

All motors are furnished with base, shaft, bearings, couplings, shaft extensions, and all necessary equipment not included as a part of the paper machine.

IV. Control.

(a) A five-point, full automatic-contactor control panel with overload and under voltage protection and indicating meters for each sectional motor unit.

(b) A continuous duty starting and regulating rheostat designed for 75 per cent speed reduction for each sectional motor unit.

V. Master Generator Set.

The master generator set which supplies a-c. power to the speed regulators consists of a 10-kw., 1200-rev. per min., three-phase, 60-cycle generator, direct connected to an over capacity d-c. motor which is controlled from the main generator panel and automatically comes up to speed when the voltage is brought up on the generator.

It controls the speed of the paper machine as a unit and its speed is adjustable within certain limits although it depends primarily upon the voltage at which the main generator is operating.

When the synchronous tie-in type of drive is used, the master generator is not necessary because any one or more sections which happen to be running constitute a master for controlling the speed of the other sections.

VI. Draw Adjustment.

Provision is made on each sectional unit for a sufficient "draw" adjustment to take care of all operating conditions such as variations in stock, grade of paper, grinding press rolls and the like.

The "draw" adjustment is motor operated and may be made from the front side of the machine.

VII. Temperature.

All equipment is based on 40 deg. cent. rise under normal load.

VIII. Location of Equipment.

The power unit should preferably be located in the basement under the paper machine and in close proximity to this unit the generator control and all of the motor control units may be lined up as a single switchboard. This arrangement leaves nothing in the machine room except the motor equipment and the control buttons.

IX. Operation.

In starting up the paper machine it is to be assumed that the motor-generator set or turbo generator set is running and that there is a proper voltage supply available. Each section of the paper machine may be started up in succession, starting with couch, by merely pressing a button after which the motor automatically comes up to its full speed or to a speed corresponding to the supply voltage and the speed regulator is automatically connected to the master generator bus and begins to function immediately.

Provision is made to operate the motors at slow speeds for washing felts, changing wires or spearing broke.

The individual control of the motors permits of operating any section of the paper machine independent of any other section and at the same time assures an absolute synchronous tie-in between the sections when all motors are operating at their full speed.

Slow-Speed Motors

It is not difficult to design for this service either slow-speed direct-connected motors or moderate speed motors with herring-bone gear reductions. Either type of motor is satisfactory and it is simply a matter of capitalizing the higher maintenance and increased space requirements of the moderate-speed geared motor as against the slightly higher first cost of the slow-speed direct-connected motor.

VARIOUS APPLICATIONS OF THE PHOTOELECTRIC CELL WITH AMPLIFIER TO PHOTOMETRY

At the Montreal meeting of the American Physical Society, February 26-27, Doctor Clayton H. Sharp presented a paper entitled "Various Applications of the Photoelectric Cell with Amplifier to Photometry" of which the following are excerpts:

A.—An arrangement whereby a photoelectric cell with a vacuum tube amplifier supplants the ordinary photometer head in making a photometric balance has been described before the Illuminating Engineering Society in September 1925. A rotating glass disk, one-half of which is silvered, throws in alternation the light of the "X" lamp and the light of the comparison lamp on to the photoelectric cell, the cathode surface of which is connected to the grid of an amplifying tube. If the two lamps differ in their effect on the cell, variations in the plate current are produced which act through a transformer and through a rectifying device upon a d-c. galvanometer.

B.—Spectrophotometry.

The filament of an incandescent lamp is focussed on a spectrometer slit, the beam passing through a variable sector. The photoelectric cell with amplifier is the detector. A circuit connection is used such that the galvanometer shows only the changes in the plate current. Spectrophotometric measurements of transmission are made by noting the deflection of the galvanometer when the filter is interposed in the beam, and then by means of the sector bringing the galvanometer to the same deflection when the filter has been removed.

C.—Temperature of Lamps.

The ratio of light transmitted by a blue filter to that transmitted by an amber filter as shown by the photoelectric cell varies with the temperature of the source of light. The temperature of incandescent bodies can thereby be determined, using a calibration curve.

The Use of Vibration Instruments on Electrical Machinery

BY J. ORMONDROYD[1]
Non-member

Synopsis.—*Several mechanical vibration instruments are described and actual problems which these instruments have helped to solve are mentioned. The theory of the seismographic instruments is developed to show the relation between the record or indication and the motion being measured. The limitations in the accuracy of amplitudes recorded or indicated are brought out.*

INTRODUCTION

VIBRATION problems in the shop have frequently been left to the care of "penny balancers," men whose practical judgment was not tempered by any accurate knowledge of the vibration properties of bodies or the possible causes of vibration. Their opinions were based on data gathered by the unaided senses of touch, sight and sound. The effects of vibration on the senses of touch and hearing depend on amplitude and frequency together; and it is well known that the eye exaggerates any vibratory motion it observes. Subjective data almost always fail in accuracy. Knowledge is useful only when it becomes quantitative. The question "How much" must be answered explicitly or implicitly before any action can be undertaken.

In any vibration problem there are five things which should be known:

1. Frequency of vibration.
2. Amplitude of vibration.
3. Type of vibration—simple-harmonic or complex.
4. The elastic properties and mass distribution of the vibrating body.
5. A general knowledge of the possible mechanical and electrical forces acting on the body.

The first three must be gotten by quantitative measurement. Observations of these three without measurement is usually valueless. The fourth is gotten from a knowledge of the materials and dimensions of the body. The fifth involves a clear understanding of the mechanical and electrical functioning of the body. This usually must go beyond the knowledge used to design the body since that knowledge, generally speaking, does not take into account the possibilities of vibration. No instrument can supply four and five. Trained human intelligence is necessary here.

It is proposed to show that this problem can be studied quantitatively in the shop and field. The theory and use of a few instruments suitable for this study will be taken up. Only mechanical instruments will be discussed. While electrical methods for measuring vibrations are well known the inconveniences attending the use of the oscillograph have always discouraged any extended application of these methods on machines in production and in operation. Mechanical instruments have the following advantages over electrical vibration measuring devices which depend on the use of an oscillograph:

1. They are easily portable.
2. They can be applied to the job quickly, easily and cheaply.
3. The record or indication is available for immediate use.
4. The record or indication can be taken over a long period of time.
5. No complicated electric circuits are needed.

It should be stated, however, that electrical circuits can be devised to give space-, velocity- and acceleration-time effects; while mechanical instruments are limited to space-time effects. Very high frequencies demand the use of electrical methods.

The theory and practise of five instruments will be given.

Indicating Instruments.

1. The vibrating reed.
2. The vibration amplitude indicator.

Recording Instruments.

3. The directly connected vibrograph.
4. The vibrograph.
5. The torsiograph.

The vibration amplitude meter as described in the paper was developed by engineers of the Westinghouse Company; although forms of this meter can be bought on the market. The other devices are commercial instruments widely used in Europe and slowly coming to the attention of American engineers. The use of each instrument is illustrated in the following pages by concrete examples.

The theory of the instruments is given in the appendices. Mechanical vibration-measuring instruments as they now stand cannot be used safely unless their limitations are clearly appreciated. The relationship between the record or indication and the actual motion is not a simple one. Knowledge of the theory of this relationship must be considered a necessary tool to the man who uses the instruments.

LINEAR VIBRATIONS

Most of the vibrations in electrical machinery are linear in nature. Four of the five instruments dis-

1. Motor Engineering Department, Westinghouse Electric & Manufacturing Company.

Abridgment of paper presented at the Midwinter Convention of the A. I. E. E., New York, N. Y., February 8-11, 1926. Complete copies available upon request.

cussed are for the study of linear vibrations. In general, the fields of application of these four instruments are:

1. The vibrating reed—for measuring frequency only.
2. The amplitude meter—for measuring amplitudes only.
3. The seismic vibrograph—used where a complete analysis of the motion is desired. Applicable where the instrument cannot be attached to a fixed reference point.
4. The directly connected vibrograph—used where a complete analysis is wanted. Applicable where the instrument can be attached to some fixed reference point.

Measuring Frequencies—the Vibrating Reed

The properties of resonance in a thin cantilever beam have long been used in turbo generator tachometers and electrical frequency meters. Fig. 1 shows a reed which can be varied in length and which can be attached to

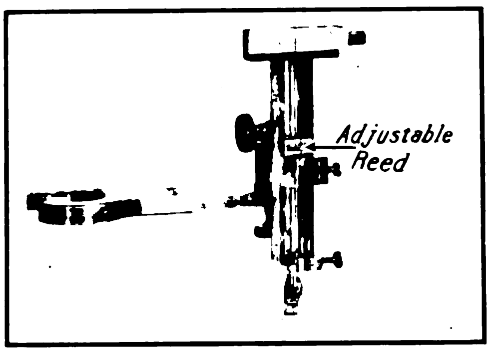

Fig. 1—Reed Vibrometer

any vibrating body. The body should have a weight considerably larger than the weight of the instrument, say ten times as great, to preclude the possibility of the instrument affecting the motion of the vibrating body.

The instrument shown in Fig. 1 consists of a claw to be clamped under a bolt head, two joints rotatable at right angles to each other, a main frame bearing a reed length scale on the side, an amplitude scale across the top and a long screw. A clamp carriage rides on the main frame; its position being adjusted by the screw. The reed is held tightly in a fixed clamp at the bottom of the frame and its free length is varied by the position of the movable clamp on the carriage.

The instrument is bolted to the vibrating machine and the free length of the reed is adjusted until the largest amplitude of motion is obtained at the end of the reed. This is read on the transverse scale. The instrument then is in resonance with the impressed frequency. This frequency can be determined by measuring the free length of the reed.

This device is so highly selective (damping forces extremely small) that it can be used only on vibrations with almost absolutely constant frequency. The least variation in frequency near the resonant point will give very large fluctuation in amplitude. This limits the instrument to uses on turbo generators and to cases where the cause of the vibration lies in magnetic pulls or in torque pulsations. These latter have frequencies depending on the voltage frequency of the line which varies slightly.

Given the same frequency, the amplitudes can be compared. Turbo generator balancing can be controlled by the use of a reed under these conditions.

A knowledge of the frequency of a vibration will often point to its cause. Unfortunately, the vibrating reed is too sensitive to be generally used for this purpose; since in most cases the frequencies vary enough to spoil the accurate setting of the reed.

The Measurement of Amplitudes Only—Amplitude Meter

In many cases the frequency of vibration is known and the magnitude of its amplitude is of importance. Here the amplitude meter is a handy tool. This instrument consists of a mass suspended from a frame by a spring. (See Fig. 12.) The frame is held against or attached to the vibrating body. The relative motion between the spring-suspended mass and the frame is equal to the total range of the vibratory motion when the frequency of the motion is above a certain value. This relative motion is transmitted through levers to an indicator which makes a band image over a calibrated scale.

The most important use for the instrument is in field balancing of turbo generators. The instrument is attached to the bearing pedestal and four amplitude readings are taken—one with the original unbalance; the other three with an arbitrary unbalance applied successively in three different points of the balancing plane. The amplitude readings determine a system of vectors which give the amount and direction of the original unbalance. This rational procedure saves time and is more accurate than the old cut-and-try methods.

In cases where periodic forces have set stators of electrical machines in vibration, the amplitude meter has been used to determine the nodes or points at which the stator motion amplitude was zero. A check on the number and position of the nodes, along with a measurement of the frequency, indicates the curative measures to be taken. It also indicates the accuracy of design calculations.

The comparative roughness of commutators can be gaged with a small amplitude meter by holding it on the brushes. Where a definite minimum roughness is permissible on a given line of motors, this is a simple means of inspection.

Where large numbers of any one motor have to be made with a given minimum of vibration, the amplitude meter again serves as a means of objective inspection.

Application of the Seismic Vibrograph

The seismic vibrograph is shown in Fig. 2. It consists of a heavy pendulum suspended between two springs. (See Fig. 13.) The pendulum is placed at right angles to the direction of the motion to be measured. The frame of the instrument is attached to the vibrating body and moves with it. The spring-borne pendulum stands still in space when the frequency of motion is above a certain value and the relative motion between the frame and the pendulum bob is transmitted through a system of levers to a recording pen. A strip of paper actuated by clockwork moves under the pen and a record of the motion shows as a wave on the paper. A timing device records equal time

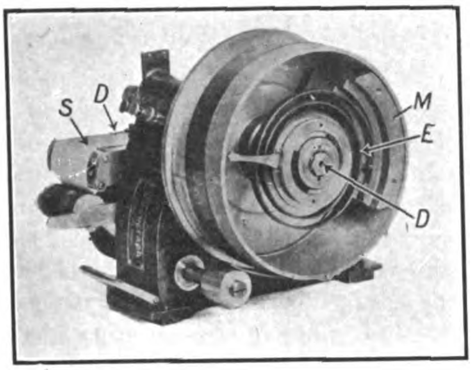

Fig. 2—Seismic Vibrograph

intervals on the same strip. The record can be analyzed for frequency, amplitude and type of motion.

The seismic vibrograph finds its chief application in the measurement of floor vibrations in buildings and electric locomotives. The absence of any fixed reference point in cases like these necessitates the use of a seismic instrument.

Although the cause of troublesome vibrations on factory floors or office buildings usually can be traced to its source without the help of instruments, there are cases where the cause is entirely elusive until vibration measurements are made. This is true where many pieces of rotating apparatus exist near together. A vibrograph record will show the frequency of the strongest vibration and this knowledge will usually point to the cause.

A common cure for floor vibration is mounting the machine which causes the disturbance on cork pads or springs. The design of a flexible mounting is determined by the weight of the machine and the frequency of the disturbance which it causes.[2] It is entirely possible to design a flexible mounting in such a manner that the transmitted vibrations become worse instead of better. In a rational design of flexible mounting the vibrograph supplies the necessary data on frequencies.

In gas or Diesel Electric Locomotives the floor vibrations may come from many sources. Unbalance in the reciprocating parts of the prime mover or in the rotating parts of the engine, generator and numerous auxiliaries—any one of these may be causing the objectionable disturbance. Usually they must all run simultaneously so no successive elimination of causes is possible. Another source of noticeable linear vibrations may be the periodic twist in the common foundation of the generator and engine due to the inherently varying torque of the prime mover. A vibrograph record usually shows up the troublesome frequency and leads to the proper remedy. This remedy may consist in the correcting of a bad unbalance, the changing of frame work structure to avoid local resonance, or the avoidance of resonance in the entire cab-spring system.

Application of the Directly Connected Vibrograph

Fig. 3 shows a side view of this instrument and Fig. 16 shows a top view. The instrument is clamped tightly to a body assumed to be absolutely stationary. A light rod transmits the motion from the vibrating body (See Fig. 16) to a bell crank which magnifies the motion and actuates the pen-push rod. The pen system, paper drive and timing device are all the same as on the seismic vibrograph (See Fig. 16).

The entire region close to a vibrating machine is often vibrating with the machine. In cases where this is so bad that the assumption of a stationary reference point cannot be approached even approximately special mountings for the instrument must be used. In power houses a heavy weight—a ton or more

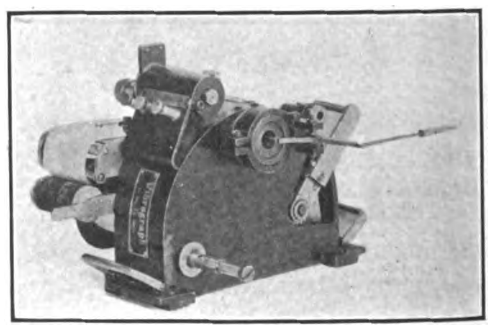

Fig. 3—Directly Connected Vibrograph

—is suspended from the crane and the instrument is mounted on the weight (See Fig. 4). On the test floor a heavy mass mounted on springs has been used. In both cases a seismic system is formed, having a low natural frequency which does not respond to the small high frequency forces transmitted through the bell crank. Usually the floor vibrations are small enough so that any object near the vibrating machine may be considered stationary enough to serve as a mounting for the instrument.

The Study of Critical Speeds

In rotating apparatus the critical speeds are the most important objects of vibration study. Existing methods

2. See C. R. Soderberg, *Elec. Journal*, Vol. XXI, 1924, p. 160.

of balancing rotors are accurate enough to eliminate violent vibrations at any speeds except those in the region of the critical speeds. The directly connected vibrograph finds its most extensive use in the study of the critical speeds of structures and machines.

Experimental Determination of Natural Frequencies

Any structure which is deformed by the application of external forces will return to its natural conformation, when these forces are removed, assuming deformations within the elastic limit of the structure. If the applied force is in the form of a blow the return to the position of static equilibrium is made through damped oscillations having the natural frequency of the structure. This fact is used in determining the natural frequencies of bodies too complicated in shape to be calculated. The

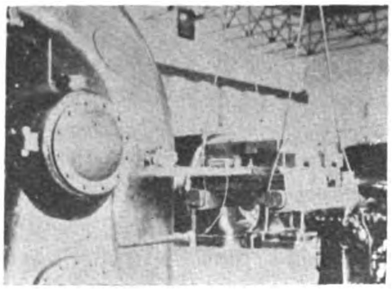

Fig. 4—Vibrograph for Powerhouse

body is clamped in its natural position, a blow is struck and the vibrograph records the ensuing damped oscillation.

The calculation of the natural frequency of turbo generator field structure is complicated by the presence of field winding slots. A method of calculating this frequency was devised analytically and checked experimentally by means of the vibrograph. The mass of the generator rotor is too large to be affected by a blow; so the principle of resonance was used. A small d. c. motor with a badly unbalanced rotor was mounted on the top center of the large rotor which was held in pedestals mounted on the test floor. The vibrograph was mounted below the center of the field. The motor speed was varied until the amplitudes of vibration of the whole field became a maximum. A curve of the amplitudes read from the records indicated the critical speed very distinctly and a check between theory and practise was possible.

Effects of Structural Parts on Critical Speeds

Perhaps the most valuable service which the directly connected vibrograph has performed has been in the emphasizing of the tremendous differences which can exist between the critical speed in rotating apparatus, as calculated on the rotor alone and the actual critical speed of the completed and installed machine. When a draftsman in the ordinary course of design calculates the critical speed of his rotor he tacitly assumes that the bearings in which it will rotate are held rigidly fixed in space and that his calculated critical speed will be the critical speed of the completed machine. But the action of the bearing under the influence of unbalanced forces depends on the flexibilities of the pedestals, bed-plate and ultimate foundation. These additional flexibilities, usually neglected, all tend to make the actual critical speed lower than the calculated speed.[3] This fact is of importance since all small and medium sized machines are usually built to run below their calculated critical speeds.

The effects of parts of the structure external to the rotor shaft may range all the way from complete control of the actual critical speed (as in the case of all modern balancing machines, where the flexibility connected to the vibrating bed determines the frequency of the system) to the case where the bearing is in extremely rigid pedestals attached to an extremely rigid foundation. In this latter case the critical speed as calculated would be the actual critical speed in service.

An extensive series of tests were run by Dr. S. Timoshenko and Mr. L. S. Jacobsen on an experimental synchronous condensor to prove that the effects of structural flexibilities could be predetermined accurately. The machine was rated 5000 kv-a. at 750 rev. per min. They tried three shafts of different diameters and two different bed-plates—all other conditions remaining constant. Bed-Plate B was 40 per cent heavier and twice as stiff as Bed-Plate A (See Table I). The results are shown in Table I.

TABLE I

			Bed-plate A		Bed-plate B	
Direction of Vibration	Diameter of Shaft	Critical Rev. per min. Calculated on Rotor Alone	Actual Critical Rev. per min. No Field Excitation	Per Cent Lower	Actual Critical Rev. per min. No Field Excitation	Per Cent Lower
Horizontal	10.5 in.	1270	1050	17%	1110	12.5%
	12.5 in.	1470	1180	20%	1270	13.5%
	15.5 in.	1820	1325	27%	1460	20.5%
Vertical	10.5 in.	1270	1010	21%	1110	12.5%
	12.5 in.	1470	1130	23%	1280	13. %
	15.5 in.	1820	1220	33%	1410	22.5%

Another interesting case was an experimental elevator motor generator set consisting of two standard d-c. machines, the rotors of which were on a common shaft and the stators being mounted separately on a common bed plate. The critical speed calculated on the rotor alone was about 3200 rev. per min. The actual critical speed was found to be at 1850 rev. per min. due to the combined additional flexibility of the feet and bed-plate. The system in reality was one with several degrees of freedom instead of one. By tying the two stators together with a brace, the feet flexibilities were elimin-

3. See C. R. Soderberg, *Elec. Journal*, Vol. XXI, No. 12, p. 579.

ated and the critical speed became 2800 rev. per min. (See Fig. 5.) When the inboard holding down bolts of one of the machines in the unbraced set were loosened only half of the foot material of that machine was acting as a restraint on its motion. This increase of foot flexibility lowered the critical speed to 950 rev. per min.

It can be seen that errors of critical speed calculation in the order of 40 per cent are possible in the ordinary course of design. This becomes important in case the designer thinks that he is running not far below the critical speed as he calculates it in the ordinary way.

Effects of Foundation. Synchronous machines have been tested on the test floor and in the field which showed a difference of 12 per cent. in the critical speed on account of the differences in foundations under the bed-plate. And in turbo generators, mounted as they are in power houses, several critical speeds are passed through in going up to the running speed some of which are due to flexibilities in the foundation itself. This problem is one of extreme difficulty and it is being studied by means of the vibrograph.

Effect of Magnetic Pull. Unbalanced magnetic pull also lowers the critical speed.[4] A mechanical spring always tends to return to its position of equilibrium

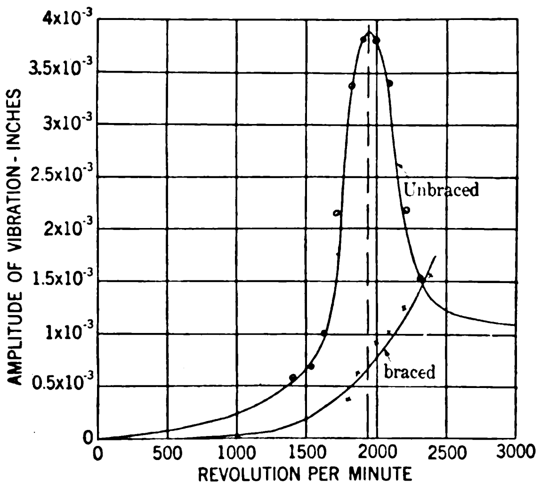

Fig. 5—Amplitude Curve—Rev. per Min. M. G. Set Vibration of Experimental M. G. Set with and without Brace

when stretched or compressed. A body in between the poles of a magnet is pulled away from its equilibrium position more and more, the farther it gets from the position of equilibrium. An unbalanced magnetic pull has a negative spring effect which decreases the total spring constant of the whole system.[5] For a given machine this can be calculated. For a certain field excitation, it reaches a maximum effect, for stronger fields its effect falls off again. In the case of the synchronous condenser mentioned before the maximum effect was at 30 amperes, field current. Table II shows the effects at this maximum taken from vibrograph records.

Vibrations not due to Critical Speeds

Noisy and violent vibrations cannot always be attributed to critical speeds. The case of an induction regulator standard for single-phase 60-cycles, but applied and rated for 25 cycles shows this very clearly. The machine was noisy on the test floor, due to impact between the segment teeth and the worm. The diagnosis of critical speed in resonance with the single-phase torque was made and the usual remedy of changing the shaft diameter was tried, but without diminishing the noise. The vibrograph was mounted to measure the tangential motion of the regulator gear segment. The supply frequency was varied and the kv-a. was kept constant. The resultant torsional vibration amplitude plotted from the records are shown in Fig. 6. Instead of resonance at 25-cycle voltage (50-cycle torque variation) the amplitudes tend

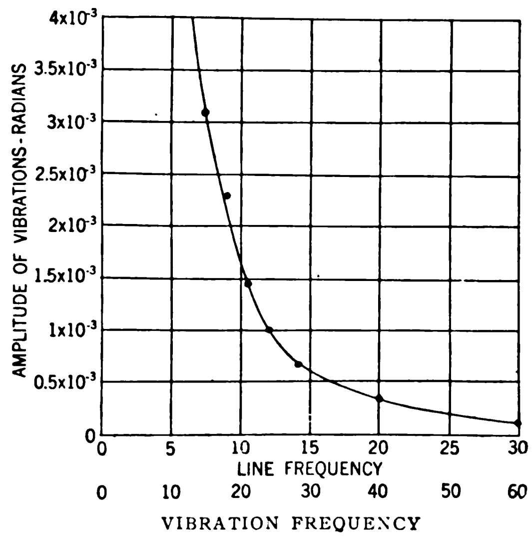

Fig. 6—Amplitude-Frequency Curve—Induction Regulator Vibration Frequency Cycles per Second

to increase toward infinity at zero frequency—or to some extremely low frequency resonance amplitude due to the clearances in the worm and segment system.

The rotor was acting very similarly to a rotor free to rotate in bearings acted upon by a periodic torque.

The amplitude of torsional vibration of such a body is in general

$$\theta_0 = - \frac{\phi_0}{I\,\omega^2}$$

θ_0 = amplitude of torsional motion
ϕ_0 = amplitude of applied torque (proportional to the kv-a. in this case.)
I = the moment of inertia of rotor
ω = $4\pi \times$ line voltage frequency

The only fundamental way to limit the oscillation was shown to be by the application of a fly-wheel to increase the inertia of the rotor. Since this could not be done gracefully or conveniently (and the idea of a fly-wheel on an induction regulator being revolutionary to say the least) the noise was cut out by putting longitudinal flexibility in the worm and making the segment from a non-metallic material. This decreased

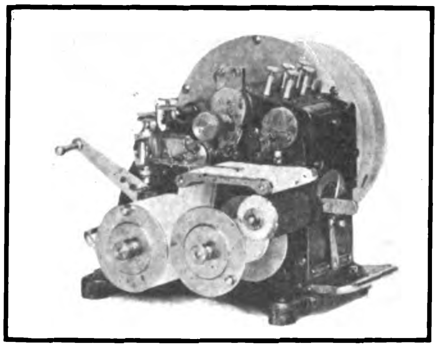

FIG. 7—TORSIOGRAPH

the deceleration value of the impact and completely eliminated the trouble.

The direct connected vibrograph has been used extensively in field balancing and in the study of magnetic noises due to stator vibrations.

TORSIONAL VIBRATIONS

Torsional vibrations although of common occurrence cannot be observed very readily even when they are of destructive magnitude. These small periodic angles of lead and lag superimposed on the constant advance of rotating parts are only noticeable when they cause chattering in gear teeth or give rise to linear vibrations on the foundation due to stator reactions. Most shaft and coupling breakage can be attributed to the dynamical stresses induced by unnoticed torsional vibrations. Where torsional critical speeds occur these stresses become very large. Although it is much easier to calculate torsional critical speeds than linear critical speeds, very few designers check this important point. Torsional vibrations being hidden are ignored.

The torsiograph has an important educational mission in emphasizing the existence of these oscillations in a concrete way. Its chief uses are in the study of torsional critical speeds, in the location of the causes of vibration and in the checking of design theories.

The torsiograph consists of a light pulley and a fly-wheel mounted concentrically on the same axis. (See Figs. 7 and 8.) The fly-wheel is held in a definite static relationship to the pulley by means of two opposing springs. (See Fig. 14.) Relative motion between the pulley and the fly-wheel about this position of equilibrium is possible. The relative motion actuates a system of bell cranks which move a recording pen push rod. The recording-paper drive and timing device are exactly the same as for the vibrograph. In addition to the timer there is a pen actuated by a solenoid which is excited by the making of a contact once every revolution of the body being tested. This indicates the instantaneous angular position of the body.

The pulley is belted to the shaft to be tested and follows its motions. The fly-wheel tends to rotate at a uniform average speed for frequencies above a certain value. The relative motion between the irregularly moving pulley and the steadily moving fly-wheel produces the record.

TORSIONAL VIBRATIONS DUE TO MECHANICAL CAUSES

Gear vibrations have been studied with the torsiograph—the most interesting conclusion drawn being that torsional vibration with a steady tooth contact frequency only occur when the gears are heavily loaded. This points to the fact that any dynamical theory of gearing must take into account the effects of deflections in the gear structure (the only thing that changes with load) as well as geometrical errors in tooth form and spacing.

GAS ELECTRIC DRIVE VIBRATIONS

The torque delivered by an internal combustion engine is inherently irregular, consisting of a constant average torque with a periodically varying torque superimposed. The relationship between the magni-

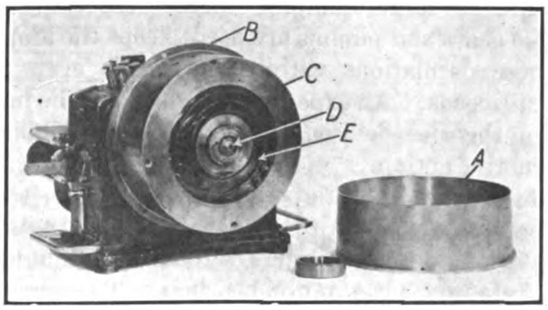

FIG. 8—TORSIOGRAPH

tudes of these two torques depends on the number of cylinders and the number of strokes per combustion cycle. The fundamental of the periodic torque has the firing frequency and all other higher harmonics also exist. The mechanical system consisting of generator rotor, fly-wheel and crankshaft with its attached reciprocating masses, has many natural frequencies. Theoretically the combination of the harmonics of the variable torque and the many natural frequencies of the rotational system lead to an infinite number of possible critical rev. per min. of the generating unit. Practically resonance with the fundamental and perhaps the second harmonic have given the im-

portant critical speeds. The other harmonics are usually too small to produce noticeable effects.

Several gas electric generating units have been investigated by means of the torsiograph—the critical speeds determined and operating speed limits have been established. The theories for precalculating the critical speeds have been checked experimentally by means of the instrument.

Where flexible couplings have been used on gas electric units records on both sides of the coupling have shown how the coupling acts as a wave filter, only the lowest harmonic of the variable torque being prominent on the generator side of the coupling and at speeds far above the lowest critical speed of the rotational system even the fundamental gets very small.

TORSIONAL OSCILLATIONS IN SIDE-ROD ELECTRIC LOCOMOTIVES

The torsional oscillation of the rotating system of a side rod electric locomotive is an important problem where locomotive frames, rods and cab structure are very light as in European practise. In the heavier American designs this problem loses much of its importance; but the careful designer attempts to make the possibilities of destructive torsional vibrations remote. The torsiograph has been used extensively in Europe in checking the numerous theories which have been developed on this subject. Theoretically, errors in side rod length (or "tram") errors in crank length and quarter, and pin clearances, can give rise to oscillation having driver rotational frequency, and the second and fourth harmonic of this frequency. Torsiograph records show that these exist; but the presence of large damping forces (especially where flexible gears and pinions are used) keeps the amplitude of these oscillations within safe limits even at the critical speeds. An experimental check can be made on design theories devised to lessen the possibilities of destructive action.

Where gears are interposed between the motors and drivers, resonance with the tooth frequency vibrations must be avoided on all parts of the motors and locomotive frame near the motor bearings. The torsiograph records show what conditions of load are necessary to bring about large amplitude of these gear frequency oscillations.

TORSIONAL VIBRATION FROM ELECTRICAL CAUSES

It is a well-known fact that single-phase rotating machines vibrate torsionally with double line-voltage frequency[6] and amplitudes proportional to the kv-a. The reaction of these single-phase torques through the stators of large machines have made it advisable in some cases to go to special spring mounting to protect the foundation of the machine from the double-line frequency forces.[7] The torsiograph makes a very convenient means of studying these oscillations.

It is generally assumed that polyphase motors rotate uniformly under all conditions. Torsiograph records in many instances show double line frequency torsional oscillation just as in the case of single-phase machines—the amplitudes being much smaller. Experimentally this was shown to be due to unbalance in the primary winding—unbalanced voltage or unbalanced impedance being equally effective. It can be shown theoretically by the use of symmetrical coordinates,[8] that the positive and negative sequence currents and voltage due to electrical unbalance produce a small torque of double line frequency superimposed on the average constant torque expected. The amplitude of the resultant vibrations is proportional to the amount of unbalance. Similarly it has been shown theoretically and experimentally that unbalanced resistances in the secondary of a wound rotor motor can produce destructive torsional vibrations on the rotor[9].

Unbalance in the secondary currents which have a fundamental frequency equal to the slip frequency will induce currents in the primary circuit having a frequency of $f - (n + 1)\, s$ where

f = line frequency
n = number of unbalanced secondary harmonic
s = slip frequency

Torques produced by a current having a frequency $f - (n + 1)\, s$ and a flux with frequency f will be of two frequencies $2 f - (n + 1)\, s$ and $(n + 1)\, s$.

This theory was developed by C. R. Soderberg and tested by him by means of the torsiograph and oscillograph.

In tying any a-c. motor onto a common shaft bearing other rotating masses the designer must be careful to avoid resonance with double the line frequency of the a-c. supply. This is especially necessary if the motor is single-phase; but should not be neglected even in the case of polyphase motors.

DIAMOND MINING AT NIGHT

An interesting application of modern electric flood lighting is in the Premier Mine in Transvaal, Africa, where the work of removing diamond-bearing earth is carried on twenty-four hours a day.

The mine extends over some 78 acres and at present has been dug out to a depth of about 500 ft. Excavations of diamond-bearing earth in the volcanic vent where diamonds are usually found are done in a series of terraces of 50-ft. depth. Since the mine has had to be worked day and night, it was necessary to supply efficient illumination. Arc lighting was tried but the blasting proved detrimental to the delicate mechanism of the arc lamps resulting in expensive maintenance. Now, electric flood lights housed in 14 huts are situated on the rim of the mine, with the rays projected from the rim to the working surface at distances ranging from 900 to 1600 ft.

Ionization Studies in Paper-Insulated Cables—I.

BY C. L. DAWES[1]
Member, A. I. E. E.

and

P. L. HOOVER[2]
Associate, A. I. E. E

***Synopsis.**—A research investigation of the ionization phenomena which occur in paper-insulated, high-voltage power cables is being made at the Harvard Engineering School under the auspices of the Impregnated Paper-Insulated Cable Research Committee. The paper presents some of the preliminary results which have been obtained, certain tentative conclusions that are suggested by the data and a description of the method developed for making the measurements. It is a preliminary report and in subsequent papers it is intended to record the progress of the investigation as it proceeds.*

The paper consists essentially of four parts as follows.

(a) A number of curves of power, power factor and capacitance taken on samples of cable at two frequencies and over a wide range of temperature. These curves show well-known characteristics, but in order to exaggerate these effects, cable models were made up to simulate the general conditions in a cable—one model consisting of glass and air only and another of glass, air and paper. Tests of these cable models gave very interesting results, particularly with reference to power factor. They also show rather clearly the baffling action of paper and the effects on power, power factor and capacitance when this baffling action is eliminated. In practically all the curves, the power and power factor begin to increase rapidly at a lower voltage gradient than the capacitance.

(b) Discussion of the results obtained and certain tentative conclusions which may be drawn from the results so far obtained and reported herein.

1. Ionization in the dielectric of an air condenser increases its capacitance slightly at first and then rapidly as the electron is separated from the atom. In our measurements we accordingly found that the power and power factor increase rapidly at a lower voltage gradient than the capacitance.

2. Ionization which occurs within air spaces in a dielectric may be called "restricted ionization" in that the current is limited because of the remainder of the dielectric in series.

3. With "restricted ionization," the voltage across each air space reaches a constant finite value with indefinite increase in the over-all voltage. The resistance of the ionized space, therefore, must be inversely as the current.

4. Consequently when this condition is reached, the ionization loss may be proportional to the charging current.

5. The increase of power factor with increase in voltage gradient with subsequent decrease of power factor is due to the fact that the capacitance of the solid dielectric, which is substantially constant, is in series with ionized air spaces whose resistances are inversely as the current. A simple mathematical analysis of this type of electric circuit shows that power-factor curves should have the form obtained in the measurements. Hence power factor alone is not a criterion of the degree of the completeness of saturation by compound.

6. Ionization by its bombarding action may destroy the baffling action of paper.

7. Ionization may produce potential gradients tangential to the surface of the layers of paper which, in conjunction with the bombarding action, may be the cause of the so-called "tree designs."

(c) Discussion of methods for measurements of this sort and a description of a new type of bridge which was devised for the measurement of dielectric losses at these extremely low power factors with the necessary high degree of accuracy. A large air condenser used as a standard and a vibration galvanometer of unusually high sensitivity and wide range of tuning were designed for use as a detector. The bridge is quickly and accurately balanced by varying a resistance and a mutual inductance. The angle of defect of the standard air condenser, although extremely small, is nevertheless very important in measurements of this character. This angle was measured by a substitution method and corrections made accordingly.

(d) Four appendixes discussing respectively (1) method of measuring defect angle of the standard air condenser, (2) mathematical analysis of a condenser of composite dielectric consisting of air and solid homogeneous material, (3) measurement of the high-voltage ratio, and (4) measurements of the capacitance, and other electrical constants of an ionized air space in series with a solid dielectric.

INTRODUCTION

THIS paper presents some of the results of research work being carried on at the Harvard Engineering School on the subject of Ionization Phenomena in the Insulation of High-Voltage Paper Cables. The work is conducted under the auspices of the Cable Research Committee, which is a subcommittee of the appropriate committees of the National Electric Light Association, the American Institute of Electrical Engineers, and the Association of Edison Illuminating Companies. The National Electric Light Association provides the Research Fellow for the work. The work is under the immediate supervision of a Cable Research Committee made up of members of the Faculty of the Harvard Engineering School, and one of the authors is Chairman of this Committee.

A summary of the more important results which have been obtained up to the present time is presented together with suggested explanations based upon the modern theory of ionization. However, an important object in presenting these results at this time is to invite discussion, from which it is hoped to obtain ideas which will aid in the further prosecution of the investigation.

PROCEDURE

The fact that ionization or breakdown of occluded air and other gaseous films exists in laminated insulation, such as impregnated paper as used in cables, has been known for some time. However, opinions and theories differ as to the exact nature of this ionization and its effects on the insulation of the cable as a whole. A fundamental object of our investigation is to determine, so far as possible, the exact nature of these ionization phenomena and to suggest in explanation a rationa

theory which can be substantiated by experimental data.

Naturally, our first procedure was to obtain experimental data on samples of commercial cables under various conditions of temperature, of frequency and of voltage gradient. From the analysis of these data it was hoped that some of the laws of the ionization taking place within the cables could be determined and a theory suggested to account for them.

In order to study such laws it is necessary to make measurements with a degree of precision much higher than is required for commercial testing. To obtain high precision in measuring such losses is not easy, especially at the present time when cables are designed particularly to have low dielectric loss and low power factor. Accordingly, before beginning the work, it was necessary to devise a satisfactory method of making the measurements. The authors investigated the various methods which have been described up to the present time and tried many of them. However, they were all found to be unsatisfactory because of their lack of precision or the difficulty in manipulation. After considerable experimenting, during which two or three promising methods were discarded, the one shown in the diagram of Fig. 1 was found to be the most satisfactory as regards accuracy, simplicity and ease of manipulation.

A simplified diagram of the bridge is given in Fig. 2. Referring to Fig. 1, the cable and a resistance R_2 of the order of 50 to 100 ohms for a 10 ft. length of cable, form one side of the bridge, while a standard air condenser C_1 and a resistance R_1 of the order of 1000 ohms form the other side. The primary of a mutual inductance M is inserted in series with the cable. The galvanometer G is connected in series with the secondary of the mutual inductance between points $c\ d$ of the bridge. The voltage drops across R_1 and R_2 are small, being of the order of one volt, so that no difficulty is experienced from the effects of the capacitance to ground of the detector. A simplified diagram of this bridge is given in Fig. 2. The cable is represented by the capacitance, C_2, and its equivalent series resistance, r_2. The standard air condenser is represented by the capacitance, C_1, and its equivalent series resistance is shown as r_1.

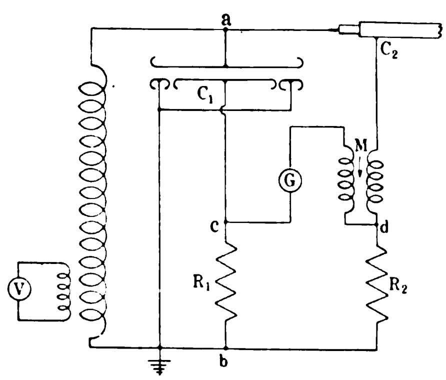

FIG. 1

The self-inductance L of the primary of the mutual inductance M is approximately 10 millihenrys, so that its impedance is small compared with that of the cable. Hence, in developing the equations for this bridge, the impedance of the primary of the mutual inductance M is neglected. In the equations for the bridge, let

$$\eta_1 = (R_1 + r_1)\, C_1\, \omega = \operatorname{Tan} \psi_1$$
$$\eta_2 = (R_2 + r_2)\, C_2\, \omega = \operatorname{Tan} \psi_2$$

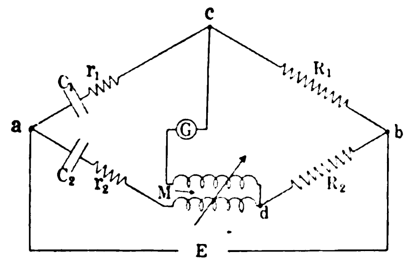

FIG. 2

A simple calculation gives for the conditions of balance:

$$C_1 R_1 = C_2 R_2 \frac{(\eta_1^2 + 1)}{(\eta_1 \eta_2 + 1)} \tag{1}$$

and

$$\frac{M\, \omega}{R_2} = \frac{\eta_2 - \eta_1}{\eta_1 \eta_2 + 1} \tag{2}$$

Since η_1 and η_2 are small compared to unity, the second order terms may be neglected and

$$C_1 R_1 = C_2 R_2 \tag{3}$$

and

$$\operatorname{Tan} \psi_2 - \operatorname{Tan} \psi_1 = \frac{M\, \omega}{R_2}$$

or

$$\operatorname{Tan} \psi_2 = \frac{M\, \omega}{R_2} + \operatorname{Tan} \psi_1 \tag{4}$$

If the condenser C_1 is a perfect air condenser, $\operatorname{Tan} \psi_1 = 0$, and ψ_2 is the angle of phase defect of the cable. If ψ_1 is not zero, the correction is simple.

Careful check measurements showed that our air condenser, although carefully insulated and guarded, did not have a phase angle of 90 deg. After considerable difficulty, the authors were able to obtain this angle at the lower voltages by a substitution method which is described in Appendix I. It was not possible for the writers to determine the angle at the higher voltages as they did not have a high voltage air condenser whose loss would remain constant when its capacitance was varied.

The bridge was balanced by varying R_1 and M, R_2 remaining constant. If the air condenser be assumed perfect.

$$\operatorname{Tan} \psi_2 = \frac{M\, \omega}{R_2} = \sin \psi_2$$

The power factor of the cable = cosine θ = sin ψ_2 which is sensibly equal to tan $\psi_2 = \dfrac{M\,\omega}{R_2}$, since ψ_2 is a small angle. Hence, for approximate work with the higher power factors the mutual inductance may be calibrated directly in power factor for any given frequency. This is a distinct advantage both in research work and in routine testing.

Considerable difficulty was experienced in obtaining a suitable detector. The detector must not only be sensitive but must have moderately high impedance in order to work properly with the bridge. The various standard types of vibration galvanometer were tried, but none was found satisfactory. Therefore, it became necessary to design and construct one. The moving iron-vane type, having an electromagnet for excitation, was found to be the most satisfactory.

With low voltages, or with small samples, the detector itself would not give the desired sensitivity. We, therefore, designed and constructed a three-stage resistance-coupled vacuum tube amplifier, which increases the sensitivity by something like 1000 times.[4]

With the foregoing apparatus it is possible to balance the bridge to measure phase angles to 0.001 per cent and detect even smaller changes. In view of the fact that the dielectric properties of the insulation which were measured are not constant, the foregoing precision is much greater than is necessary.

The voltage was measured by means of a voltmeter coil in the high-voltage winding of the 100-kv., 15 kv-a., 60-cycle transformer which supplied the power. The multiplying factor of the voltmeter coil was determined by a null method described in Appendix III.

The standard condenser consisted of two polished copper plates with rounded edges and corners. The low-voltage plate is guarded as is indicated in Fig. 1. The area of the working plate is 4 ft. × 5 ft. (1.219 m. × 1.525 m.). The distance between plates can be adjusted to suit the voltage, hence constant sensitivity is obtained.

The capacitance C_1 of the standard condenser was measured with a precision capacitance bridge. Knowing this capacitance and the resistance R_1, the capacitance C_2 of the cable is determined. It is then a simple matter to calculate the power, since the power

$$P = E^2\,C_2\,\omega \sin \psi_2$$

where ψ_2 is the angle of phase-defect of the cable. If ψ_2 is small, the power

$$P = \frac{E^2\,C_2\,M\,\omega^2}{R_2}$$

A 15-kv-a., 220-volt, 60-cycle alternator known to have a reasonably good sine wave[5] was used in all these measurements. Its voltage was controlled with a motor-driven field rheostat.

Measurements. Measurements were made at first on single-conductor cables having walls of insulation of approximately 20/32 in. thickness (16 mm.). Such cables would ordinarily be rated at 33 kv. Fig. 3 shows a typical power-factor curve obtained with a 500,000-cir. mils. cable having this thickness of wall. We noticed that at 50 kv. the rate of increase of the power factor became less. This has been observed by others[6]. At 60 kv. it apparently reached a maximum and then decreased slightly. This decrease of power factor in high-voltage cables after a maximum is reached has been known for some time among engineers.[7] So far as we know, however, no satisfactory explanation has been given for this character of power-factor curve. In fact, this decrease in power factor appeared to be contrary to the well-known explanations heretofore given to account for the increasing power factor

with increasing potential gradient. That is, the ionization commences in the air spaces adjacent to the conductors and occurs progressively in the air spaces from the center outwards as the potential is raised. In view of these uncertainties, it appeared to us that further study of this phenomenon might give some additional information as to the nature and effects of ionization in cables.

Schrader[8] also found with small air spaces in flat dielectrics that the power factor increased to a maximum and then decreased to a low value with increase of voltage.

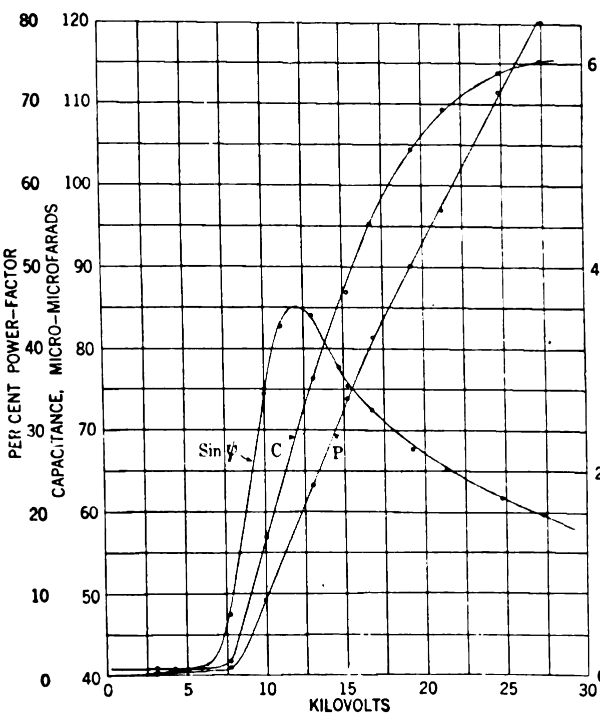

FIG. 5—CABLE MODEL. GLASS-AIR DIELECTRIC

20 deg. cent. 60 cycles per second

For purposes of study, we made a small cable model, Fig. 4 in which the ionization effects occurring in actual cables would be exaggerated. A glass tube having an inside diameter of 3.1 mm. and an outside diameter of 9.3 mm. was filled with mercury, the mercury forming the center electrode. A brass tube having an inside diameter of 14.3 mm. was placed concentric with this glass tube and insulated from it. The length of the brass tube between guard rings was 31.5 cm. Fig. 5 shows the curves of power factor, capacitance and watts loss obtained with this cable model at room temperature and at a frequency of 60 cycles per second. This is the character of curves which we expected the cables would have.

In order that we might obtain sufficiently high voltage gradients in cables to produce similar effects, it was found desirable to use smaller cable. Accordingly, a 00 A. w. g. (diameter = 0.418 in. = 10.6 mm.) single-conductor cable with a 9/32 in. (7.1 mm.) wall of insulation was used. In accordance with ordinary

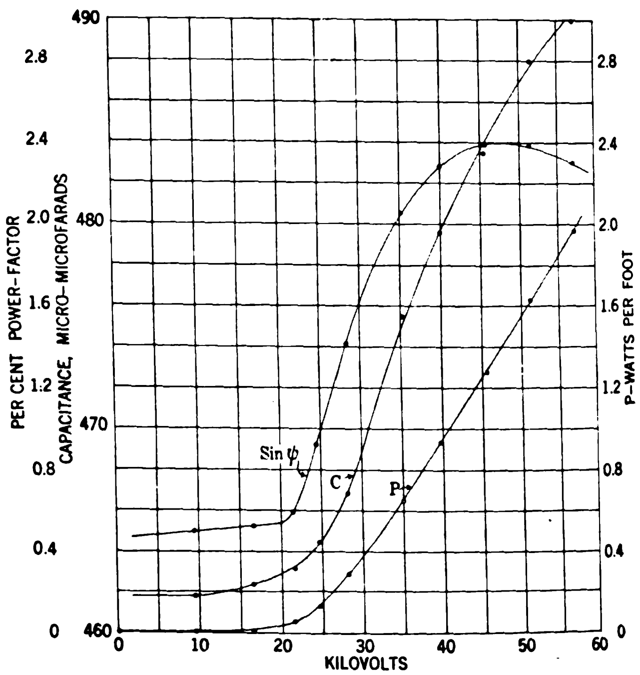

FIG. 6—IMPREGNATED PAPER CABLE. NO. 00 SINGLE CONDUCTOR

9/32-inch insulation. 20.4 deg. cent. 60 cycles per second

American practise, this cable would probably operate at 12 kv. The cable was guarded at its ends and end-bells filled with impregnating compound were fastened to the ends to prevent the compound from oozing out and air entering with change in temperature. The net length of cable tested was 7½ ft. (2.3 m.). Curves taken for this cable under various conditions are shown in Figs. 6 to 10 inclusive.

In Fig. 6, curves of power factor, capacitance and watts per foot are given for a frequency of 60 cycles per second and at a temperature of 20.4 deg. cent. as shown. At each reading sufficient time was allowed for the reading to become constant. It will be noted that the power factor after reaching a maximum value of 2.4 per cent actually does begin to decrease, as had been anticipated.

8. Schrader. "Corona in Air Spaces in a Dielectric." TRANS. A. I. E. E., Vol. 41, 1922, p. 583.

The difficulties in obtaining quantitative data on cable samples under these conditions of test are illustrated in Fig. 7, which shows curves taken at a frequency of 60 cycles per second and at a temperature of 53.8 deg. cent. The potential was first increased as before, readings being taken at frequent voltage intervals, and only after conditions had apparently become constant. When 58 kv. was reached the potential was decreased and readings taken at inter-

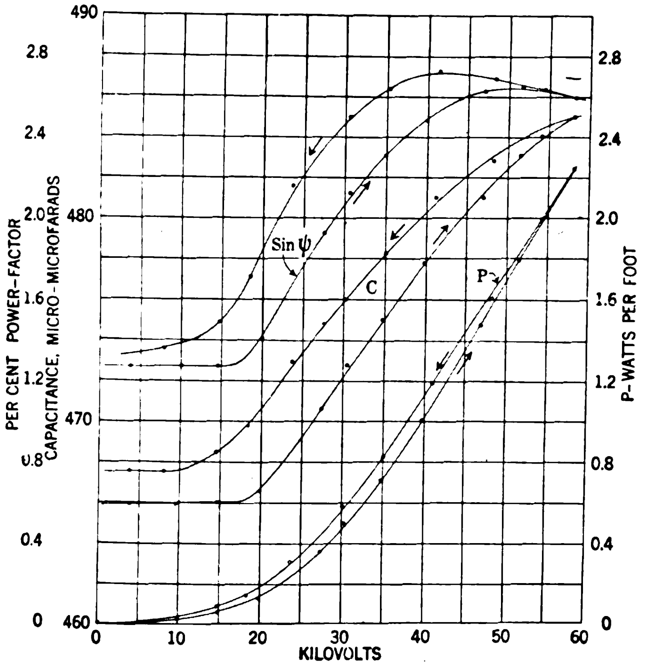

Fig. 7—Impregnated Paper Cable. No. 00 Single Conductor

9/32-inch insulation. 53.8 deg. cent. 60 cycles per second

vals to zero voltage. These readings, however, were taken immediately following each adjustment of voltage, a pause of only two or three minutes being necessary for taking each reading. Hence the dielectric was not given time to attain constant condition. It will be noted that the values of power factor, watts per foot and capacitance are all considerably greater for decreasing voltage than for increasing voltage. It should also be noted that with increasing voltage the watt curve and the power-factor curve begin to increase at a considerably lower voltage than the capacitance curve. Moreover, with decreasing voltage the curves reach constant values at lower values of voltage than they do with increasing voltage. Before taking each reading with decreasing voltage, if sufficient time for conditions to become constant be allowed, the values obtained are in most cases only slightly greater than the corresponding results with increasing voltage. In some instances, however, it has been found even when steady conditions are reached that the values with decreasing voltage are less than corresponding values for increasing voltage. We have also found that measurements vary considerably from time to time, even when taken under the same conditions. With impregnated paper insulation, for example, dielectric measurements frequently do not repeat themselves. On one occasion after completing a 60-cycle test, we found that the 25-cycle losses were greater than the 60-cycle losses even though sufficient time had been allowed for the cable to reach constant conditions. Due to such variations in the cable dielectric, great care must be taken if quantitative data are to be of value.

In Fig. 8 the solid lines are the curves of power factor and capacitance taken at 60 cycles but at a temperature of 88 deg. cent. It will be noted that the power factor increases rapidly when the potential is increased from 2 to 8.5 kv., at which point it reaches a first maximum. It then decreases, reaching a minimum at 15 kv. and again increases in the ordinary manner. This peculiar effect cannot be due to errors in measurement, since this portion of the curve was checked carefully. Moreover, this effect occurs only at high temperatures. It appears again in Fig. 9 taken at a temperature of

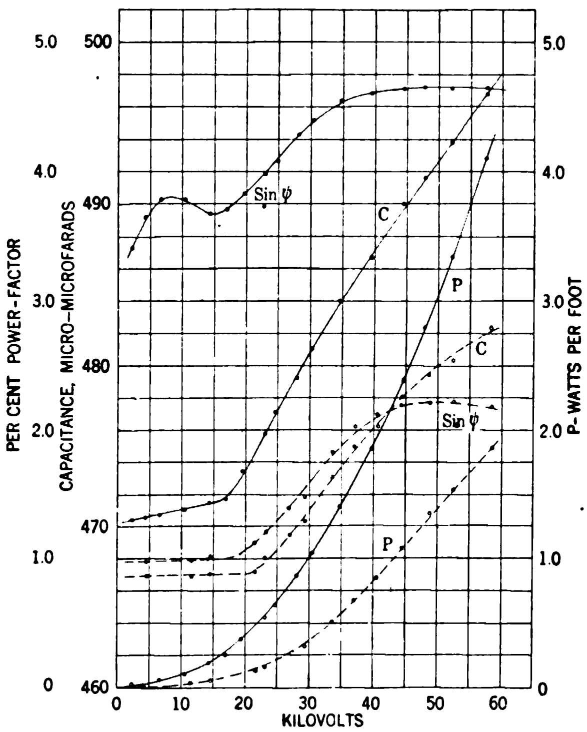

Fig. 8 —Impregnated Paper Cable. No. 00 Single Conductor

9/32-inch insulation. 60 cycles per second. 88 deg. cent. (Dotted curves are Fig. 10)

98.5 deg. cent. and at a frequency of 32 cycles per second. The authors are not prepared at this time to offer a definite explanation of this sudden variation in the power factor.

It will be observed at the higher temperatures that the range of maximum power factor is greater than at lower temperatures; also the power factor does not begin to decrease at as low a voltage as it does at the

lower temperatures, and further the decrease in power factor is not so marked.

In Fig. 9 the solid lines are curves taken at a frequency of 32 cycles per second and a temperature of 98.5 deg. cent. It will be observed that this power-factor curve has the same peculiar characteristic which appears in the 60-cycle curve, Fig. 8.

Fig. 10 shows a set of curves in which the watts per foot are plotted as a function of temperature, each curve being taken at a constant voltage. The frequency throughout is 60 cycles per second.

Analysis of Ionization Phenomena

Since the curves taken with our glass-tube cable model (Fig. 5) have all the dielectric characteristics

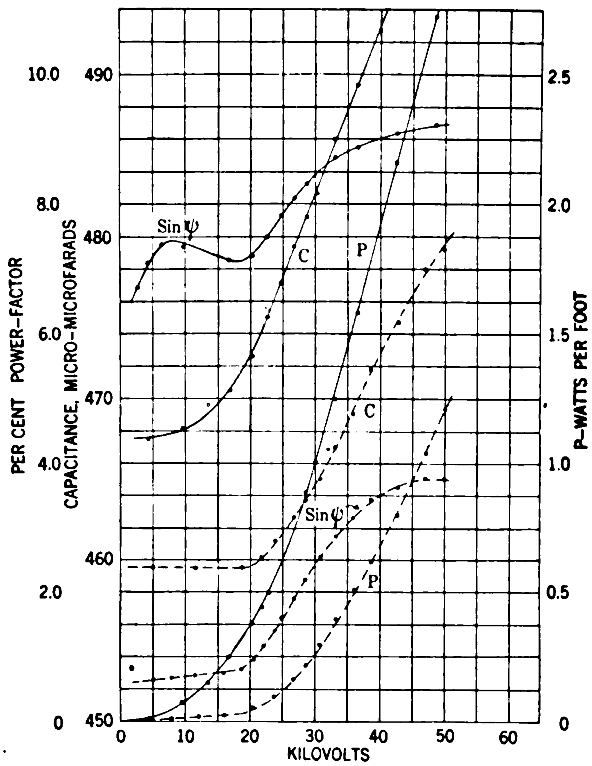

Fig. 9—Impregnated Paper Cable. No. 00 Single Conductor

9/32-inch insulation. 32 cycles per second. 98.5 deg. cent. (Dotted curves are Fig. 12)

of the actual cable, it seemed as if further data taken with such models might be of considerable assistance in the analysis of cable phenomena, particularly in view of the fact that the composite dielectric of glass and air is much simpler than that of paper, a compound of low viscosity, and air. Accordingly, another model similar to that of Fig. 4 was made and curves taken, Fig. 11. The glass of this model was slightly different from that of the first model, the curves for which are shown in Fig. 5. Aside from slight quantitative differences, these curves are similar to those of Fig. 5.

In attempting to analyze our own results, as well as those of Schrader, we found it necessary to know the effect of corona formation on the voltage gradient in air spaces and on the capacitance of air spaces. With the formation of corona about cylindrical conductors,

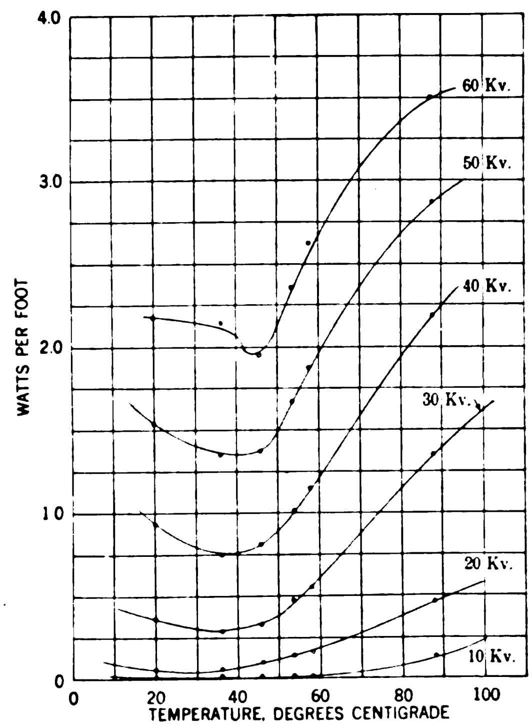

Fig. 10—Impregnated Paper Cable. No. 00 Single Conductor

9/32-inch insulation. 60 cycles per second

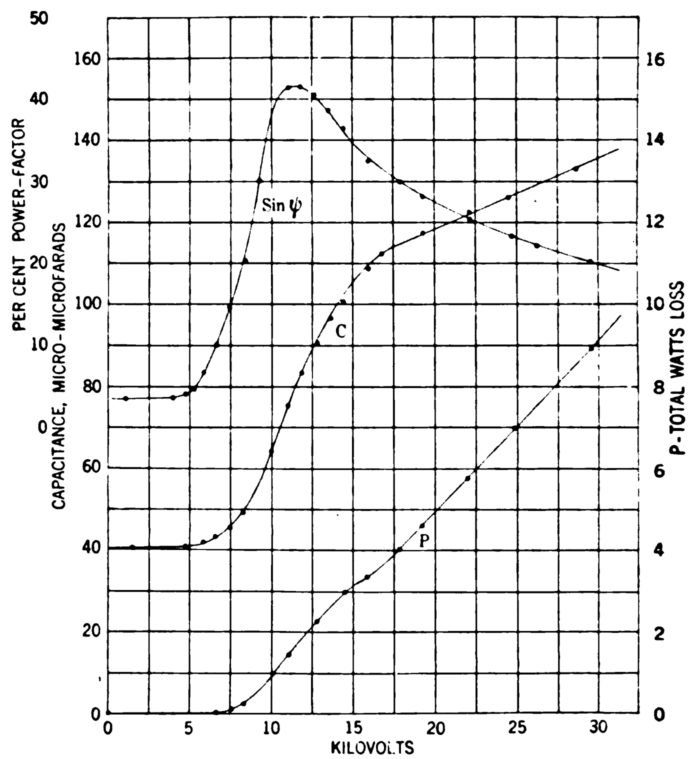

Fig. 11—Cable Model. Glass-Air Dielectric

20 deg. cent. 60 cycles per second

it has frequently been assumed that corona increases the effective diameter of the electrode[10]. This may

be true, but certainly this assumption must be qualified to the extent that this corona formation is not equivalent to increasing the diameter of the electrode in the sense that the voltage across the corona formation is negligible. Peek[10], later in his book, recognizes this fact for on page 85 he states: "Hence, corona seems to be either in *effect* a 'series resistance,' or it grades or distributes the flux density."

If, for example, in a composite dielectric of solid material and air, the voltage across the air spaces were neglected after corona is formed, the capacitance would increase abruptly at the critical gradient and immediately attain a nearly constant value. With our glass cable models, the capacitance should behave in almost this same manner when the gradient is sufficient to cause corona throughout the air space between the glass tube and brass cylinder. A study of Figs. 5 and 11 shows that this is not true.

So far as is known, no attempt has been made to determine the law connecting change in capacitance and ionization. Accordingly, some preliminary investigations of this phenomenon have been made by the authors and some of the results are given in Appendix IV. These results show that with a flat air space 2 mm. thick the capacitance of the air space when ionized reaches a value which is 28 times the capacitance for the non-ionized condition.

In addition to the increase in capacitance in the air films, when ionization takes place, the relation of voltage gradient to current also changes. To show in more detail the effects of this relationship, a reproduction of some curves given on page 267 of Townsend's "Electricity in Gases," is shown in Fig. 12. These curves show the current-voltage relation of air with parallel plate electrodes. The curves are taken for spacings of 2, 1, and 0.5 cm. The pressure in each case was 1.1 mm. of mercury and the initial ionization was produced by X-rays. These curves represent some of the first data taken in experimental work on ionization phenomena and are now considered quite elementary. Nevertheless, they are important in that they appear to offer explanations of some of the ionization phenomena which we have observed.

At low voltages, a current which, although very small, is finite flows through the air space. This current is due to the motion of the free ions and is practically independent of the voltage. In air, under ordinary conditions, this so-called "saturation current" is very small, and is practically negligible.

With increasing voltage the velocity of the moving ions increase and ionization by collision begins. As a result, the current increases rapidly, but there is no discontinuity in the curve. The curves have sharp bends, however, and after a certain voltage gradient is reached, the current density increases so rapidly with slight increases in voltage that we usually regard these curves as discontinuous and consider that the air has a definite breakdown gradient. It is important to remember that although the curves are not discontinuous with voltage gradients beyond the bend, the current density increases enormously with further slight increase in gradient. In the limit the current density becomes so great that sparkover or arc discharge results and the curve then takes a negative slope. With air films in solid dielectrics, the current is restricted by the solid dielectric in series with the air film, and the discharge does not go beyond the glow or corona

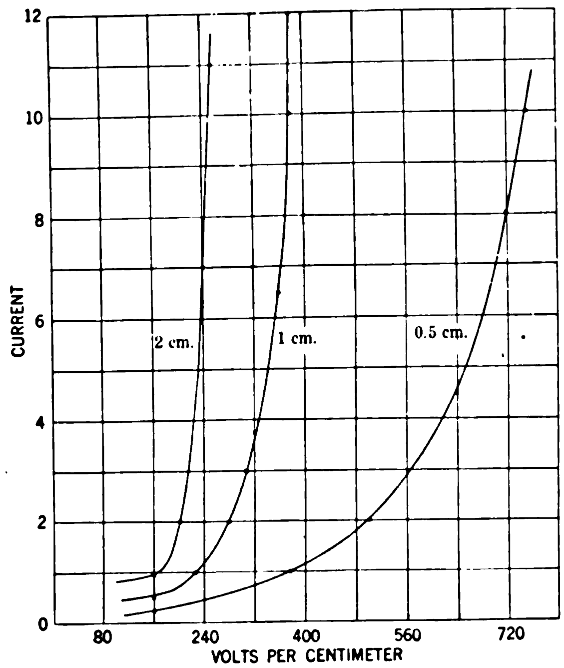

FIG. 12—CURRENT-VOLTAGE CURVES FOR AIR. PARALLEL ELECTRODES

1.1 mm. Hg. (Data from Townsend "Electricity in Gasses," page 267.)

formation, unless rupture of the entire dielectric occurs.[12]

From the curves, Fig. 12 it is apparent that for each spacing of electrodes the voltage gradient *increases* with the ionization current density until a limiting voltage gradient, which cannot be exceeded, is reached. With the 2 cm. spacing, Fig. 12 this gradient is approximately 180 volts per cm. and with the 1 cm. spacing it is approximately 300 volts per cm. With air, under ordinary conditions of temperature and pressure, this gradient is 30 kv. per cm. (maximum), except with very thin films.[13] With any current whose

magnitude is consistent with values of currents existing in dielectrics, such as are given in Fig. 12, the voltage gradient in the air is never zero. On the contrary, the gradient increases with increasing current density, approaching a definite maximum gradient for that particular air film. These effects have been verified by the tests made on ionized air, the results of which are given in Appendix IV.

Returning now to the cable models, let e_1 be the potential across the air dielectric, and e_2 the potential across the glass dielectric. Until the ionization voltage is reached, the potentials e_1 and e_2 will be inversely proportional to the normal capacitances c_1 and c_2 of the air and glass. Beyond this voltage, however, the potential e_1 cannot increase appreciably but must remain substantially constant. Hence, any further increase in the total voltage must be taken by the capacitance c_2. Curves illustrating this effect are given in Fig. 13, in which the voltages e_1 and e_2 are plotted as functions of the total voltage E. Each of the voltages e_1 and e_2 increases proportionately to E until 7.5 kv. is reached, beyond which point e_1 remains constant. For voltages greater than this critical voltage, any increase in E produces in equal increase in e_2. This assumes that e_1 and e_2 are substantially in phase. This is not strictly true, particularly at large values of E, as e_1 tends to come in phase with the current because of ionization losses in the air space. This would only change the slope of e_2 without changing its general character.

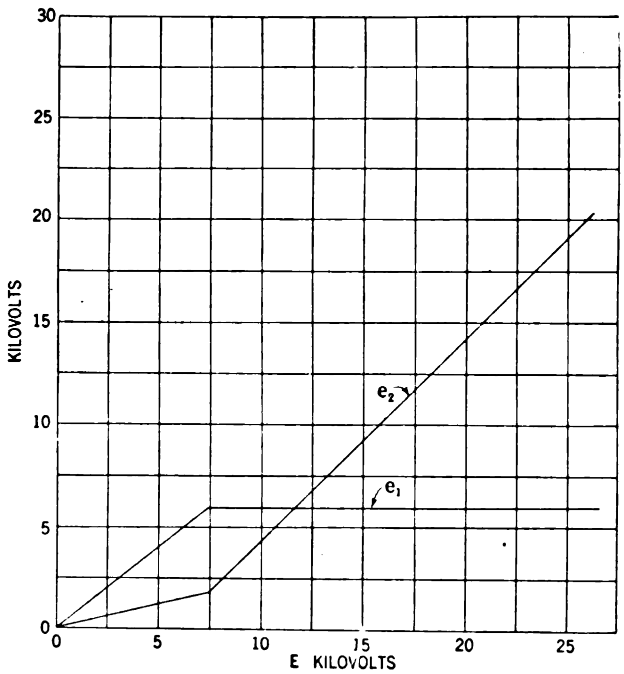

FIG. 13—VARIATION OF e_1 WITH TOTAL VOLTAGE, E

It seems reasonable, therefore, to conclude that corona in gaseous films produces a definite limiting gradient in the film, which depends on the nature of the gas, the pressure, the temperature and the geometry of the film. The current density in such an ionized gas does not depend on the voltage across the film, but rather on the impressed voltage and the remainder of the dielectric circuit. That is, the solid or non-ionized dielectric will limit the current density and it cannot increase indefinitely, as is indicated by the curves of Fig. 12 until rupture of the entire dielectric occurs.

This gives a condition which may be considered as *restricted ionization.*

Decreasing Power Factor. Schrader,[8] in explaining the decreasing power-factor with increasing voltage, which he obtained, states that it "indicates that saturation of ionization is approached." Our ordinary understanding of the statement "saturation of ionization" is that practically all the molecules have become ionized and the resulting ions and electrons are acting as carriers of electricity across the gaseous film. Calculation shows that this condition cannot exist in such air films. For example, if it be assumed that there is but one electron per molecule carrying the ionization current, the current density through the ionized gas would be several amperes per sq. cm. Obviously, no such current density is possible in air films within dielectrics.

Proos[6] plotted conductance against kilovolts and obtained curves very similar to power-factor curves. but consisting of three straight lines.

Clark and Shanklin[9] plotted "specific resistivity (effective)" or P/E^2, or the equivalent shunt resistance of the cable, against kilovolts. (This is the reciprocal of the quantity which Proos plotted.) They explain the lesser rate of decrease of their curves as follows:

> "Gradually a point of saturation is reached and the energy consumed by ionization approaches more nearly a true ohmic loss."

Shanklin and Matson[14] explain similar characteristics as follows:

> "Complete saturation is not yet reached, but the curve is flattening out, showing that the majority of the gas spaces have been ionized."

Although these statements are in a sense correct, we do not feel that they are adequate explanations of the phenomena. Even though ionization is a contributing cause, the character of these curves is not determined solely by the degree of ionization, but rather by the changes, due to ionization, in the constants of the series condensers consisting of the solid dielectric and the air films.

The equivalent circuit of the solid dielectric and air space is shown in Fig. 14, in which c_1 is the capacitance of the air space and r_1 is its equivalent shunted resistance; c_2 is the capacitance of the solid dielectric and r_2 is its equivalent shunted resistance. It can be shown

14. Shanklin and Matson, "Ionization of Occluded Gases in High-Tension Insulation," TRANS. A. I. E. E., Vol. XXXVIII, 1919, p. 489—See page 494.

that the sine of the angle of phase defect of the combination is

$$\sin \psi = \frac{e_2 \sin \psi_2 + e_1 \sqrt{1 - \dfrac{(e_1 c_1)^2}{(e_2 c_2)^2}}}{E} \qquad (5)$$

where e_1 and e_2 are the voltages across c_1 and c_2, E is the total voltage and ψ_2 is the angle of phase-defect of the solid dielectric. (See Appendix II.)

Below the ionization voltage, $e_1 c_1 = e_2 c_2$ since e_1 and e_2 are substantially in phase with each other, hence the radical is equal to zero and the power factor equals

$$\sin \psi = \frac{e_2 \sin \psi_2}{E}.$$
